COAL AGE

Vol. 1 NEW YORK, OCTOBER 14, 1911 No. 1

Foreword

THIS first issue of COAL AGE is the realization of a long cherished ambition to give the coal and coke industries, employing 1,000,000 men, a weekly journal devoted exclusively to their interests. The necessity for an independent, adequate organ has long been acknowledged, and we intend to fill that need.

The work, although conceived as a business venture, is supported by fraternal love and an everlasting desire for the betterment of conditions in and about our mines.

Digging coal may not be exactly what Sherman called war, but if Hades is any darker or dirtier, and if the imps down there get any blacker, then we don't want to wait until New Year's to make good resolutions.

Now, Mr. Miner—You who forsake sunlight and who toil along underground day after day to furnish coal, the life sustainer of every industry, remember, we are interested in you. No matter whether you are drilling and shoveling at the face, or whether you are building brattices or fixing track, your success is our success, and COAL AGE will be devoted to a campaign seeking your betterment.

Although, in truth, contentment is seldom measured by money, the chances are you would change places with the fellow who owns the mine you work in, and, quite likely, if happiness be thus sought, you would be loser in the swap; however, most all of us are wanting the very things we can't afford, so we might as well accept the world-standard, and concede in part that "Money is success"; therefore, it is better to be fireboss or mine foreman than digger, and if you are already fortunate enough to hold one of the former positions, it is still more desirable to be superintendent or manager.

Right here is where we enter, for if you can read English, and have enough ambition to entitle you to recognition, COAL AGE will furnish you a schooling that will make it easy to climb to better things. Do your part—bear in mind that this journal each week will represent the best efforts of a large corps of experienced engineers; study the matter presented and you will find at the year's end, the time consumed has been well employed.

Write us your needs; state your problems; you will help us and the other fellow as well as yourself. You have muscle, health and heart—great assets; however, your head will carry you further than your hands.

Mr. Mine Manager and Mr. Engineer:

You have attained your present responsibilities largely through knowledge gained from the experience of others. The greatest advances in the coal industry have resulted from a broad exchange of ideas. Without resorting to oratory or idle boasts, we want to say that the foundation has been laid to make COAL AGE the greatest of all mediums for the interchange of coal-mining information. Every detail of European practice will be brought to you so long as that field leads us in any phase of the art.

This is not a paper for miners only, nor is it intended solely for men higher up; each individual can skip all that doesn't interest him, and still have plenty to occupy his time and thought. If questions and answers and elementary discussions of basic principles, that are prepared to aid the ambitious man who has lacked educational advantages, seem trivial, and you believe will not add to your enlightenment, then for the love of the lives of the men at the face, encourage, rather than condemn us. The calm of a peaceful day will be broken for many of you, because of a lack in the learning of some man lower down.

With your co-operation, we will be instrumental in putting the industry on a higher, safer footing. Your friendship is sought, but your confidence is desired above all. We will persist in our right to be independent even at the expense of criticism and censure. Realizing that, "A friend to all is a friend to none," we expect opposition; such, however, will but add zest to our work.

Now, when we disagree, and that may be often, we earnestly ask your forbearance. Perhaps our judgment is at fault—probably we have been misinformed; whatever the cause, we want you to know there are no rights reserved us and denied you. Our pages are open and criticism is more sought for than praise.

We will be around to see you and talk with you, time and time again; no plant worth visiting will be overlooked, and if you have anything to show, whether far or near, just send us word.

We intend, therefore, to see things first-hand, just as you do, and we trust that our point of view (always, if possible) will coincide with your own.

One word more—COAL AGE is before you; there has been no extra effort made to dress up just because it is our first appearance. We know this initial issue will not measure above the average—in fact, it is quite certain that before long the size and scope of the paper will be materially enlarged.

Anthracite and Bituminous Mining

By Eli T. Conner *

A comparison of the methods used in the two fields for the mining and preparation of coal, with an account of the different modes of occurrence, conditions and market requirements. In some cases the northern anthracite field might copy the methods of the bituminous regions. This is the first of a series of articles by Mr. Conner.

The title of this article would appear to cover an enormous field of investigation and description, but it is not intended to give detailed reports but to refer briefly to the most important features of mining in the anthracite and bituminous fields of Pennsylvania and elsewhere, and to make comparisons where possible, of the methods pursued. Attention will first be given to the anthracite fields of Pennsylvania.

As is well known, mining on a commercial scale, was commenced in this region in the early part of the last century. The first known record of the organization of a coal-mining company in this field was in 1792, when the Lehigh Coal Mining Company was chartered, this being the origin of the Lehigh Coal and Navigation Company, which has been continuously in existence from that time down to the present. The first shipment of coal by this company was in 1802, when two ark loads of coal were floated down the Lehigh and Delaware rivers, to Philadelphia. Some of this coal was used for gravel walks on account of lack of knowledge as to the proper method of burning it. In the northern anthracite field, which will be the first discussed, in this series of articles, the Delaware & Hudson Canal Company was organized in 1823, and mining was commenced at Carbondale.

The northern anthracite coalfield extends from Forest City, in Susquehanna county, to Shickshinny, in Luzerne county, a distance of about 55 miles. The maximum width of this basin is 6 miles. The geological features of the northern anthracite field differ from the other anthracite fields in that the measures are comparatively flat; consequently it must be treated independently, and this article will be devoted exclusively to that region.

In order to illustrate the position of the various beds of coal underlying the Lackawanna and Wyoming valleys, I have incorporated four cross-sections, which are typical of the northern anthracite field, and give some idea of the methods adopted for the development of this wonderful deposit of anthracite coal. These cross-sections are taken from the Second Geological Survey of the State of Pennsylvania.

In the infancy of the business, our forefathers were confronted by many difficulties which we, of this generation, are sometimes apt to forget, when we criticize the methods they were compelled to adopt in order to develop a profitable business. I think it proper and right to make this statement, as in the progress of the article, it will be found necessary to make some criticisms which I believe are necessary for the improvement of mining methods.

As was quite natural, the earliest openings were made in what were believed to be the best, thickest and cleanest beds of coal and those which could be attacked by drift openings from the surface. For the ultimate winning of the maximum amount of coal, contained in the territory, this method was entirely proper where such beds of coal were the uppermost, but in most cases, throughout the northern anthracite field, the beds first developed were beneath others; the consequence of which is that, in many instances coal in overlying beds has been made irrecoverable.

The mining developments in the northern anthracite field and elsewhere, were first largely projected by men from England, Scotland and Wales, and most of the miners and laborers employed in these early developments came from the above-named countries, supplemented by Irish and Germans. Most of these pion-

*Mining engineer, Real Estate Trust building, Philadelphia, Penn.

eers had learned coal mining in their own countries, and naturally adopted in this country methods which had been found suitable at home. These pioneers, as I have before said, met and overcame great obstacles in the early days of the industry, and left their stamp upon the whole anthracite region. Many of the methods which were inaugurated in those early days have, with modifications, come down to the present.

Almost without exception, the room-and-pillar method of mining has, from the beginning, been followed in the anthracite field. It was found that if about one-third of the coal was left in for roof support in the form of pillars, it was sufficient, and this proportion ruled to a very large extent and has been continued down to recent times. In fact, according to my observation, it has been adhered to, in many instances, where it was entirely inapplicable. As is well known, the relative proportion of pillar coal that should be left for the support of varying thicknesses of overburden has not been definitely determined. Because each coal bed has peculiarities of its own which affect its crushing strength, and because, further, the character of the overlying measures varies greatly, no hard and fast rule can be laid down to determine the percentage of pillar coal which should be left in, but each property and even each portion of any particular tract of land, must be considered entirely by itself, to determine this point.

The room-and-pillar method of mining which has been very generally adopted in the northern anthracite field, and with very few exceptions continued to the present time, is quite well illustrated by the cuts incorporated, which are taken from the contribution of H. H. Stoek, to the 22nd. annual report of the U. S. Geological Survey.

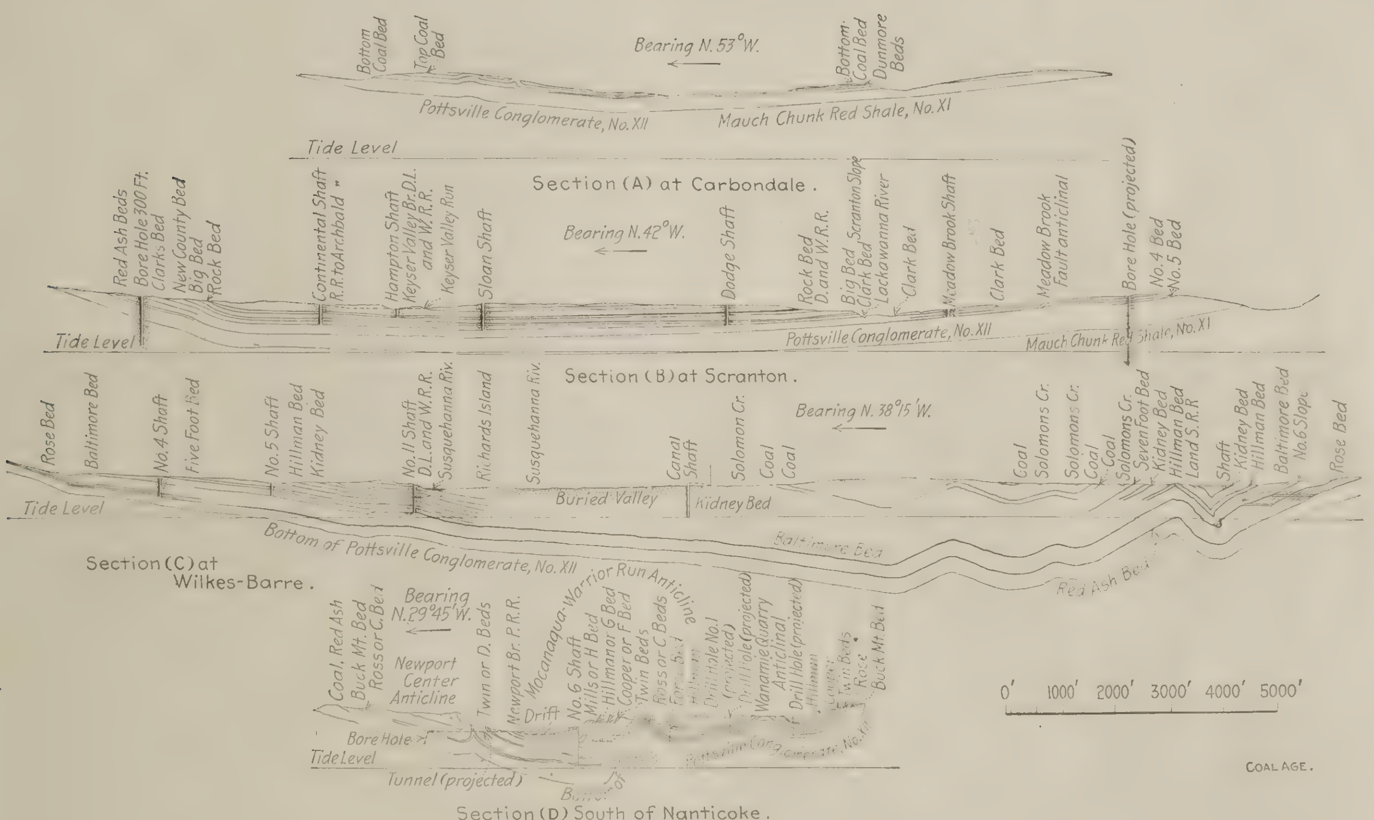
In the early mining in this field, as has been stated before, the developments were made in the middle series of coal beds, which in the vicinity of Scranton are known in descending sequence as the Diamond, Rock, Big or 14 ft., New County and Clark. These seams can be identified on the cross-sections accompanying this article, from which it will be noted that the names by which they are designated differ both east and west of Scranton. At Wilkes Barre the Big Seam is known as the Baltimore, while at Olyphant and eastward to Forest City, it is known as the Grassy Island. It very frequently happened in mining this and other beds of coal, in the earlier years of the industry, that but one or two benches of the seam were considered marketable, and consequently the other benches were either left in place, or broken up and thrown into the gobs. This resulted in the loss of a large quantity of coal much of which has not, up to the present time, been recovered. In addition to this great waste, care was not exercised to lay off the mine workings so as to bring pillars in lower beds under pillars in the bed immediately overlying. The result of this failure being extensive squeezes that have closed up large areas of the mine workings practically destroying the remaining pillar coal.

I have recently had occasion to investigate such a caved-in territory, due to the causes above mentioned, and found that 46 per cent. of the original contents of mineable coal has been almost irretrievably lost.

In recent years, more care has been exercised in the columnization of pillars, and a larger ultimate recovery can reasonably be expected.

One Reason for Unsystematic Methods

One of the principal reasons for the unsystematic methods of mining above mentioned has been that most of the early developments in this field were made by individual operators, holding the properties under comparatively short term leases, which carried burdensome minimum royalties, and thus compelled the operator, in order to retire his capital investment, and make a reasonable profit, during the term of his lease, to take only the cream of the property, oftentimes to the great detriment of the remaining mineral. During the past 20 years most of the individual operations throughout the anthracite regions have come into the possession of the 8 railway corporations, engaged in the transportation of anthracite to market. These companies have



Cross-sections of Northern Anthracite Field

generally adopted more scientific and systematic methods of mining, and consequently greatly reduced the waste from the causes mentioned.

Notwithstanding these decided improvements in methods, I am firmly of the belief that there are many places in the northern anthracite field in the thin beds of coal, by which is meant beds of 4 ft. and less in thickness, where decided economy in development and operation and in ultimate yield could be effected, by the adoption of the longwall system of mining. Strange as it may appear, when it is remembered that the anthracite fields of Pennsylvania were largely developed by men of experience from the British Isles, where longwall mining is the common and accepted practice, there have been very few instances and none of any marked success, of the introduction of this system in anthracite mining. It is true that the attempt has been made at various places, but so far as I can learn, it has never been systematically and persistently adhered to. Instead of this, to a very large extent, the methods that were adopted many years ago for mining beds of 5 ft. thick and upward, have with few modifications been continued in the thinner seams, in many cases even using the same old-style high mine car, which necessitates the removal of from 12 to 24 in. of roof or bottom rock, in *all openings*, to make hight for cars and mules. This, of course, means excessive cost of mining, and in my opinion, the system must be radically changed in the very near future, as it is only tolerated now because of the fact that at most of the going operations there is still some coal in the thicker seams which serves to "sweeten up" the average cost.

Underground Haulage

Underground transportation methods in the anthracite field have not been as completely revolutionized as has been the case in most of the bituminous regions. While it is true that most of the large anthracite companies have, in recent years, installed compressed air and electric haulage to a very considerable extent on the main roads, they still almost universally depend on animal power for handling mine cars in rooms. The use of gathering locomotives, electrically operated, has long ago passed the experimental stage, in the bituminous field, and in my opinion, would be adaptable in many of the comparatively flat seams in the northern anthracite field. Based upon experience with this method of transportation, in the bituminous field, I believe the average transportation cost in the comparatively flat workings in the anthracite field could be greatly reduced by the introduction of properly designed electric gathering locomotives.

Space will not permit of going into detail on the criticisms here made, but I am quite convinced that anthracite managers would find it beneficial to investigate more carefully methods of mining and transportation that have been found economical in thin bituminous beds of coal.

The enormous increase in the amount of coal produced by mining machines in the bituminous fields in recent years, showing the steady improvement in apparatus and methods, together with personal experience in the operation of mining machines in bituminous coal, convince me that by such modifications as local conditions may dictate, this system of mining coal could be profitably adopted at many places in the northern anthracite field. I have recently been privileged to see a mining machine of the semi-longwall type in service at one of the mines in the northern anthracite field. This machine has been in operation for several months, and has proved a mechanical success, but as its operation is still in the experimental stage, the commercial results cannot at present be quoted.

I am informed that experimental work with similar mining machines is now in progress at other operations, but the results are not in my possession. This experimental work will probably be continued, as it is in the hands of capable and farsighted managers, who will doubtless carry the experiment to the ultimate outcome, and inform themselves as to the most suitable methods as developed elsewhere.

Second Mining of Rejected Bottom Bench Coal

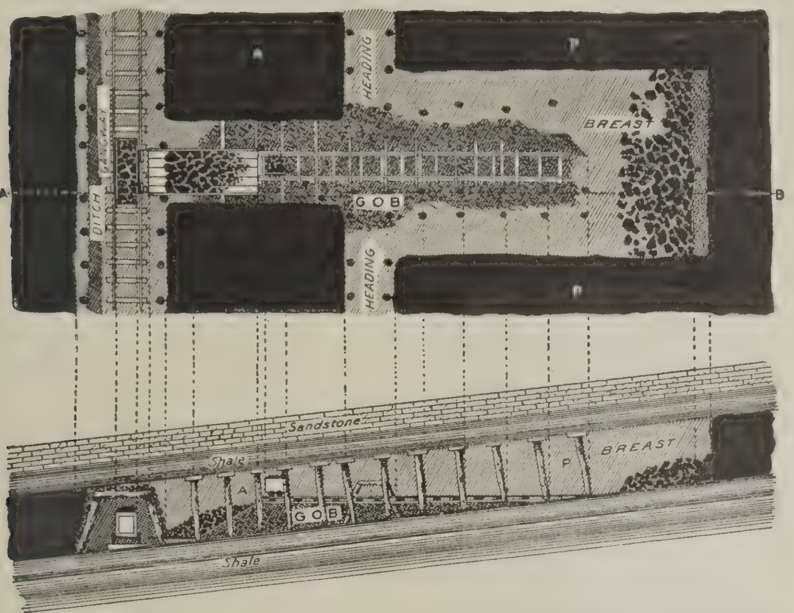
Preparation of Anthracite Coal

The preparation of anthracite coal for market is practically a manufacturing business that has been the growth of years of experience. It is a well known fact that to get the best results out of anthracite coal, in the furnace, it must be of uniform size. In the earlier days of the industry, it was believed that only large-sized coal, commercially known as lump, steamboat, broken, egg, stove and chestnut coal could be successfully burned. In consequence of which coal smaller than chestnut, which was made over 5/8-in. square mesh, was discarded and deposited on waste banks. In recent years, methods of firing have been so improved, that coal as small as that passing over 3/32-in. round mesh, can be successfully burned.

During the past 15 years a very large part of the culm banks in the anthracite

field have been rehandled and the coal smaller than chestnut marketed, until, at the present time, there is a comparatively small amount of such culm-bank material unused.

The sizes of coal larger than chestnut are commonly known as domestic sizes, and smaller than chestnut, as steam sizes. Domestic coal is sold at very much higher prices than steam coal, therefore the important matter for the manager to consider is the production of the maximum quantity of domestic sizes. Within recent years, great improvements have been made in this particular, by the proper design and arrangement of the rolls and other machinery, in the breakers, where the coal is prepared. This question of preparation of anthracite coal has been very well covered recently in a paper read before the American Institute of Mining Engineers, in June, last, at the WilkesBarre meeting, by Paul Sterling, chief mechanical engineer of the Lehigh Valley Coal Company, in which he quite fully described the new breaker recently constructed by that company, at Mineral Spring colliery. The yield of domestic sizes at that breaker is large.



Buggy Breast, Anthracite Region. On a 10- to 18-deg. Pitch

Comparing the Efficiency of Plants

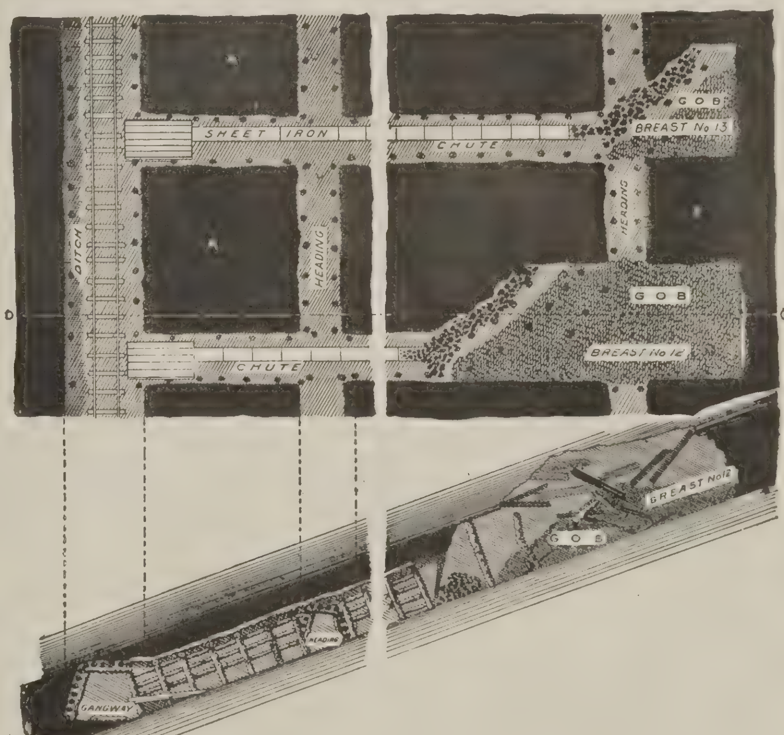
It has been the usual custom to compare the yield of anthracite-coal breakers on a basis of the percentage of domestic sizes produced. A proportion of 65 per cent. of total output of breaker in prepared sizes is regarded as good practice. This method of comparing the efficiency of plants and of their management is misleading, for it may be possible that a particular breaker is not recovering the maximum amount of small coal, viz: Coal below the size of chestnut. In such a case, the *percentage* of prepared sizes would naturally be high, and the operator would perhaps delude himself with the belief that he was accomplishing good results, when, as a matter of fact, his plant might be losing many tons of recoverable small coal.

The unreliability of the percentage method of determining results was forcibly brought to my attention some years ago, when in charge of 10 or 12 anthracite plants in the Wyoming valley, and a method of calculating and comparing percentages was devised which has since been adopted, and I believe it is the only true method of making comparisons. This was to determine at each breaker the yield in gross tons of each size per 100 cu.ft. of run-of-mine coal going into the breaker. On this basis, I have recently found breakers producing as low as 1.50 gross tons of prepared or domestic sizes, and others producing as much as 2.10 tons of prepared coal. In both of these cases, the character of the raw coal going into the breaker was about the same. The great disparity in results was entirely due to the manner in which the coal was handled in the breaker.

In comparing the final results in the production of anthracite and bituminous coal, it should always be remembered that while approximately 95 per cent. of the bituminous coal loaded into the mine car is a marketable product at practically full market value, anthracite coal, on account of the preparation necessary to make it marketable, is subjected to a loss in breakage, and degradation of sizes, which amounts to about 25 per cent. of the raw material loaded into the mine car at the face, in the northern anthracite field, and in the southern field the loss is frequently much greater.

Before leaving the northern anthracite field I think it desirable to mention more in detail the mining practices and conditions which result in great loss of high-grade fuel annually.

While it is well known in the anthracite fields, it may not be realized elsewhere that nearly all anthracite coal is mined by shooting it off the solid. This method was doubtless the best in the early days, and the results attained were reasonably good, when experienced coal miners were employed, but it is a well known fact that for the past 20 odd years, the proportion of such trained miners has steadily decreased, and their



Sheet-iron Chute Breast, Having a Pitch of from 18 to 30 Degrees

places have been taken by men from the southern and central countries of Europe, who have had no training whatever in the mining of coal. On account of these inexperienced men being unable to understand the English language, it is very difficult to educate them into competent coal miners; consequently many of them only learn how to drill holes in the coal, put in an excessive quantity of powder, and blow the coal into culm or slack, throwing large quantities of it into the gob, where it is lost. The percentage of waste by this method of mining is greater in the thin beds of coal by reason of their being generally of a harder nature than beds of greater thickness.

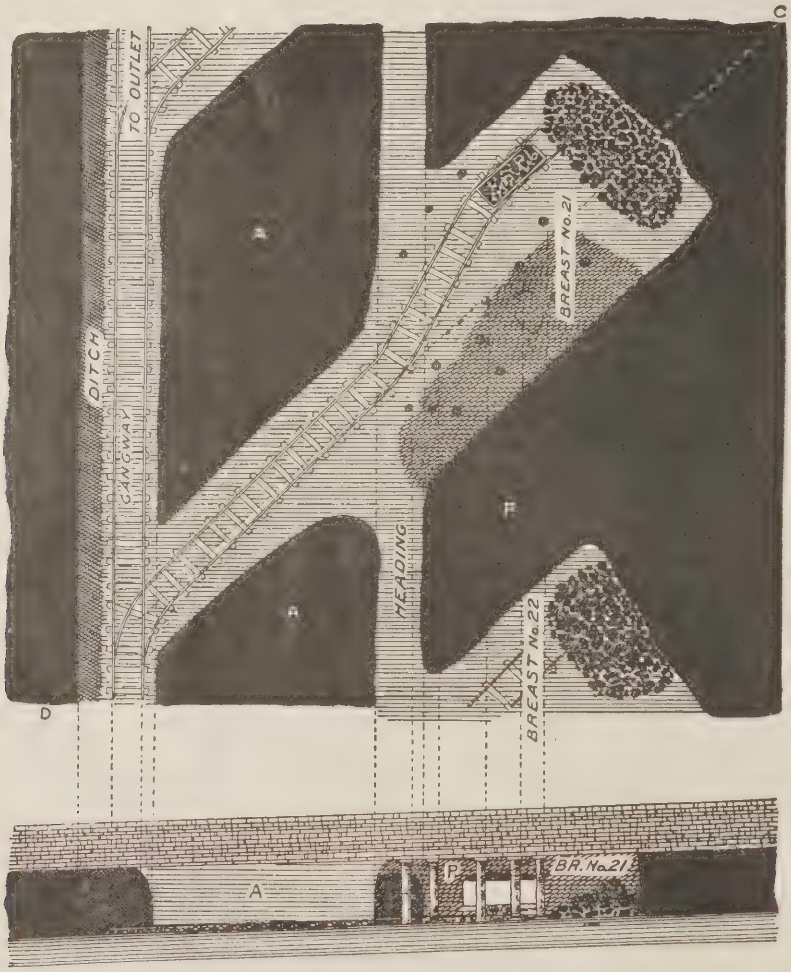
While the employment of such large numbers of inexperienced miners from the European countries mentioned (about 65 per cent. of all of the employees in the anthracite field), results in considerable waste of good coal, it must not be inferred that these men are generally incompetent, as it has been my observation that very many of them learn quickly and make most excellent miners when properly instructed by English-speaking men of ability, tact and patience. It has further been my observation that the Hungarians, Poles and other men from Central Europe who, when they come here, are generally young and vigorous, rapidly become Americanized.

A Source of Waste

Another source of very great waste of good fuel has been referred to before, but it will bear repetition. In the early days of marketing anthracite coal, it was thought that only the bright, lustrous, glassy coal could be successfully burned, and the public was educated to that belief. As is well known, nearly every bed of coal carries one or more benches of what might be termed "second-grade" fuel, commonly designated as "bone." The operator and the miner are expected to discard practically all of this material, very large quantities of which will analyze between 65 and 75 per cent. of fixed carbon. In order to compel the miner to discard this "off-color" coal, he is regularly docked if any noticeable quantity appears in his mine car when it is dumped into the breaker. Therefore, in self-protection, he must throw into the gob anything that appears to him to be doubtful. The large quantity of good coal which is thus irretrievably lost can hardly be conceived. A noticeable instance of this wastefulness, which is forced upon the coal operator by unreasonable market demands, is the treatment of a bench of coal in the Red-Ash bed, in the vicinity of Wilkes-Barre, which is known as Blue Coal. This bench varies in thickness from 18 in. to 3 ft., and as will be indicated by its designation, the only thing wrong with it is that it lacks luster. The major part of this bench of coal will analyze in fixed carbon very close to the average of the balance of the Red-Ash bed, but almost entirely on account of its appearance, it has for years been rejected.

I would recapitulate the causes of serious loss in the mining of anthracite coal in this region by reason of which over 40 per cent. of the original content in the ground is lost as follows:

1. Inadequate and improper pillar distribution.
2. Obsolete and wasteful methods of breaking down the coal.
3. Rejection of Blue Coal and good bone, and
4. Excessive and unnecessary breakage of the coal in course of preparation.



Wagon Breast, Anthracite Region, Under 10 Deg. of Pitch

Governmental Insurance

The Miner's Relief Bill of Maryland provides for the assessment of 27c. per month on each operator for each employee engaged directly in or about the mines, and a like assessment on the wages of each employee. The tax on the operator is believed sufficient to pay the dependents of an employee, who is killed, $1500. The tax on the workman is expected to pay him a dollar a day for one year, or during disablement if he is not disabled for so long a time; $750 in case of loss of both hands or both feet, or one foot and one hand or loss of sight of both eyes; $375 is paid for loss of either hand, foot or eye, together with $1 per day for 26 weeks (Sundays excepted). The benefits are secured by application to the County Commissioners. If a release is accepted, the applicant waives the right to sue the operator on account of injury or death.

Car Oiling

Where cars are oiled at the foot of a shaft or slope, care should be taken to have the waste oil drained to a tank. The oil should be of high-flash point and it should flow with freedom at the temperature at which the oiling has to be performed. These are the general requirements of good practice anywhere, but they are peculiarly pertinent below ground. Had care been taken at Pittsburgh, Kan., to follow these rules, it would not have been necessary to heat the oil by putting heated car wheels within it with unfortunate results. All of which leads to the conclusion that in winter it is impossible to safely oil cars in the intake of a shaft or slope with ordinary winter oil.

High Humidity for Mine Ventilation

By Frank Haas *

The saturation of a mine atmosphere with steam is not for the purpose of furnishing the water for wetting the mine, but is done to prevent evaporation of water naturally in the workings. In shallow mines, high humidity does not injure the men.

Humidity to the average person conveys a rather vague impression of the condition of the atmosphere. It is understood that this condition follows certain laws involving pressure and temperature and some physical characteristics of both air and water, but still the matter is considered of insignificant importance, and is left to the weather-bureau man who interprets with hazard his observation, and predicts with fair accuracy, but still imperfect results, the succeeding weather conditions.

At least so it has appeared to the mining man, and until recently, the humidity of the mine atmosphere was far from being a matter receiving his consideration. The air-compressor man has run into difficulties in the compression and transmission of air which have been charged to the humidity of the atmosphere, but so far has found no practical remedy. On the other hand, the iron metallurgists have, after a careful study of its effects, devised a method by which remarkable economies in the fuel consumption of iron manufacture are accomplished.

The mining man has, in recent years, been compelled by law to keep his mine wet in order to keep down the coal dust, which, when dry and in suspension, is considered dangerous, not only as a means of propagating, but even of starting an explosion. He has found in attempting to comply consistently with the mining laws, in so far as keeping all parts of his mine wet by the sprinkling method, that he has undertaken an impracticable proposition. A study of the atmospheric conditions of his mines will plainly show him why his efforts are futile and also show him the remedy. It is by no means an unusual condition of the atmosphere by which 15,000 or even 20,000 gal. of water may be exhausted from the average mine with normal ventilation in a day's time. It would be a difficult task indeed to transport and uniformly distribute such a quantity of water in each period of 24 hours.

Spray of Water Is Inefficient

Passing a current of air over a body of standing water will not saturate the air even though it is carried over a considerable distance. Introducing a spray of water into an air current does not accomplish the result, nor can it be accomplished in this manner unless a large number of sprays are used with a large waste of water. This method, at best, would be imperfect and if carried out to the extent of actual practical value would be quite expensive. The reason for its inefficiency is probably due to the fact that the air does not have sufficient time, in its contact with the water, to saturate itself, and the water, applied in comparatively large particles, is not maintained in the air current, but promptly drops to the floor where it remains worthless for the purpose.

The general laws governing the humidity of the atmosphere have been thoroughly worked out and the United States Weather Bureau has supplied us with tables showing the quantity of water for each per cent. of humidity for various temperatures and pressures. We have yet to learn, however, the rate at which the atmosphere becomes saturated, which involves both time and surface exposure. It is not unreasonable to suppose that the rate at which water vapor is disseminated would be proportional to the area of water exposed, although theoretically vapor tension is dependent entirely on pressure and temperature and independent of the medium.

It was with some surprise that it was found, while investigating the humidity of the atmosphere, that even during the time of heavy and continuous rain, the air was still far from saturated and the humidity well below the one hundred per cent. mark. This indicated what had previously been experienced along other lines; that it was no simple matter to raise air and hold it at the saturation point.

If the theory, held by many competent mining engineers, that a wet mine is safer against danger from a coal-dust explosion, either initial or in propagation is true, then humidity becomes a most important factor in maintaining the moist condition which the theory demands. In a previous paper[1] has been shown the large quantity of water which is extracted from a mine in winter months, and the dry conditon of the dust can be surmised under such natural conditions as are prevalent during most of the months of the year.

Saturating a Mine Atmosphere Prevents Evaporation.

The object of saturating a mine atmosphere with water vapor is not for the purpose of furnishing the water for wetting the mine, as is sometimes supposed, but for the purpose of preventing the evaporation of such water as is naturally there, or such water as has artificially been supplied. Theoretically, a place in the mine once thoroughly wetted and ventilated with a saturated atmosphere, will remain wet indefinitely. This then is the condition which should be attained.

The most favorable conditions for bringing air to the saturation point would be to have the water in the most minute particles and exposed to the air for a considerable length of time. The finer the particles, the greater surface of water exposed to the air. This is probably the most important factor, and if the particles are sufficiently small, they will be suspended in the air current and this will give the time exposure necessary. This favorable condition of water is exhibited when it is in the state of a fog, and it has been found that the saturation of air is both rapid and complete under these conditions.

To produce a fog in an atmosphere, it is necessary to lower the temperature of the air below the dew point or below the temperature at which the quantity of water vapor originally held will more than saturate it. The excess vapor will be changed to water in very finely divided particles. No practical method can be evolved from this, however, as temperature, as well as water vapor must be maintained and the outside air, when humidity is most desired, is both deficient in temperature and moisture; furthermore, the changing of the temperature of large volumes of air in a short interval of time is quite a difficult task. The simplest method is to disregard temperature and introduce an excess of moisture into the air by means of steam. The results attained are independent of its temperature, or pressure provided a sufficient quantity is introduced.

Temperature, as has been previously mentioned, is one of the important factors governing humidity. In winter time the temperature of the air entering the mine is usually lower than that normal to the workings, and even should such air be saturated when it enters the mine, it would still be greatly deficient in moisture when it reached the remoter workings. The temperature of a mine of considerable

*Consulting engineer, Consolidation Coal Company, Fairmont, W. Va.

[1] *Bulletin* No. 425, U. S. Geol. Surv., "Explosibility of Coal Dust."

development is fairly constant throughout and fluctuates but little during the seasons of the year. The air which is forced through the mine by the ventilating system rapidly conforms to the mine temperature, rising to this temperature in winter and dropping to it in summer.

The distance from the mine mouth to a point where the temperature of the air current is equal to that of the normal mine temperature depends on the heat of the day and the velocity of the current. Under ordinary conditions, this distance will not exceed 2500 ft. It is the first 1500 or 2000 ft. of the mine air current which must be brought up to the normal temperature of the mine atmosphere and constantly saturated to 100 per cent. humidity. The temperature will take care of itself from the radiation of the side walls of the entry and the fog from the steam traveling with the air current will constantly supply the water vapor necessary for saturation by the gradual increase in temperature. If, by this means, the air current carries 100 per cent. humidity at the point where it has reached the normal mine atmosphere, the rest of the mine will be found to contain a saturated air.

The System Requires That a Blowing Fan be Used

The capacity of an air current for carrying fog in suspension is so great, that there is no question of delivering sufficient for all practical demands. In fact in practice it has been found that it was necessary to watch the excess, rather than the deficit of water. Should there be a decided excess, then the fog will continue with the air in its course through the mine. Fog in working places, in manways or haulage roads, is an objectionable feature and should be avoided. This would demand that if steam is introduced into the air current it should be in the air course, where no person is supposed to travel except for inspection or repair purposes. It would further require that a blowing fan be used; the system can be used, however, with an exhaust fan. But it would require other than the ordinary entries for the intake.

When the sprinkling of mines was first agitated as a safety precaution against dust explosions, it was opposed by many with the argument that a wet condition of a mine resulted in the disintegration of the roof with additional fatalities; the roof being the cause of the largest percentage of deaths. These arguments and statements emanated from opinions rather than facts. It is a difficult matter to analyze statistics to the extent of definitely settling a question of this kind and the problem will find supporters on both sides for some time to come. It is a fact, however, that during the time sprinkling has been widely practised in the bituminous mines of this country, no material increase has resulted in the fatalities due to roof falls, nor has there been any noticeable increase in the expense of cleaning up roof rock, which would naturally result if any additional cause for such fall should be introduced.

From a theoretical standpoint, the argument appears rather in favor of wet mines. Most mines are naturally wet and when they are not ventilated the atmosphere in them is at, or near, saturation. Adding moisture to the circulating current or adding water to an artificially dry mine would be simply restoring the natural conditions, and by maintaining such conditions the disintegration of the roof should really be lessened. It is reasonable to believe that non-uniformity of conditions, notably of temperature and humidity, would have a more harmful effect than conditions made uniform by artificial means.

High Humidity Not Injurious to Men

It has many times been stated, mostly from theoretical grounds, that a saturated mine atmosphere is detrimental to the health of the coal miner and his capacity to do work. Whatever may be the conclusions based on the results of comparatively high temperatures (85 to 92 deg.) which are encountered in some of the deeper mines of Europe, we can affirm that in the bituminous mines of West Virginia, where the temperature will average about 60 deg. F. the year round, there has been absolutely no complaint from miners either as regards health or the ability to do work. It is probable that when higher temperatures are encountered the physiological effect of depression and fatigue will result from a saturated atmosphere, and under such conditions and results the method of atmospheric saturation would not be recommended, but as no such conditions, or if any, comparatively few, exist in this country, it can, therefore, be used to great advantage as a safety precaution.

During the past year two explosions have occurred in the Fairmont region of West Virginia. The coal mined in this region is highly volatile and is considered capable of making a dangerous dust. Both of these explosions were solely from firedamp, and arose from a sudden inflow of natural gas from a defective gas well situated in the vicinity. Both explosions were violent, doing considerable damage to improvements inside the mine. The extent of the explosions was localized to the part of the mine where there was an explosive mixture of gas and did not extend, or propagate beyond it. The conditions were favorable for a disastrous dust explosion and the reason that the explosion did not extend over the entire mines, or in fact over several connected mines, was attributed to the wet conditions therein and to the fact that the air had been kept saturated for some time previous. This is perhaps the best argument that has yet come under our observation and has increased our faith in wet mines as a preventative of coal-dust explosions.

Immediate Action after a Colliery Disaster

In summarizing the immediate action a manager should take in case of a colliery explosion, or other disaster, W. E. Garforth, English authority on rescue work and the recovery of coal mines, said:

"Telephone for the mine inspectors and government engineers at once. Send a motor car if they are within distance. Communicate with all emergency officials, and members of the rescue team, not in the mine; impress on them the necessity for coolness. Send for the colliery doctor and laboring medical men. Confer with the leader of the rescue party and the chief of the ambulance corps as to the appointment of members to descend with the first exploration party.

"If the hoisting appliances are disarranged, provide means of descending into the mine. If the fan drift is damaged, arrange for its immediate temporary repair. Boards overlaid with brattice cloth, or with strips of the same, are sufficient in the early stages of exploration work. Consider the advisability of using a steam jet in the upcast shaft, or of causing a downward current of air in the downcast shaft, by means of a waterfall.

A matter of great importance is to decide whether, in case of a fire, the fan should be kept running. This problem must be solved by the manager himself, as no general rule can be given; a definite knowledge of the special conditions is necessary to a correct solution. If the fan be kept running, the smoke will be drawn through the workings and imprisoned men run a greater risk of being suffocated; on the other hand, if the fan be stopped, firedamp may accumulate in the workings, or abandoned parts of the mine may give off unexpected quantities of gas, and cause a further disaster. I may say, however, that experience in past accidents indicates that the course to be pursued seems in favor of stopping the fan for a limited period, while an exploration is attempted.

The underground development of every mine should be so planned that convenient and safe locations are provided for the erection of fire dams in case of necessity. At least 30 ft. of narrow entry is necessary for the location of a substantial dam. Recently at one mine, where a strong fire was raging, it was found necessary to build a stopping 28 ft. in length. This wall consisted of alternate sections of firebrick, concrete and dirt.

Importance of Geology in Coal Mining

By I. C. White*

Geology essential to a proper solution of many engineering problems. Construction and maintenance cost of mine workings can be reduced by due consideration of geologic indications.

Geology, though one of the youngest of the sciences, is nevertheless one of the most useful. Neither the civil nor the mining engineer is properly equipped to grasp and successfully solve the many problems that are sure to confront him unless he possesses a practical knowledge of its laws and principles. This fact we may see strikingly illustrated along the routes of any of our great railway lines, in their cuttings, fills, and tunnels. At one point the engineer has made a deep cut into soft, easily yielding shales at the foot of a steep slope, where his track will long afterward be troubled with land slides which a knowledge of the character of rocks would have enabled him to avoid at only a tithe of the ultimate expense involved. At another point his line has been constructed over loose material near the bank of a river, and his road-bed remains unsafe and unstable, and his re-alinement expense large for years to come.

Again for lack of geologic training a long and expensive tunnel may be injudiciously located, as is the famous one near Alleghany on the Chesapeake & Ohio Railway, at the line between Virginia and West Virginia, where a change in alinement of only 100 ft. southward would have avoided a Pocono sandstone ledge nearly as hard as quartzite through which the tunnel was driven for nearly a mile before the days of dynamite or power drills, at a cost of many thousands more than would have been necessary in the overlying red shale, had the engineer recognized the dip of the rocks and their difference in character.

Geology Essential to Coal Engineer

To the coal-mining engineer especially, is a knowledge of geology essential in the correct determination of the many problems connected with successful mining. He must understand how to trace and keep hold of any particular stratum as a limestone, sandstone or other coal bed which may overlie the one he intends to mine, in order to determine quickly and cheaply the "lay" or structure of the strata in the tract to be operated, before definitely locating his entries or shafts. Otherwise he will incur a constant unnecessary expense in disposing of the mine water and assembling the products of the mine. Then, too, in mountainous regions, where one cannot follow readily the crop of any particular coal bed, owing to irregular or rapid dips, and where the several beds may be held by different parties, he may open the one not owned by the operator, or he may with insufficient knowledge erroneously advise the land owner that the bed he did not sell is being mined by the operator, and thus involve both parties in long and expensive litigation to determine the identity of the coal in question. This is not a conjectural case, but one that actually occurred only recently, and was determined by the Court in favor of the defense in June, 1911, after long and expensive preparation for trial by both parties to the controversy. Had the eminent engineer who advised the plaintiff in this case been sufficiently trained in geology, he would have saved both litigants much time and expense.

This question of the identity of coal beds is one of the most important problems with which the mining engineer has to deal, and unless he has had practical training in geology, the reports that he is often called upon to make on any particular coal property may be misleading. Certain coal beds are fairly regular in thickness and quality, are subject to few "rolls," "wants," or "clay veins," and are of good quality, while other beds in the same series may be characterized by exactly opposite features.

In the New Cumberland region of West Virginia, an eminent mining engineer is reputed to have mistaken the Lower Freeport or "Rogers" seam for the celebrated Pittsburg bed, and embodied this erroneous identification in a report upon a large coal property, while in southern West Virginia another distinguished engineer committed the same error in identifying the Pittsburg coal on a property along the waters of Big Coal river, where the horizon of that particular coal bed was 700 to 800 ft. higher.

In passing from one region to another widely distant in any coalfield, there is always danger of error in the identification of coal beds, especially when the intermediate regions have not been studied in detail. I fell into an error of this kind in my first (1884) study of the coals along the Great Kanawha river through accepting previous identifications by eminent geologists and mining engineers as correct, and thus confusing the greatly expanded Mercer series of coals with those of the Allegheny, until a brother geologist detected the error in a study of the fossil plants.

Rocks Overlying a Coal Bed

The character of the rocks overlying a coal bed will mean nothing to the ordinary engineer, but if he has geological training he will know that a coarse sandstone roof means frequent erosion or thinning away of the coal, and also long and expensive headings to be driven through hard rock, as well as a coal bed generally high in sulphur contents by invasion of sulphur-bearing waters from above. He will also know that a fireclay shale in the immediate roof of his mine will mean frequent and dangerous "falls" and much added expense in entry and mine maintenance. The character of the mine floor, too, will receive his attention, and from its peculiarities he will determine whether it will "heave" or otherwise when subjected to moisture and mine conditions after the overlying coal is removed, and it is called upon to sustain the pressure of hundreds of feet of rock material.

When operating coal beds in a region traversed by faults, a knowledge of the law of faults as illustrated in the classical case of the Yarrow Colliery by De La Beche, or that of the Pahranagat Mountain range, Nevada, by Gilbert, both of which are here republished, will prove of immense value in finding the coal after it suddenly disappears, settling practically always down the slope of the "over-hanging" wall of the fault.

Georges Creek Coalfield, Maryland

By R. Dawson Hall

A semibituminous field of great purity in Northwestern Maryland, where the application of modern methods has not only resulted in a high percentage extraction, but in economy of operation.

The Georges Creek field lies wholly within the synclinal named after that stream. The shape of the field is that of a canoe or spoon, the measures rising along the line of the strike, both northeast toward the Pennsylvania line and southwest toward Piedmont, W. Va., from a center of depression, situated at the pumping station of the Consolidation Coal Company, one-quarter of a mile east of Borden shaft.

This synclinal fold extends beyond Piedmont, W. Va., to the south, running along the northern branch of the Potomac, and this extension is situated partly in West Virginia and partly in Maryland. It exhibits in one place only, and that in insignificant degree, the "Big" or Pittsburgh bed. This lower coal area is not usually regarded as a part of the Georges Creek field, partly because of the absence of the most important beds of that region, and partly because the stream traversing the valley is no longer Georges creek, but the Potomac river. For this reason, this extension will not be treated in this report, the southern boundary line of the field to be discussed being the great bend in the river between Keyser and Bloomington, which completely cuts out all the coal measures, where it breaks through the Allegheny mountains.

To the west of the Georges Creek basin lies the big Savage mountain, and to the east lie Dans and Piney mountains, but whereas the coal-bearing formations extend up the slopes of those flanking elevations, the principal or Big bed is limited to the valley lying between them. The point of highest surface elevation along the basin is at Frostburg. Here is situated the ridge, which divides Georges creek from Jennings run. The direction of the synclinal fold is about N. 37 deg. E., being that generally found in the Appalachian field.

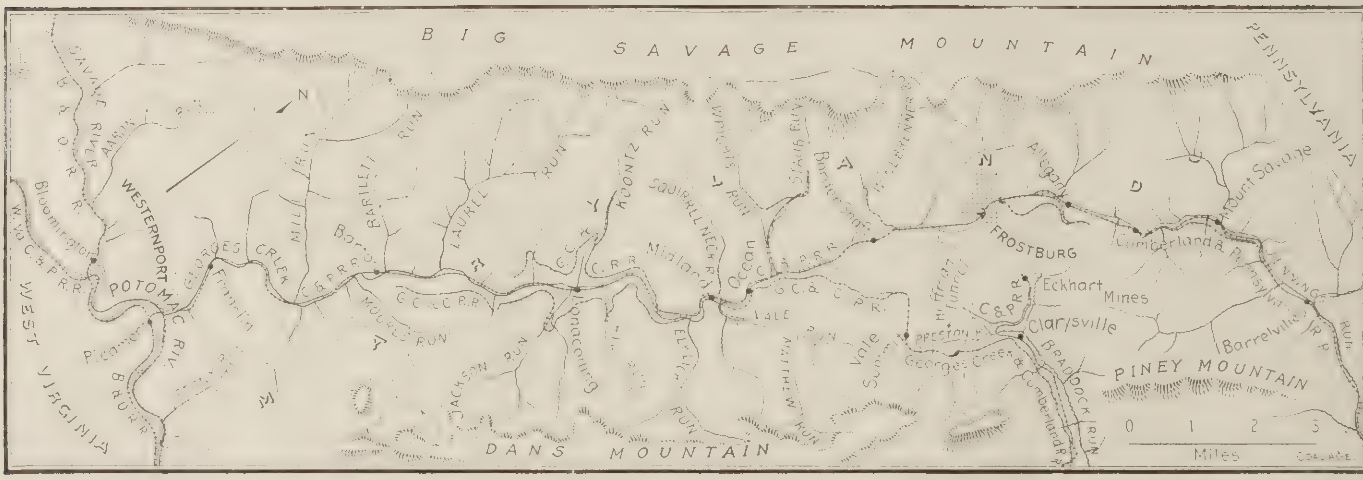
Despite the fact that the edges of the syncline are tilted up to as great an angle as 60 deg., and that the field is situated in the very heart of the Allegheny mountains, where vertical measures are frequently encountered, there are no throw-faults to make working of the measures difficult. On the whole the basin is regular and straight, though minor irregularities occur, which have made much ditching and even some tunnelling necessary in order to connect up the subsidiary basins with the central basin of the field.

Moreover, the coal is not broken, nor markedly prismatic in structure. In this it is very different from the coal in the first bituminous basin of Pennsylvania, which appears to have been more affected by Paleozoic violence. But there are other evidences which point to primeval stress. The cleats of the coal are not strongly marked, the lumps of coal shipped to market being rarely cuboidal. In some places the coal falls so easily that it is mined without shooting, and the roof is everywhere full of seams and tends to shear off shortly rather than to bend before breaking.

Cross-section of Beds

The following cross-section shows all the beds to be found in this field, with the intervals between them; these intervals are not equal throughout the region, and it must be borne in mind that as figured in the table they are merely averages. The Upper Sewickley may be situated anywhere between 95 ft. and 125 ft. above the Pittsburgh bed, the interval gradually increasing toward the south. That statement will serve alone as an indication of the inequality with which beds in this region have been deposited. In the following table, the third column shows the interval between the bed mentioned and the next bed below.

Thus the Dunkard formation contains 7½ ft. of coal; the Monongahela, 26½ to 37½ ft.; the Conemaugh, 24 to 28 ft.; the Allegheny, 21 to 30½ ft., and the Pottsville, 8 ft.; making a total thickness of from 87 to 111½ ft. It will be noted that the Conemaugh, or Lower Unproductive measures, not only contain from 24 to 28 ft. of total coal contents, but also include one bed, the Bakerstown or Barton coal, which is worked at eight separate small operations in this region. It is possible that others may be worked later, and the fecundity of those measures here, and still more further south, well justify the United States Geological Survey in its insistence in the giving of purely place names to measures, rather than names expressive of conditions, which may change their character from region to region.



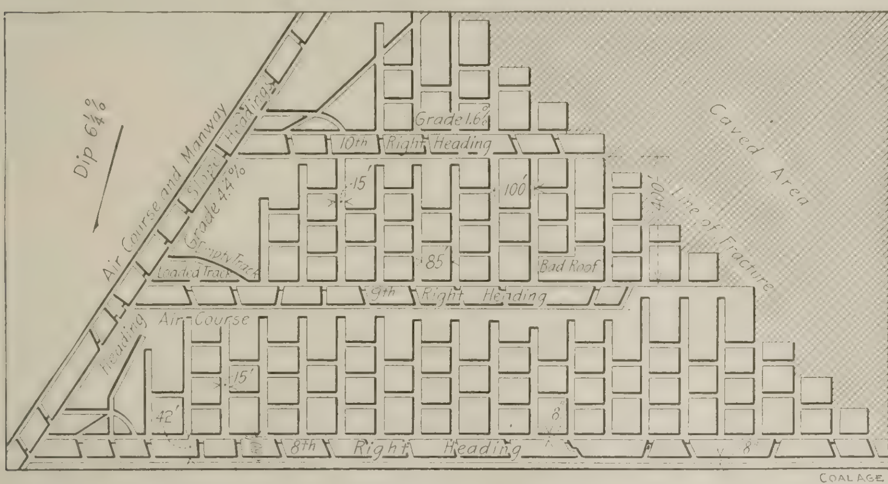
Map of Georges Creek Region, Maryland

Economic Importance of Beds

The importance of the various beds, as at present developed, is best shown by the following statement of tonnage in this field, as produced between May 1, 1910, and the same day 1911, calculated from the annual report, an advance sheet of

which was furnished me by the courtesy of John H. Donahue, State mine inspector of Maryland:

Name of Bed	Long Tons	Percentage of Total Production of Region
Pittsburg	2,921,278	72.7
U. Sewickley	535,340	13.3
L. Kittanning	317,960	7.9
Bakerstown	172,461	4.3
L. Sewickley	26,126	0.7
Clarion	23,982	0.6
Brookville	18,571	0.4
U. Freeport	500	0.1
	4,016,218	100.0



Narrow Rooms, Large Pillars and Retreating System Characterize Mining in Georges Creek Region

It will be seen what a lead the Pittsburgh bed has in this district, and this lead will continue for many years. The Big bed is by no means exhausted, but nearly all the holdings underlaid by this measure belong to the Consolidation Coal Company, and in the coming annual report that company will be shown to have mined 70 per cent. of the whole regional output from that bed. The unworked coal lies in the northern two-thirds of the field. It is 252 ft. deep in the lowest point in the region. This has proved a considerable obstacle in mining and has resulted in slower development where it had to be met. However, a long tunnel, known as the Hoffman, was commenced in 1903 and completed in 1906. Starting in Preston run, a small draft from Braddock run, at a level of 300 ft. below the Pittsburgh bed, and running two miles in a straight line, it taps the basin close to the pumping shaft, which is now only used as a manway and airway, and as a means of delivering power to the workings below. This tunnel, with the aid of subsidiary tunnels and deep ditches, will drain the whole Pittsburgh bed, and the coal deposited over it.

Pittsburgh Bed Not All Mined

The Big, or Pittsburgh bed, which in the basin is about 14 ft. thick, is not mined in its entirety. The upper part is called the "rashings," a coal high in sulphur and interstratified with bone coals and slates. It could be washed with excellent results, but this is never done. The rashings measuring from 3 ft. to 4 ft. and the draw slate below it running about 18 in. are hard to hold in place. When mining is conducted so as to leave them unsupported and to permit the air to work on the draw slate, they fall, and to retain them in place the top coal measuring from 8 in. to 30 in. is left as a protecting plate for the roof. This top coal is equal in value to the breast coal and some day an attempt will doubtless be made to save it in all new workings. Then the rashings will also have to be gobbed or removed. Fortunately the "little rock" above the rashings is a reasonably strong plate, as rocks run in this region. The composition of the Big bed as shipped is as follows:

ANALYSIS OF "BIG" SEAM

Moisture	0.74 per cent.
Volatile matter	18.69 per cent.
Fixed carbon	73.88 per cent.
Ash (including sulphur)	6.69 per cent.
Sulphur	0.81 per cent.
Calorific value	14,191 B.t.u.

It will be observed that the coal is high in fixed carbon and low both in ash and sulphur. This absence of sulphur is perhaps the reason why Georges Creek coal does not spontaneously ignite, however stored, though the causes of such ignition in coal is a much debated subject. It also gives the coal its lead as a smithing fuel, much of it being shipped in box cars and even in sacks. As much as 10 per cent. of it is used for smithing purposes. Some of the coal is sold in Europe, Central and South America, Canada and the far West. It is also used as steam coal for the U. S. Navy.

The Sewickley Beds

The Upper Tyson or Upper Sewickley seam runs as low as the big bed in sulphur and ash and would well take its place in the market though the operating companies are keeping the coal from the two seams separate, having their dumps arranged with a movable baffle plate so that the Sewickley coal may go in one car and the Pittsburgh in another. This is made easier by the hauling of full trips of cars loaded with coal from either bed and by movable display signs notifying the dumpers of the location from which the coal is derived. A method of bookkeeping enables the company to trace their

APPROXIMATE RELATIVE POSITION AND AVERAGE THICKNESS OF THE COAL BEDS OF MARYLAND

Formation	Beds	Average Thickness	Perpendicular Distance
Dunkard Formation	Jollytown	2 ft.	222 ft. 0 in.
	Washington	3½ ft.	48 ft. 6 in.
	Waynesburg "A"	2 ft.	46 ft. 4 in.
Monongahela Formation	Waynesburg or Koontz	3 ft. to 6 ft.	57 ft. 3 in.
	Uniontown	0 ft. to 1 ft.	63 ft. 4 in.
	Upper Sewickley or "Tyson"	3 ft. to 6 ft.	48 ft. 6 in.
	Lower Sewickley or "Tyson"	2 ft. 6 in.	48 ft. 10 in.
	Redstone	4 ft.	33 ft. 0 in.
	Pittsburgh or "Big Bed"	14 ft. to 18 ft.	75 ft. 8 in.
Conemaugh Formation	Little Pittsburgh or "Michaels"	2 ft.	93 ft. 0 in.
	Franklin, Little Clarksburg or "Dirty Ninefoot"	9 ft.	23 ft. 0 in.
	Lonaconing	2 ft.	86 ft. 6 in.
	Elklick	1 ft.	34 ft. 3 in.
	Friendsville	2 ft.	49 ft. 0 in.
	Maynardier	2 ft. to 3 ft.	40 ft. 6 in.
	Bakerstown, "Fourfoot" or "Threefoot"	2 ft. to 5 ft.	97 ft. 3 in.
	Brush Creek	2 ft.	87 ft. 10 in.
	Mahoning	2 ft.	48 ft. 2 in.
Allegheny Formation	Upper Freeport, "Rock Vein," "Threefoot" or "Fourfoot"	3 ft. to 6 ft.	54 ft. 7 in.
	Lower Freeport	2½ ft.	105 ft. 0 in.
	Upper Kittanning	1 ft. to 3½ ft.	45 ft. 10½ in.
	Middle and Lower Kittanning or "Sixfoot"	6 ft.	21 ft. 4 in.
	Split Six	3 ft. to 4 ft.	91 ft. 6 in.
	Clarion or "Railroad" Seam	2½ ft.	13 ft. 7½ in.
	Brookville or "Bluebaugh"	3 ft. to 6 ft.	33 ft. 1½ in.
Pottsville Formation	Upper Mercer, "Mt. Savage" or "Fireclay" bed	3 ft.	10 ft. 10 in.
	Lower Mercer	1 ft.	169 ft. 2 in.
	Quakertown	2 ft.	128 ft. 8 in.
	Upper Sharon	1 ft.	36 ft. 3 in.
	Lower Sharon	1 ft.	4 ft. 0 in.
	Mauch Chunk red shale		

mine cars so that months later any carload of coal can be traced back to the mine, the seam, the heading, and the room in which the coal was loaded and to the men who, together, loaded it. The Consolidated Coal Company used to analyze samples from every carload of Sewickley coal. But finding that the output was very regular, about ten samples are now taken in every mine every two, three or four months, so as to determine the uniformity of the coal shipped. Its excellence can be judged from the average analysis hereunder submitted:

ANALYSIS OF UPPER SEWICKLEY COAL

Moisture	0.63 per cent.
Volatile matter	19.27 per cent.
Fixed carbon	73.88 per cent.
Ash (including sulphur)	6.20 per cent.
Sulphur	0.85 per cent.
Calorific value	14,570 B.t.u

The Lower Sewickley, mined only near the pumping shaft, is markedly like the upper bed, as the average analysis of eight samples shows:

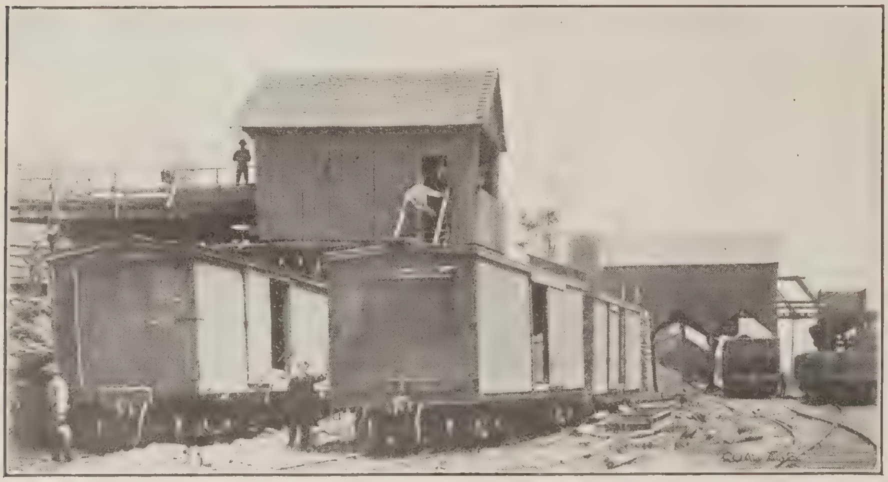
ANALYSIS OF LOWER SEWICKLEY COAL

Moisture	0.66
Volatile matter	18.94
Fixed carbon	73.56
Ash (including sulphur)	6.84
Sulphur	1.14
Calorific value	14,547 B.t.u.

The coals below the Pittsburgh bed mostly run higher in sulphur than the Tyson beds or the Pittsburgh. But for general purposes they are good, having a calorific value of over 13,000 and frequently of over 14,000 British thermal units.

Hauling and Surface Appliances

The equipment of the Georges Creek region has marked individuality. As the mines have dips running from level up to 20 per cent., heavy hoisting equipments are installed. As the coal is thick, it has been possible to introduce heavy draft horses, but mules are also used, the proportion running about one mule to every two horses. There is a disposition to favor horses and even in the Tyson bed, which is thin, the use of stocky ponies is being advocated in place of mules, which, when short, are invariably too light. The horses appear to retain their health under somewhat unfavorable circumstances. The mines are not by any means dry and it has not been possible to avoid the presence of mud in the haulage roads. The live-stock haulage is everywhere subsidiary to that of the rope but in some places electric and compressed-air haulage are used.



Box-car and Gondola Tipples, Exhibiting Simplicity of Construction

In order to put in a safe signaling system, the Consolidation Coal Company has in some places installed engines and dynamos running at an electric pressure of 110 volts. However, a stock of electric batteries is kept in charge in case the signaling dynamo should break down. The fans of the region are large and of slow-speed type, usually arranged for forcing air into the mines, set clear of the shafts or drifts they serve, but connected by fragile ducts, which on an explosion occurring would be blown to pieces, thus saving the fan. However, explosions are not to be expected; the coal is free from gas in the beds worked and there is enough water to keep the dusts from being explosive in character. Moreover, the low percentage of hydrocarbons makes the dusts less explosive.

The tipples are remarkably low and simple. They are not built for screening. No devices guard against the breakage of the coal, which seems to sell without regard to its physical condition. The preparation of the coal is all done within the mine. The excellence of this preparation is evidenced by the absence of any unsightly piles of bone coal along the railroad tracks.

Mining Methods

The Pittsburgh bed is frequently mined without shooting. Black blasting powder is used for almost all coal shots in the Big bed, whereas carbonite is used almost exclusively in the Sewickley and both dynamite and carbonite are employed to dislodge rock.

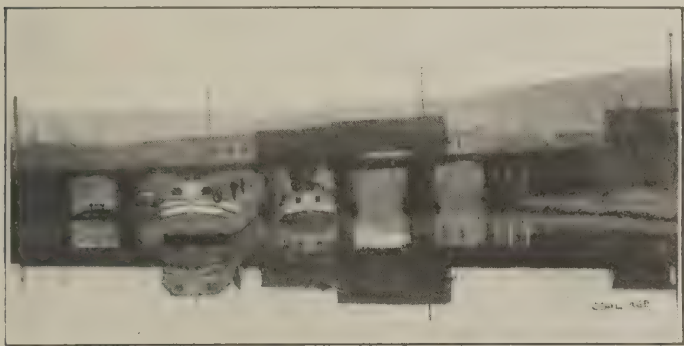
Another interesting feature is to be found in the large quantities of long props used to support the brittle roof. These are 9 or 10 ft. long and measure at least 4½ in. in diameter at the small end, and, if of soft wood, at least 5½ in.; reckoning only, of course, the diameter of the prop beneath the bark. These props are usually stacked on end. They frequently rot where they touch the ground and to protect them they are sometimes dumped indiscriminately and more rarely, laid in crossed piles to dry. They are not usually laid as in other fields after the manner of corded wood, in such a manner that air cannot circulate around them. Corded props rot freely along their full length. As the props cost from 14 to 15c. f.o.b. mine and serve for the extraction of an average of 3.3 tons, the propping of the roof consequently

View at Stable, Showing Excellent Condition of Mixed Stock

consumes no less than 4½c. of the tonnage cost of the coal. In the Tyson bed, long posts are used, being cut to size in the mine as required.

Some attempt has been made by the Consolidation Coal Company to recover salvage rate will be. Some permanent timbering has been creosoted.

There is but little machine digging; only 44 machine-pick diggers and 3 electric chain machines being installed in the whole district. They are used wholly in 100-ft. centers. Roads are laid in the crosscuts. This manner of driving the rooms, together with the absence of gas makes it possible to work several men in a single room, some working at the breast and some in the very lengthy crosscuts

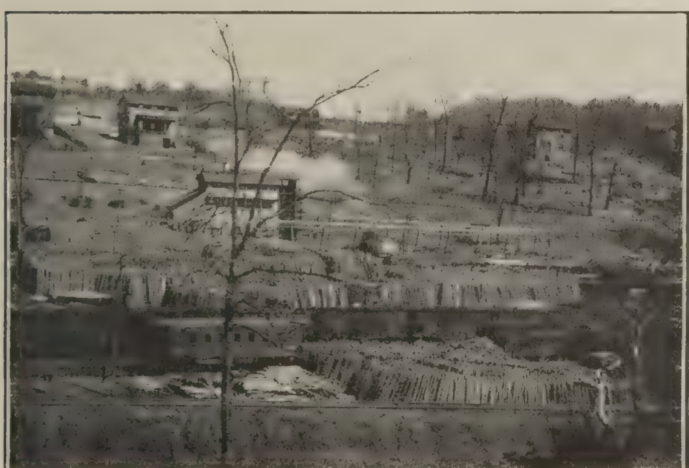


Dumping Coal from the C. & P. R. R. in Barges

Barges Loaded with Coal on Cumberland Canal

Prop Yard in Georges Creek Region

The Roof Being Fissured Demands Much Timber



Props Are, for the Most Part, Shipped In By Rail

The Timber Is Usually Stored on End to Prevent Rotting

the timber used to support chamber roofs, but it cannot be considered successful. Perhaps the proportion recovered does not exceed 8 per cent. The amount drawn from the newly opened Tyson longwall may prove quite large but it is premature to anticipate what the heading and room driving and not in "pillaring" as pillar robbing is here termed.

Rooms Are Quite Narrow

The method of mining now in use is by a series of rooms 15 ft. wide, placed at between the rooms. The nature of the normal projection can be clearly seen in the illustration. It is remarkable that in this—one of the oldest mining sections in the United States—there is the least evidence of the loose-ended wastefulness in operation found in nearly all

coalfields, especially in the older ones. The mines are models of uptodate conservation in a field worked by miners, who brought up to wasteful methods, must have resisted lining up to the more conservative methods of mining.

The Tyson bed is largely worked as subsidiary to the Big bed below, the coal being run to the Big bed track by chutes, either in the mine or outside. These chutes are arranged to have such an excessive fall that storage is provided in them. Thus the coal arrives from the chutes in the large cars used in the Big bed. About 9 per cent. of the coal mined in the Georges Creek region is transported by the South Cumberland canal, to which it is hauled by the Cumberland & Pennsylvania railroad.

Toward the southern part of the field, now almost entirely worked out, long gravity planes were used for lowering loads of coal and raising empty cars. But these have given place to long engine hoists hauling coal out of steeply inclined slopeways to tipples on the level of the outcropping measures, situated on the flanks of the field.

Miners Are a Superior Class

The coal of this field is worked entirely by miners, who are the descendants of the English, Scotch and Welsh miners who immigrated here many years past. It is entirely a nonunion field, but considering the thickness of the coal and the ease with which it is mined the rate of 63c. per long ton is eminently fair. The Consolidation Coal Company has no company houses but owns nearly all the land on which the employees live. Any employee can lease for $2 to $5 a year enough land for a home with a liberal curtilege for truck farming. This lease lasts five years. If the company does not desire to renew the contract, it pays for all improvements at its own price or at a price to be determined by arbitrators chosen by the company and the tenant and by a third arbitrator chosen by the other two. If the tenant is still not satisfied, the terms of the lease permit him to appeal to the county courts. The houses built on this leasing system are not lined up simply in serried rows of uniform plan and color, but are designed and placed to suit the whims of the many owners; they are kept clean and orderly, the tenants delighting in cultivating the pretty flower gardens with which, in nearly every case, the fronts of the houses are graced.

I desire to express my acknowledgments to H. V. Hesse, general manager, and R. A. Walter, chief engineer, of the Consolidation Coal Company, from whom much of this information was derived.

Don't use discharge pipes or water pipes of any kind for air lines if it can be avoided. The scale will block the air ports. If so used, the scale should first be loosened or blown out thoroughly.

Developing a New Field in Iowa

By Carl Scholz.*

Through the construction of a line from Des Moines to Allerton, 68 miles south, the Rock Island Railway is developing the largest unworked coal area in Iowa and what appears from the drilling to be the most compact body of clean coal that ever existed in the State. A conservative estimate indicates that at least 200,000,000 tons of coal, lying less than 400 ft. below the surface, will be available for transportation.

The only reason for delay in this development was the high cost of railroad construction. The new line, in connection with the recent purchase of the St. Paul & Des Moines Railroad by the Rock Island, will result in a considerable coal development near the southern end of the new line. This link will connect the coal mines with a very desirable market on the northern end, where Mason City, with its two cement plants and a number of tile and clay industries, is a large and steady consumer of coal.

One of the important developments in this coalfield has been started by the Consolidated Indiana Coal Company, which holds about 4500 acres of valuable coal land in this field.

Development to Be Finished Next Spring.

The construction on shaft No. 1 has been started, so that the mine development will be complete by the time the rails reach the new properties next spring.

Shaft No. 1 is located about 2 miles south of Dallas or 35 miles south of Des Moines. The mine yard will parallel the main track and will have a capacity of 75 loads and empties. Scales will be provided at both ends of the yard to weigh empties before loading; it is also the intention of the company to weigh the loaded cars before they are switched to the north or south bound track.

The tipple will be of steel, equipped with screens to make four sizes of coal. There is a storage bin of 400-tons capacity, so located as to permit the loading of the smaller sizes of coal from this bin into box cars. A separate box-car loader will be installed for the loading of lump coal.

All buildings will be of steel and fireproof construction. It is now planned to install an electric hoist which will be automatic in operation once the starting lever is put in the proper position. The acceleration, slow down and stop will be entirely automatic, including the dumping operation. While it may seem unusual to provide for electric hoisting at a mine where steam is generated, the saving in wages and fuel, the better control of dumping, and the absence of risk from over-winding justifies the installation of such a plant.

A 500-kw. generator furnishes the power for the hoist and the other motors, including power for haulage and undercutting.

Shaft Lined with Reinforced Concrete Frame

The shaft will be lined with a reinforced concrete frame of a new design on which a patent has been granted. This shaft lining, including the concreting and steel guides, costs about 15 per cent. more than the ordinary wood lining. The shaft has a depth of 175 feet.

The second outlet to the mine is a slope on a pitch of 1 to ¾. It will be timbered with steel beams and divided in the center with an air-tight partition; one side will be used as a travelingway and the other for the airway. Underground workings are planned for a capacity of 2000 tons per day.

A machine shop will be provided for the necessary repairs and a bath-house will enable employees to change their clothing before entering the mine and upon their return to daylight.

On account of the distance from any settlements, the coal company will erect a mining town for the convenience of its employees.

*President, Rock Island Coal Company, La-Salle street station, Chicago, Ill.

Mine Rollers

A rope roller which will not roll is worse than none at all. Where the grade is steep and even, a rope will not wear the ties appreciably when the rollers are omitted. On a 24-per cent. grade, it has been noted that where the grade was even, ties remained intact. But trifling deviations in grade resulted in the grooving of the ties.

If the grade is lower than or conforms to the shape which a rope suspended between the top of the hill and the first car would assume at a normal tension, the rope will not wear on the ties at all. Sometimes it would be well to so adjust a rope-grade. Such a plane would give a quick getaway, and a slackening pull at the end of the run. This, in the case of a gravity plane, is better than an even grade, especially if the change in slope is carefully calculated, so as to make the change regular, with no sudden alteration in grade at any point.

Grades in timber entries should be duly considered. If wood rollers are used, the stalling of a roller while the rope is running may cause a mine fire. The same may be caused by the rope running on a tie. The only safe plan is to arrange that the rope is evenly supported by the ties or the rollers, and iron rollers should be used in every case.

Government Regulation of Coal Prices

By John H. Jones*

It is suggested that much good would result from establishing a maximum and a minimum price at which coal can be sold, and then basing the miner's wages on the selling price. It is also advocated that a law be passed taxing all the coal mines in the United States, so as to provide for the families of miners who are killed.

When we realize that during the past 50 years, the production of coal in the United States has increased from 15,000,000 to 500,000,000 tons, we will wonder how it has been possible to make such phenomenal progress.

There is a saying in the coal business that it is either a "feast or a famine." The coal man is either a prince or a pauper, but taking everything into consideration, say for a period of 10 years, a well managed coal company is able to show a fair average earning capacity.

One bad feature of the industry is, that when there is plenty of money in the business and the prices are abnormal, many inexperienced people start mining coal. This brings about a reaction and extremely low prices.

Coal Profits Have Varied

During the past decade, the profit on a ton of coal has varied all the way from nothing to five dollars. When the prices are high, some coal companies try to make every dollar they can, and get out every pound of coal that can be produced, regardless of the safety of the men employed in the mines. When they are not making money, or, in fact, losing money, it is absolutely impossible for the operator to spend the necessary amount to make his mines as safe as they should be.

A Maximum and a Minimum Price

In view of this situation, would it not be better to have Governmental regulation in the selling price of coal, establishing a maximum and a minimum price at which it could be sold, and basing the miners' wages on the selling price? Make the minimum price of coal high enough to permit the producer of coal to use every means known to prevent accidents and conserve coal.

If it was shown to the buyer of coal that every cent, below a reasonable price paid for coal, was stained with the blood of some poor miner, and thereby robbed the widows and orphans of the proper means of sustenance, as well as the means of educating their children, I do not believe that they would try to break the price, as a certain big railroad did a few months ago by securing their coal for five cents a ton less, which means a loss to the operators of this country of more money than the total amount they receive from this company for coal.

A Law Taxing All Coal Mines

I also believe that a law should be passed, taxing all the coal mines in the United States, which money should be administered for the purpose of paying, to the miner's family, a sum equal to the wages he would receive, in case of his death in or around the mines, or to pay his regular wages, in case of an accident which would prevent him from earning a livelihood thereafter.

There is no more horrible fear, to a miner, than the fear of an accident after he goes down into the mine, and the further fear that his wife and children may be left without means of support, and that his children, in all probability, will not receive the education they should have. This is a serious question and one that should be carefully weighed by all of our legislators.

A Law for the Regulation of the Industry

A proper law for the regulation of the selling of coal, and a proper law for the administration of a fund to take care of the miner, himself, in case of an accident which would disable him, temporarily or permanently, or in case of fatal accident, care for his widow and orphans, will eliminate many of the anxieties of the business, and will do justice to the miners, the operators, and to the public generally.

A New View of the Marianna Tipple and Washer. This Plant Is the Pride of the Pittsburg-Buffalo Coal Company and Is Probably the Most Modern Coal Installation in America. The Equipment and Preliminary Development Work at Marianna Cost More Than $1,000,000

Gas Producer Development

Near Saarbrücken, Germany, there is a gas-producer plant which is operated on mine refuse, containing only 20 per cent. of good coal and averaging over 60 per cent. ash. The fuel used is composed largely of roof slabs from a local bituminous mine.

The generators are of the type known as the Jahns "ring" producer. This producer is characterized by having several combustion chambers, which come successively into operation as gas generators after a preparatory period of gas expulsion and distillation. Furthermore, the arrangement is such that the products of distillation have to pass through large beds of highly incandescent fuel on their way to the gas main, so that the power gas contains only such tar vapors as do not decompose in contact with the glowing coal, and which can therefore be considered as permanent.

Fig. 1 shows a plan and sectional elevation of a "ring" producer having four chambers, each of which can be connected with the main at will. Each chamber is also joined at top and bottom through the passages *B* and *C*, respectively, with the vertical flue *A* at the intersection of the partition walls. The passages *B* and *C* can be opened and closed separately. One or more chambers may be in the gasification stage, and therefore connected with the main, at the same time. The remaining chambers, which are in preparation, discharge through the passages *B* into the flue *A*, and thence through the passages *C* into or under the combustion zone of the producing chambers. Circulation is aided by a steam injector in the upper part of the passage *A*, and the gas is drawn off by means of an exhauster and passed through a scrubber and sawdust cleaner. The gas obtained at the Saarbrücken plant is used under steam boilers and in gas engines. No trouble is experienced with the engines, of which there are about 1800 h.p. in use.

A Producer Burning Lignite

Another form of producer, interesting because of its possible bearing on American needs and development, is the small double-zone suction type in common use through Germany for burning brown-coal briquets. This brown coal closely corresponds to some varieties of American lignite.

A sectional view of such a plant is shown in Fig. 2. The gas is taken off from a point about midway in the hight of the producer and the fire burns from both top and bottom toward the central zone. Air for combustion is admitted through the charging hopper and also through the ash-pit, if necessary. These plants require but little attention beyond filling the hoppers; possibly less than the average producer using anthracite.

A plant of this description is located at Fürstenburg, about a mile from a large brown-coal mine. The coal, which contains approximately 55 per cent. water as it comes from the mine, is ground, dried to a moisture content of 11 to 14 per cent., and briquetted without using a binder. The entire output of the mine is used in this way and the gas obtained drives gas engines for generating electric power.

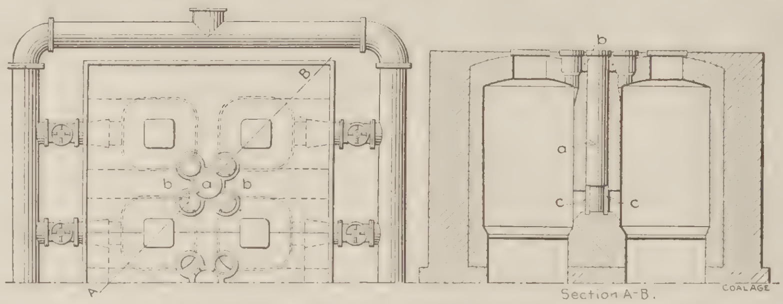

Fig. 1. Plan and Sectional Elevation of "Ring" Producer

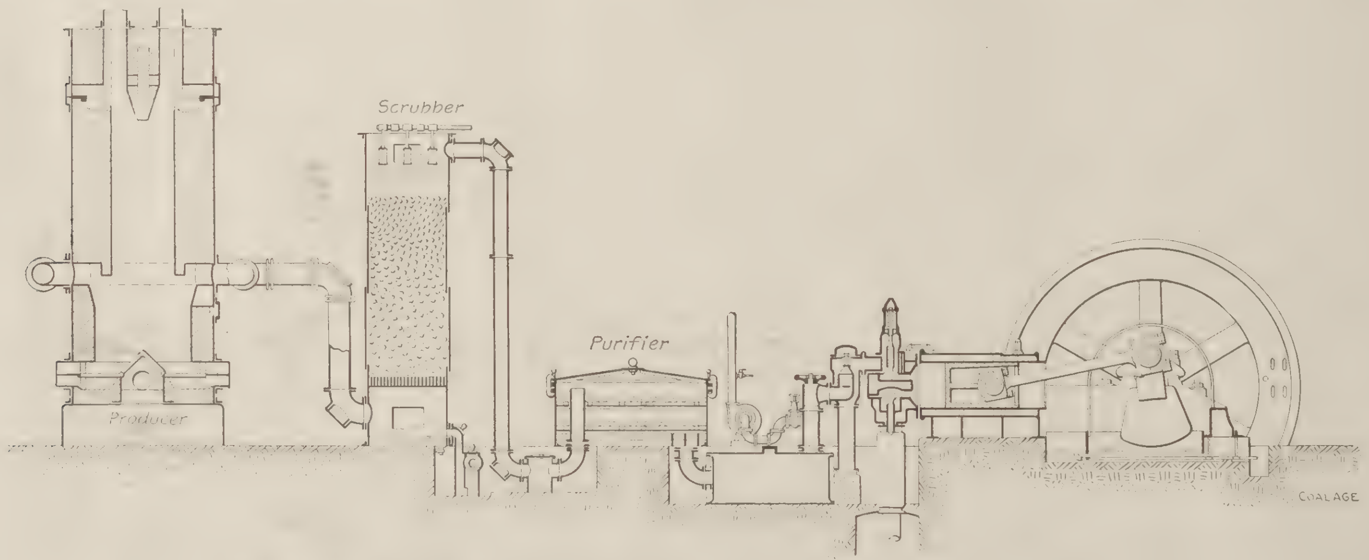

Fig. 2. Showing Sectional View of Double-zone Suction Type of Producer

NOTE—Abstract from Bulletin No. 4 of the U. S. Bureau of Mines, entitled, "Features of Producer Gas Power Plant Development in Europe," by R. H. Fernald.

Painting Mine Survey Stations

The indistinctness with which engineers' centers and bench marks are painted on the roof and ribs in coal mines, would largely be corrected were slaked lime used in place of white lead as a pigment. The lime must be well slaked or it will burn the brush. The objections to lime are the greater weight to be carried and the change of condition, which takes place as it begins to set, often changing a too liquid mixture to one that is too stiff. These are the advantages: A legible mark of an intense white which will last for years, which is scarcely dimmed by smoke, and the use of a material which can be found in almost any plant and which costs but little. Some people prefer to add salt to the water in which the lime is slaked. Whiting does not appear to be preferable to lime. If possible, it would be well to repaint the lime marks after a few minutes' time have elapsed, with the idea of making them more strong and more prominent, but this is not by any means necessary.

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROB'T MCKEAN, Sec'y.

505 Pearl St., New York.
6 Bouverie St., London, E. C.
Unter den Linden 71, Berlin.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this, the first issue of COAL AGE, *we will print* 5000 *copies. No copies will be sent free regularly. There will be no back numbers. The figures which will be shown here each week will represent live, net circulation.*

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

COAL AGE

Looking Ahead

A machine works best after some use when the individual parts fit snug. It is likewise true in the case of COAL AGE—we will give you a broader, better paper as we go along. Do not interpret this as an apology for the present or any early issue, but rather consider it a promise to provide a coal journal that will set its own standards and never be content to measure up by what others have done.

Coal men do not write as often or as much as those engaged in other industries. Our idea is to cultivate your taste along this line, and encourage you to discuss the problems that confront the industry at large. No effort spent in this work will be wasted, for it is one field where you reap in full proportion to what you sow.

There are men who pride themselves on their ability to maintain unbroken silence; they look wise and say, "I never talk!" What would happen if we all followed this same plan? Where did they get their basic information? The laws of gravity, the principles of electricity, and in fact, all science would be "Greek" to them if the great minds of the past had been so indifferent to the advancement of knowledge.

Reverting to this initial issue of COAL AGE and the numbers that are soon to follow, you will observe that practically all of the matter published has been prepared exclusively for us. The first of Mr. Conner's articles, comparing anthracite and bituminous mining methods, is on another page. No engineer in America has had a more extended experience in the two main classes of coal mining, and we are sure that all our readers who follow his remarks will be benefited.

These articles by Mr. Conner form only one series of many that have already been arranged for: Electricity in coal mining; safety precautions; mine explosions; mechanical ventilators; mining machinery; preparation of coal, and various phases of general mining practice are subjects that will be handled immediately in great detail.

Perhaps the most valuable feature of COAL AGE during this first year will be the descriptive articles dealing with operations in each of the important fields in America and Europe. Unless crowded out by something more urgent, one of these articles will appear each week. The first of the series, that published in this initial issue, describes the Georges Creek region in Maryland. This field is one of the oldest in America, and is well suited as a leader. In some instances these general articles will be prepared by members of our editorial staff; however, present arrangements indicate that the greater number of these local descriptions will be written by well known engineers identified with active practice in the particular field described.

We might fill a page here outlining our plans, but we know that you want the realization, not the anticipation. The beginning of your realization is the paper here before you. Much in the way of style and scope has been reserved for the issues immediately succeeding; we want to please you and we have our ears to the ground, listening for any suggestions that you will be kind enough to make.

Reciprocity in Coal

Canada's refusal to sustain the Laurier government in its reciprocity arrangement with the United States must be regarded as the outcome of a complex series of factors. Not only the economic side of the agreement, but also many purely political influences were at work to produce the result. The trade aspects of reciprocity were, therefore, by no means the only ones that led to its defeat. Nevertheless they had their effect, and the coal question was probably as influential as any in turning opinion against the agreement. Particularly in Nova Scotia and the Northwest did this issue figure.

The agreement with Canada provided for the admission of American bituminous coal, such as would not pass through a three-quarter-inch screen, into Canada at 45c. per ton, while Canadian coal, slack or culm, such as would pass

through a half-inch screen was to be admitted to the United States at a 15c. rate. The change proposed was certainly not extreme. The existing rate on American coal entering Canada was only 53c., while imports for last year were about 5,700,000 tons and yielded $3,000,000 of customs duties.

It was estimated that the amount of duties remitted under the arrangement would be only about $450,000. As for the Canadian coal to be admitted to the United States, the change proposed was trifling and would not have altered existing conditions of competitoin largely. Why this moderate alteration in duties on either side should have aroused opposition is not easy to understand, but reference was made to it not only in the sections of Canada which produce coal, but elsewhere.

The real cause of the difficulty appears to have been found in the belief that a change in rates would lead to an alteration in the distribution of freight. Canadian railroad managers were almost morbid in their fear that changes in the tariff would result in diverting the carrying trade from an east and west line into north and south channels, thereby giving business to American shipping on the Great Lakes and the coast as well as to American roads connecting with Canadian points, at the expense of Canadian transportation lines.

In the case of coal, as in that of other commodities, it was apparent that the consuming public of Canada was desirous that the advantages of reciprocity should be realized. The reciprocity arrangement would have tended to cut the rates for coal to some extent at quite a number of points, or at all events would have operated to restrict the control of the market by local dealers. Prices are high in Canada for nearly all consumable goods, and there were many persons who regarded the reciprocity arrangement as essentially a plan to admit cheaper articles from a country where they could be more easily produced.

This was a curious parallel to the similar point of view which existed in many parts of the United States. It is not likely that the reductions made in the agreement either on coal or other articles would have altered prices much, but Canadians saw that the natural tendency of the reciprocity undertaking would have been toward a still freer interchange under the terms of other agreements that might be negotiated later on. "Unrestricted reciprocity," which Sir Wilfred Laurier frankly said had been asked for by the United States on a list of articles including the products of mines, was feared by them as a possibility.

This fear is one that is undoubtedly likely to be warranted by future events. Influenced as it was by the extraneous factors already referred to, the Canadian election cannot be accepted as a truthful indication of Canada's attitude toward closer trade with this country. Canada needs to admit our coal and other mine products at many points along the border at lower tariff rates as much as we need to admit hers.

There is reason to believe that the defeat of reciprocity will prove to have been only a temporary check in the development of trade relations between the two countries, though the election results may defer closer commercial union for a considerable time.

Pollution of Mine Waters

The Health Laws of the State of Pennsylvania expressly exempt the waste from mines and tanneries from restrictive legislation. It has been found on bacteriological examination by the Department of Health of that State that the bacillus typhosus (the bacillus of typhoid), the bacillus anthracis (that of anthrax), and the bacillus coli (the amiable bacillus inhabiting the colon) are destroyed by infusions of mine water. It may be that the presence of hydric and ferric sulphates in the waters of the mining regions of Pennsylvania gives the inhabitants of those regions their recognized relative immunity from consumption.

It is well to recognize that the redness of mine water is not at all due to the presence of sulphuric acid, which is almost colorless. Streams are not, as is often stated, "red with sulphur." The impurity which reddens the creeks and coats the rocks and which has a characteristic ocherous color, is ferric hydrate.

The iron pyrites, in the presence of oxygen and water, break up into ferric hydrate and hydric sulphate. The former is quite harmless; the U. S. Bureau of Agriculture in a recent bulletin terming it a fertilizer. Even unneutralized by earthy oxides, the sulphuric acid is not wholly harmful. Free sulphuric acid, as also free sulphur, has been used as a fertilizing agent and has value when the soil is deficient in such elements. The presence of limestone causes the sulphuric acid to turn to calcium sulphate or gypsum, which is harmless to vegetation. So that in small quantities, as can well be seen, the sulphuric acid and ferric sulphate work no harm to the farmer and are not undesirable components of such river water as is not being used for drinking or washing purposes, and may serve in some quantities to make waters, otherwise dangerous, safe.

And indeed, sulphur is an essential constituent of albumen, to be found in the cells of all plants, and it appears to have been present as part of vegetable life from Paleozoic ages to the present. The extent to which it is so found is not well understood. It is customary in most chemical analyses to heat to desiccation and to treat the elements and compounds driven off before the analysis is taken, as water vapor. In this action, volatile sulphur passes off. Emil Wolff, who has made investigations into the sulphur contained in vegetation, has thrown considerable doubt on the accuracy of his results, by the method of analysis which he employed, because he took no account of sulphur volatilized at low temperatures.

Certain greenish weeds seem to prefer sulphuric waters as a habitat, and all vegetation seems able to sustain life, with a certain percentage of sulphuric acid in the water it imbibes. The water receives a treatment by this infusion of mine waters similar to that frequently employed in purifying plants.

There are places, it is true, where an excess of either sulphuric acid or ferric hydrate appears to have killed vegetation, and where trees have rotted as a result of the injury which has been done to them by its presence. Many trees near mines are killed, by sulphurous fumes, or by the deep burying of their roots in mine refuse. However, some have died and later rotted as a direct result of mine water. On the other hand, the fertility of the banks of the Monongahela, between Clarksburg and Fairmont, W. Va., bears witness to the fact that quite a large amount of mine water does not injure vegetation; otherwise the little grassy islands in polluted portions of the river would not be so universally apparent.

Colliery Notes and Comments

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

A mine fire in the Panther Creek Valley region, Pennsylvania, burned for over fifty years before it was successfully combated.

When an exceptionally high temperature is found at any part of a road through a gob, everything else being in order, and ventilation as usual, look at once for a gob fire.

When laying out a haulageroad see that it is driven as straight as possible. When it is necessary to change the direction, use long radii curves, also connect cross headings with easy curves.

The best and most serviceable form of air bridge is that cut in the solid. The first cost is somewhat high, but experience has shown that this form is best adapted to withstand the force of explosions. It is self-supporting, costs little for repairs and can be easily enlarged at small additional cost.

Experience has shown that one of the greatest aids to power-plant economy is the frequent and systematic analysis of the flue gases given off by the boilers. The quantity of carbon monoxide, oxygen and carbon dioxide tell accurately the quality and quantity of work being done by the boilers and the coal.

Some of the requirements for breaker machinery are: 1. Simplicity of construction, so that experts are not needed to run it. 2. Reliability. 3. Construction with interchangeable parts so that expensive duplicate machinery need not be kept on hand. 4. Rigidity of construction in order to withstand shocks.

Relative humidity means the quantity of moisture in the air as compared with the quantity held in suspension when the air is saturated. This relation is expressed as a percentage. When air is saturated the relative humidity is 100 per cent. Temperature decides the amount of moisture necessary to saturate air.

The new Mineral Spring breaker of the Lehigh Valley Coal Company, at Parsons, Penn., is built entirely of steel, concrete, corrugated iron and glass. The frame is of steel; the foundation of concrete; 1,169,000 lb. of steel were used in its construction. Another unusual feature is its large amount of window area. It has a capacity of 1500 tons of coal per day, and can be operated by 35 men.

If a gob fire is small and easily accessible, dig it out and send it to the surface in iron cars. If too large for such treatment, the gob must be sealed and the fire choked by lack of oxygen. To do this, erect brick stoppings tightly packed with sand. First, build a stopping in the return, and fit it out with a pipe and tap so that the gas may be run off if necessary. Next build the intake stopping, thus sealing the gob tightly and smothering the fire.

When tamping holes for electric firing, take great care not to cut the wire or damage its covering. Allow 8 in. of wire for each connection. Many an otherwise successful shot has been spoiled by carelessness in this direction. See that you have clean wire ends, free from covering, with which to make connections. If they do not seem bright, rub with a knife or stone, then twist firmly. Never loop the wires. Never allow uncovered joints to touch the ground.

Where the object is to obtain as pure a coal as possible, all loading in the mines should be done by hand, as this allows for the removal of most of the impurities at the working face, while chute loading sends out a dirty coal, because everything brought down by the blast is necessarily loaded out. Hand-loaded coal in clean anthracite veins sometimes sizes as high as 2.3 tons per 100 cu.ft. of mine-car capacity, while chute-loaded run-of-mine often runs as low as 1.2 tons.

Investigations made by the Bureau of Mines have shown that the relative humidity of the main-return air current of a mine is nearly always over 90 per cent., no matter what the relative humidity of the outside air may be. The average relative humidity in the returns of various coal mines was found to be 90.5 per cent. A lower humidity was found in the Rocky Mountain region where the air outside the mines is uniformly dry most of the time.

When furnaces are well adapted to the kind of coal to be burned there will be little loss of combustible gas. The efficiency of combustion of the volatile matter in coal depends on the kind of furnace used. With a poor furnace and poor firing an 18 per cent. volatile coal may give results ten or twelve per cent. higher than a 30 per cent. volatile coal. The presence of ash in coal lowers the heating capacity of the combustible by interfering with the circulation of air through the fuel and by loss of heat while fires are being cleaned.

An ordinary miner's lamp will go out in the presence of a small amount of carbon dioxide, if the oxygen of the air is reduced to as low as 17½ per cent. In cases where a mine is sealed up to extinguish a fire, if the sealing is sufficiently tight, the oxygen is soon reduced below this figure; but if the sealing is not tight, the fire may smoulder on, until the opening of the mine brings a fresh supply of oxygen and it then breaks out again. The only reliable data on which to decide the time for opening a sealed mine is that furnished by careful analyses of the mine gases.

To insure the comparatively safe robbing of pillars the following points should be observed: 1. Make all skips as short as possible. 2. Do not allow skips to meet. 3. Keep all skips regular and not too wide. 4. Take out the timbering as soon as possible after the skips are finished. 5. Use an abundance of timbering. 6. Avoid a multiplicity of small pillars or small skips finishing simultaneously. 7. Guard against heavy falls, which are apt to send accumulations of firedamp out into the roadways. 8. Use only safety lamps. 9. Employ only the most experienced and trustworthy men for the drawing of timbers.

The stone-dust method of laying dust in coal mines consists in throwing finely crushed shale dust on the ribs and timbers of passageways and scattering it over the floor. Wherever coal dust is visible, more shale is thrown on. It is also placed on boards fastened to the timbers over roadways, and on swinging canvas shelves. The dust so placed is thrown into the air at each blast and extinguishes the flame. This method is especially recommended for mines where it is not advisable to wet the roof, or in coalfields where water is scarce. The longwall field of northern Illinois, where the floor is composed of shale which is constantly rising and falling in small quantities, thus covering the coal dust, has not had an explosion in 40 years. In Colorado and New Mexico adobe dust and sand are used in place of shale.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Motor Haulage

What weight of motor will be required to haul a trip of ten cars, carrying a load of three tons each up a grade, assuming a coefficient of friction of 0.03 and a coefficient of traction of 0.18, the tangent of the angle of inclination of the track being 0.02619?

ANTHRACITE.

The contents of 10 cars weigh $10 \times 6{,}000$ lb. $=$ 60,000 lb. The 10 empty cars are assumed to weigh 10×2000 lb. $=$ 20,000 lb. The gross weight, therefore, is 80,000 lb. Now the tangent of angle of inclination of track $=$ 0.02619; hence the angle as deduced from the tables is 1 deg. 30 min.

The frictional coefficient is always figured as a percentage of the weight of the body when on a level. When running vertically the friction will be zero because the wheels will not revolve or slide on the track. Intermediately the friction will equal the product of the weight of the body together with the frictional coefficient and the cosine of the slope.

Consequently the frictional resistance of the cars will equal $80{,}000 \times 0.03 \times$ cos. 1 deg. 30 min. Cos. 1 deg. 30 min. equals 0.99966, so that the resistance of the cars equals 2399.2 pounds.

The drawbar pull needed for the elevation of the cars without regard to friction equals the weight of the cars multiplied by sin. 1 deg. 30 min.; or equals $80{,}000 \times 0.02618$ (for sin. 1 deg. 30 min. $=$ 0.02618) $=$ 2094.40 pounds.

But if the motor weighs W lb., being on the same grade, it will have a resistance to downward motion to overcome equal to $W \times$ sin. 1 deg. 30 min. $= W \times 0.02618$ lb. Adding up resistances, we have, $2399.2 + 2094.4 + W \times 0.02618 = 4493.6 + W \times 0.02618$.

We have assumed that the tractional coefficient given is the excess coefficient of traction after allowance has been made for the friction of the motor itself, running on a level. It must be remembered that whatever journal or other friction the motor may have, is taken up by the electrical power and does not effect in any way the tractional ability of the engine so far as adhesion to the rails is concerned. The frictional coefficient of the motor conceived as a tractive engine is but small compared with the whole friction of the motor considered as a power engine and its self-resistance to its own traction is solely a track- and not a track- and journal-resistance as in the case of the cars.

To overcome these resistances there is the friction of the motor on the rails. The coefficient of resistance is reduced in proportion to the cosine of the angle of inclination and is therefore $0.18 \times 0.99966 = 0.17994$; therefore, the tractive pull will equal $0.17994W$. Hence, $0.17994W = 4493.6 + 0.02618W$.

Therefore, $0.15376W = 4493.6$, or $W = 29{,}224$ lb., about $14\frac{1}{2}$ tons.

It would seem that 15 tons would be an amply heavy motor because the tractive coefficient given is low for a sanded mine-rail, and the rolling friction of the equipment is almost twice what it should be, and it is assumed that the weight is being calculated for the maximum grade the motor will have to climb. The tractive coefficient is usually taken at 0.25.

On easy grades it is customary to assume that the frictional and tractional coefficients are unaffected by the grade and that the gravitational resistance equals the weight of the train and motor multiplied by the tangent of track inclination; the sine and tangent for small angles being nearly equal; therefore a short solution for this same problem is as follows:

The frictional resistance of motor and cars weighing in all $80{,}000 + W$, $= (80{,}000 + W) \times 0.03$ lb. The gravitational resistance $= 80{,}000 \times 0.02619$ lb. The traction $= W \times 0.18$ pounds.

Therefore, $W \times 0.18 = (80{,}000 + W) \times 0.03 + 80{,}000 \times 0.02619$.

Therefore, $W \times 0.15 = 4495.2$. $W = 29{,}968$ lb. It will be seen that the short solution for a low-grade serves every practical purpose.

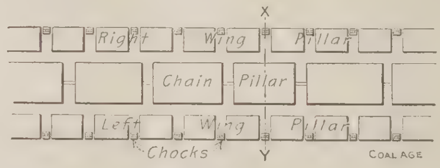
Prevention of Squeeze

If a butt-heading, from which rooms have been driven and the pillars drawn, is under squeeze and it is considered advisable to support the same with chocks, where should these be set, and why?

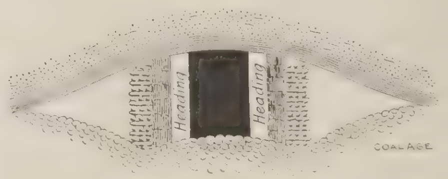
FOREMAN.

The chocks should be placed, as far as is possible, in all the necks of the rooms, over which the squeeze has traveled. They should be placed so that the outer edges of the chocks are flush with the breaking edge of the wing pillar, as in the accompanying figure. There are several reasons for this being a preferred arrangement.

1. There is more movement of the roof and floor and more compression at the breaking edge of the pillar than anywhere else, so that (a) the chock is more surely brought into action (for a chock cannot be driven so tight that it will uphold the roof when it is first put in, and the sustaining strength becomes greater the more the chock is squeezed); (b) the chock is put at a point where it can aid the pillar in the most effectual manner. If the pillar is not thus aided, its edges will be broken; their power for resistance being thus destroyed, the rest of the pillar will be more heavily burdened. The squeeze will move forward from the edge to the heart of the pillar. The placing of the chock should be such as to preserve all the powers of resistance of the coal. A squeeze usually advances by crushing off the edges con-



PROTECTION AGAINST SQUEEZE



CROSS-SECTION ALONG XY

tinuously till the pillar is so much reduced that it can no longer offer an effectual resistance.

2. When the chocks are so disposed, there will be no difficulty in finding an opportunity of building other chocks should they be needed. If set near the heading, further chocking cannot be attempted without removing a portion of the rib.

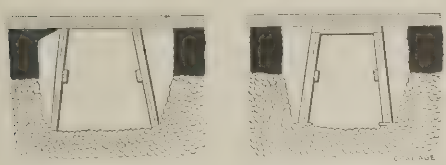
3. The arrangement of chocks shown furnishes an opportunity to inspect the progress of the squeeze, to determine its menace to workings on the advance and to point out the need of further reinforcement.

The accompanying figure shows a section *XY* across the wing and chain pillars in the above plan, with all the dimensions enlarged. The major enlargement of dimensions is in the vertical direction so as to make the curvatures and resultant inequalities of pressure the more manifest.

Post Setting in a Squeezed Heading

It is purposed to place lines of posts along the sides of a heading subjected to squeeze. What precautions should be taken in setting the posts when the underclay is soft? R. F. W.

Ans.—The posts should be set slightly leaning toward the center of the haulway (1 ft. in 12 ft. or 1 ft. in 16 ft.); so that when the underclay is squeezed out from beneath the coal, the post will be forced into a more nearly vertical position. If the squeeze is quite severe, both wing and chain pillars will be affected and the posts should slope toward one another from the opposing sides of the heading. Where this is not attended to, the push of the clay on the post or its flow beneath it, soon loosens it, so that it falls back against the rib. Should the pressure be considerable, the use of a notched cap is to be commended.



Posting in Creeping Headings

Occasions have occurred when all the heading posts, originally set truly vertical, have been upset by reason of an increase in squeeze, so that it was finally necessary to remove them. Inasmuch as such posts are likely to be knocked down by a derailed trip, if set in a haulageway, it is necessary to spike a plank from post to post, at the level of the widest measurement of the car used for carriage of coal or rock. It must be remembered that a squeeze by disturbing the track is liable to make derailments frequent. (See illustration above.)

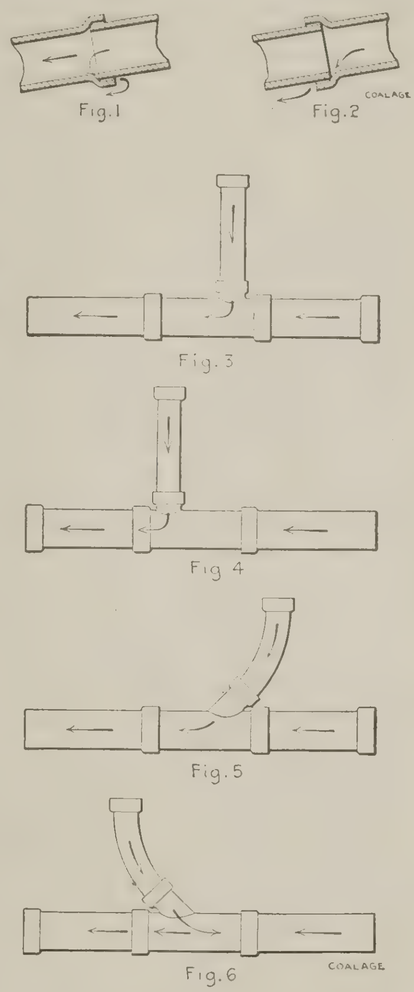
Sewer Pipe Laying

In the laying of sewer pipe, which end of the pipe should be up-grade and why?

M. E. B.

Should there be any leakage at the joints of a sewer line either through the cement-mortar or in the breaks, due to inefficient cementing, or because the sewer has been laid without filling the joints, those leaks will be of least consequence if the bells are turned upward, because the flow of water will not be toward the bell, and the water will have to pass upward to get out of the line. Should any water be passing through the ditch during the laying of the pipe, this water will be apt to wash out the cement if the bells are turned down-grade, favoring the escape of the liquid.

It will be noted that all sewer pipe "specials," wyes, tees, double-wyes, and crosses have bells on the branch lines. These bells would have to be broken off, should it be decided to reverse the accepted method of tile-laying when the branch is being laid. For it can be seen in the illustration, that however the main line may be jointed, the segments of the branch must have their bells uphill unless the first bell is broken off, for it points in that direction. All the wyes have their branches leading away from the bell of the straight line. If the bell on that line is downhill, those wyes must lead uphill, for they lead in the opposite direction to the position of bell on the main. Therefore water traveling in the branch will actually have to enter the main, when a standard wye is used, in the opposite direction to that of the water of the main channel, if the bells are clumsily disposed downhill. Where branches are to be provided, this latter argument is of predominating force, yet it is not likely to occur to the workmen engaged in laying straight pipe till a long string has been mislaid.



Right and Wrong Ways of Laying Tile

Fig. 1 shows a side view or elevation of the correct arrangement of pipe and socket, together with an arrow exhibiting the circuitous route by which water can pass from the pipe to the surface, if the jointing material is faulty or not waterproof.

Fig. 2 is the side view or elevation of an incorrect arrangement of pipe and socket, with an arrow showing how the escape of water from the line is facilitated by the poor judgment shown in laying the line in the manner indicated.

Fig. 3 shows a view from above or plan of a main line and tee branch. The lines are both correctly laid.

Fig. 4 is the plan of a main line wrongly laid and a tee branch leading therefrom. As there is a bell on the branch from the tee, the side line cannot be laid with joints reversed, unless that bell or one on the line pipe of the branch be knocked off.

Fig. 5 shows a plan of the main line and wye branch as they should be laid. It exhibits by means of an arrow how the stream from the branch is compelled to turn to a course inclined 45 deg. to the course of the main current.

Fig. 6 shows what would be the outcome of trying to connect a wye branch to a main line which had been thoughtlessly built with bells reversed. The stream coming down the branch would be obliged (1) to run uphill and (2) would oppose the current flowing in the main line. By slightly tilting the wye so that the branch would slope toward the main pipe, the first fault could be entirely corrected, but for the other there is no such easy cure. The only remedy for that is to use a tee branch or to commence to construct the main line correctly from a point just below the wye onward, arranging the equivalent of two bells on one section of pipe, the lower bell being a artificial sleeve of cement completely surrounding the break in the line, where the two socketless ends of the sections of pipe come together.

Records of Early Coal Mining

That coal was mined in the days of the ancient Britons is proved by the discovery in a Monmouthshire coal mine of one of the flint axes used in those days, and there is documentary evidence extant, showing that in Anglo-Saxon times, about the year 852, an abbot received as part rent, 12 loads of coal, while in 1180 a grant of coal-bearing land was made to a collier in the vicinity of Coundon, Durham county. It is known, too, that coal was burnt in London, to a slight extent, in the fourteenth century because an unsuccessful attempt was made in 1306 to stop its use on the ground that it was injurious to health, and in 1381 it was made an article of trade.

An improvised temporary overcast may be constructed where two roadways cross by hanging brattices and erecting air pipes through which the return air passes.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Reversing Air Current in Fiery Mines

In the course of a paper entitled "An Experiment on the Effects of Reversing a Main Air Current," read before the Institution of Mining Engineers (London), by James Bain and Dr. J. S. Haldane, the authors said the pit selected for the test was Bannockburn No. 3, belonging to the Alloa Coal Company, Limited. Describing at considerable length how the experiment was carried out, they then proceed to discuss the results, and conclude that when the air current is reversed, the air does not travel backward *en bloc*. A great deal of mixing and eddying evidently occurs, with the result that the effects of reversal are spread over a considerable period, so that it takes several hours for the air to attain a steady composition.

This fact is of importance, not only as regards the effects of reversal, but also insofar as it shows that smoke or afterdamp will only gradually attain its maximum concentration when passing through the workings of a mine, and will be but gradually washed out again by a supply of pure air. This, the author says, is of much importance in connection with prospects of rescue and the risks to rescuers in cases of fire or explosion.

In the second place, it appears to them that reversal of the air checks, for the time, the issue of firedamp and blackdamp from the air spaces communicating with the open workings. This is only natural, for, on reversal of the air current, the atmospheric pressure is suddenly increased in all parts of the mine, but more especially in the (normal) return airways.

The difference in pressure is commonly about 6 in. of water-gage, or half an inch of mercury; this will, of course, tend to drive air back into the air spaces connected with the open workings, and check the flow of firedamp, etc., from these air spaces into the roads. It must be understood that this statement refers only to places where exhaust fans are used, as is general in Europe and in the anthracite regions of America.

It would seem, therefore, from the experiments conducted by Messrs. Bain and Haldane, that reversal of the main air current is a considerably less risky operation, even in a fiery mine, than is commonly supposed. In this respect, however, they do not wish to attach too much importance to the single series of observations which they have made. They would rather recommend that opportunities should be taken of making similar trials in other mines provided with arrangements for reversal.

Among the features of interest that an analysis of the air presented, the following are noted:

Excess of carbon dioxide (CO_2) and deficiency of oxygen (O) run parallel with excess of firedamp, in the air after a reversal without the occurrence of an explosion, the percentage deficiency of oxygen being (in the samples taken) about double the percentage of firedamp. If, therefore, owing to any accidental or other cause, the ventilation was so much diminished that the roads became charged with foul air, this air would contain only about 1.5 per cent. of firedamp, when the oxygen fell to 17.5 per cent., at which point lights would cease to burn.

When the firedamp rose to 6 per cent., the oxygen would have fallen to 9 per cent., and seeing that as much as 12 per cent. of oxygen and 6 per cent. of firedamp are the minimum proportions at which even a feeble ignition of firedamp could in any circumstances occur, it seems that, as indicated, the mere slowing of the air current would never produce an explosive atmosphere along the roads. In numerous other mines, whether worked with naked lights or with safety lamps, the conditions are more or less similar.

Manchester, England.

Excessive Splitting of Mine Air

There has been a long continued discussion of the subject of splitting of mine air and it is one which is so important that it deserves all the fervor which has been expended on it. On the one hand, we have mines with few splits, where the air passes from heading to heading, continuously gathering smoke and the foul exhalations from men and mules and lamps till it receives and deserves the expression "soup," which is often applied to it.

In a gaseous mine, such an air current becomes slowly explosive by the presense of firedamp as it travels through the mine, and the further it travels, the more explosive it becomes.

There are strong objections to this system of continuous ventilation. With it, are necessary very high pressures of air, just as high voltages are necessary when electric currents travel in series and not in parallel. All such high pressures involve leakage and make it hard to keep brattices sufficiently tight. It becomes increasingly hard to ventilate such workings and any ventilating system where this method is carried out consistently will eventually break down. Under such a disadvantage, no fan can deliver as much air to the faces as it could where splits were numerous.

High pressures probably increase the violence of an explosion, and the high speeds necessarily adopted make safety lamps less safe, blow out the miners' lights and raise the coal dust. Worst of all, any calamity, as a mine-fire explosion, tends to be fatal in its consequences to those in the workings nearer the point of intake, who might entirely escape if splitting had been judiciously conducted. And as has been seen, the explosive qualities of the mine gas are more marked at the working places furthest romoved from the intake, so that an explosion in a continuously ventilated mine is likely to involve all the workings.

I am inclined to think that some of the advocates of moderately split or unsplit air-currents are influenced too much by the brisk breezes of air which are used in continuous mines. They appear very satisfactory; there is an abundance of air to inhale, but the quality of the ventilation is really the crucial consideration. A baleful wind, full of carbon dioxide, firedamp or nitrous fumes, or deficient in oxygen, is but little preferable to a milder breeze of air fresh from nature's filters outside the mine.

Legislative Action in Regard to Splits

We find that some, or all of these considerations (we may not be able to determine which) have caused the legislators of Pennsylvania to require that not more than 70 men shall work in one current in a bituminous mine. The law of West Virginia puts that number at 60, though these States permit mine inspectors to increase the numbers to 90 and 80 respectively. Utah requires not more than 75 in a split.

When splitting is omitted, doors are frequent and an open door near the intake end of the workings is the equivalent of a stopped fan. The Pennsyl-

vania bituminous-mining law obviously does not favor their use. "No permanent door," says Art. IX, Sec. 1, "shall be erected or allowed to remain in the main entry in any mine, unless its removal shall be deemed impracticable by the inspector." The objection to doors is sixfold; they leak, they cut off the ventilation whenever a trip passes them, they may be left open and cause an explosion, they too often involve expense, and in one case at least a door by ignition has caused a mine fire followed by a disastrous explosion; moreover, in many cases on steep-grades they are a menace to driver and mules and destroy rolling stock.

Arguments against Splitting

Looking at the other side of the question, we have mines with the air split till it travels so slowly it has no vitality. This is to be avoided. Such air cannot sweep firedamp or carbon dioxide. The small amount of air arranged to travel in any split is unequal to the work of diluting the gases and still more unequal to the work of removing them. But it is feasible with good main airways and powerful fans to provide plenty of air because the splitting makes the resistance low, so that plentitude of air is obtained without excessive velocity in the working places. Unfortunately, the average mine is conducted on a slow plan. Too many headings are working at once, and none working at very high pressure, and as regulation is usually unscientific, the slowest working places have air in plenty and the others hardly enough to deflect a light.

The British Colliery Lass

The coal-mining industry in America has not tolerated the employment of women in or about the mines; through legislation, English practice is about to adopt the same principle. A few comments on the subject may interest Coal Age readers.

The British Coal Mines Bill, having passed through the committee stage, will be reported to the "House" for third reading this autumn. A provision has been inserted in the bill to the effect that no girl or woman, other than those employed on or before Jan. 1, 1911, shall be permitted to engage in colliery (pit brow) work at any time. The government does not approve the clause and at the third reading will endeavor to have it expunged.

Some extravagant arguments have been employed, both on behalf of and against the employment of these women, who have been described as the "Junos of the pit brow." It may be said that the work they have to do is neither so bad nor so good as opposing parties have endeavored to prove. There are many sturdy, bright-eyed women among them; but while occupation in the open air may have transformed some of them into living embodiments of the classic Juno, it must be confessed there are others less fortunately circumstanced.

Occasionally cars get off the rails, and to replace them it is necessary for the girls to exert their utmost strength. As this is work to which as a sex they are not accustomed, there is considerable liability to overstrain. Where cars do not have to be handled by the girls, objection to their employment is less pronounced.

Girls' Pay Seldom Exceeds $2.50 per Week

It is important to note that the Miners' Federation of Great Britain has expressed the opinion that the work is not fit for

Type of British Colliery Lass Employed in Lancashire Field

women and girls, but even here there is a suspicion that their earning power regulates the view in some measure, for she is a fortunate pit-brow girl who exceeds $2.50 a week.

Whatever the ultimate decision may be, the deputation sent to the Home Secretary to protest against the new clause has made the worker on the pit brow the "girl of the hour." Everywhere the girl members of the deputation were received with interest and respect, and they were even taken to have tea on the terrace of the House of Commons, being also afforded an opportunity for "doing" the show places of the city of London. Undoubtedly it was the supreme moment in the lives of many of the girls, who will look back with pride and pleasure upon the "picnic," whatever fate may have in store for their occupation.

While they created some stir and sensation in their picturesque clogs and shawls, the lassies, during their visit to London, were admittedly welcomed with some little amusement. There was greater interest in the "Juno of the Pit Brow" than sympathy for the cause she had traveled so far to advocate.

Wigan, England.

Gas and Oil Lines as a Menace in Mining

So far we have no record of gas lines being broken by surface movement consequent on mining accompanied by the contamination of the mine air by the escaping gas. In fact where blowing fans are used the mine pressure is greater than the atmospheric, and there is no tendency for gas to enter the mine unless the pipe is confined by being buried beneath the surface. It is owing to this last condition that the Consolidation Coal Company is arranging for the uncovering of all buried gas lines of small diameter passing over its mines.

The larger pipes are usually left in situ, and a contract entered into with the gas company providing for the sale of sufficient coal to maintain the gas line in place without danger to the miners below. It is said that the gas companies show a keen sense of their obligations to coal companies in this matter, readily permitting the coal company the use of the maps for the purpose of locating all wells and pipe lines and making every provision to protect the mines from damage, though the mining law of West Virginia is deficient in provisions covering this necessary coöperation between mining and gas or oil companies.

When wells are located, the coal company is informed and a location satisfactory to that corporation is chosen. These general statements do not refer to the smaller gas companies. To watch and arrange for the control of these, a man is engaged to keep himself posted as to the erection of new rigs and the building of new lines. The public prints recently gave a somewhat lurid account of the flooding of a mine with oil from a line destroyed by mine workings. Whatever the degree of truth in that sensational story, the facts remain that when the coal bed mined is thick and the breaks consequently large, such floodings or seepages are to be dreaded and their occurrence avoided.

A German method of lessening dust in longwall mining is to force water at high pressure into the face through the drill holes, thus saturating the coal as well as helping to break it down.

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

First Aid Work

SPECIAL CORRESPONDENCE

About the year 1891, Thomas Boundy, living in the anthracite-coal town of Jermyn, Penn., wrote a story entitled "Martin Diamond's Ambition: A Tale of the Mines." The hero of the story was a motherless boy, who, while studying to become a physician, found it necessary to work part of his time in the mines. One day an accident occurred and Martin, through the elementary knowledge gained from his studies, was enabled to be the means of saving two or three lives.

Before the story was printed, the manuscript was submitted to Dr. M. J. Shields, then a practising physician of Jermyn, for corrections and suggestions. Later the story was printed in the *Jermyn Press*, but before its publication Dr. Shields had decided to crystallize the lesson drawn from Thomas Boundy's story, and Jermyn, Penn., became the birthplace of the first-aid association movement in the coalfields of this country. Dr. Shields and Thomas Boundy continued for some years to nurture the "infant plan." In 1900, together, they published a "First Aid Handbook."

The great growth of the movement and the relation of Dr. Shields to its present activities as lieutenant of the U. S. Medical Relief Corps, working directly under Major Lynch, of the American National Red Cross Society, are too well known to require further mention at this time, as the purpose of this article is to deal with the social value of the first-aid movement in mining communities rather than with its history.

A Response to Natural Law

Herbert Spencer said that to understand sociology (the science of society) one should have preparation in the study of biology (the science of life). We know how the various parts of the body coöperate—one part contributing to the needs of another. You stumble and bump your knee, and how quickly the hands respond to the "emergency call" of the knee and rub away the pain! The response of the operators and men in the first-aid movement has been similarly prompt. In the span of a few years, we have seen the appointment of mine inspectors, the starting of the first-aid movement, the provision for scientific mine-rescue work, the opening of mining institutes, State-wide and local, and the creation of the Bureau of Mines, so that today the subject of mine safety is the concern of all the more intelligent men around the mines, the operators, physicians, foremen and other employees. The extent of the change we cannot easily realize without reflection, so steadily and naturally has it taken place.

The Need of First Aid

At a soft-coal mine, a few years ago, a Polish carpenter was repairing a tipple. While fastening a timber he reached out too far, lost his balance and fell to the railroad. Several bones were broken, his head was severely cut and skull fractured. The hospital was 35 miles away and no means of transportation except the local combination train which was not due to leave for a couple of hours.

Many willing hands and sympathetic hearts would gladly have responded to the moans and pleading of the injured man, but not one of his fellow workmen present knew how to give that "First-Aid" that might have meant relief and life to him.

Finally the doctor came, unfortunately a student fresh from a medical college—long on cigarettes and professional bearing, but short on the horse-sense and deep human sympathy that we feel assured mark him in these later years. Well, he gave the fellow a "jab" of morphine, lit a cigarette and told the men to get the "hunky" on the train and he would take him to the hospital.

Think of that ride to the hospital! Thirty-five miles away—changed from one train to another four times—wounds and fractures not dressed! He died in the hospital.

VIEW OF RECENT FIRST-AID MEET, ANTHRACITE COAL COMPANIES, INKERMAN, PENN.

The men composing the first-aid associations and the "squads" in the various communities are of the progressive type. The nature of the work is evidence that these men are inspired by unselfish motives and the constant practising of the principles of the movement increasingly develops the altruistic spirit. This spirit once aroused leads them to take part in the general activities of their home communities. Thus their awakening consciousness finds opportunity to express itself in a way that contributes to the general welfare and progress.

The regular contact the men have with the physicians who instruct them is of more than "technical" value. I recall a pleasant and instructive meeting with an association. The physician in charge led the men in an interesting discussion on anatomy and physiology, then he talked to them on laws of health and sanitation and closed his discussion with a strong appeal to the men on the opportunity to serve their fellow men not only when injured but in the ordinary course of home and community life.

The deep emotion that is aroused in the men by the knowledge that the general public and the chief officers of State and nation are watching and commending the work being done, enlarges their humanity. Then the discipline of the training and the competition in the contests develop that self control which is imperative in the betterment of human society.

The Liquor Problem in Mining Communities

In the first place we state most emphatically that all miners do not drink liquor, and that among the miners we find many of our most sober and industrious citizens. But that there is a serious liquor problem in mining communities and that the problem requires practical consideration is generally conceded by mining men.

A study made recently, with the co-operation of several men prominently identified with coal mining, revealed several interesting facts.

First. A mine superintendent with over 40 years' experience in coal mining and a close observer of the general conditions prevailing in mining communities, says: "I don't know of anything that has caused such blight, shame, sorrow and ruin in the homes of the miners as that resulting from the liquor traffic.

"One of our miners beat his wife without mercy. She was left in a helpless condition and required the services of a physician. In order to discover the facts and endeavor to prevent a recurrence of the beating, I had the man, his wife and the wife of the saloonkeeper brought to the office. I learned that the wife was compelled by her husband to keep whisky in the house all the time and that sometimes he would drink a quart after supper, and if the supply ran out the wife would receive a beating.

"A short time ago a miner's wife came to see me the day after pay day. She asked me to speak to her husband. He had received his pay the day before and had gone to a saloon with it and was still there. She said they had five children and she had no money to buy bread and shoes and no money to pay rent. These are but sample cases. There are hundreds of them." *It is a social problem.*

The Economics of Insobriety

Second. In some instances the normal production of the mine is reduced from 10 per cent. to 15 per cent.

A well known mine manager states that, "Last week we lost fully 15 per cent. of our normal output on account of the liquor consumed at a couple of weddings and christenings."

Fifteen per cent. reduction of the normal output at that mine in one week! *It is an economic problem.*

One coal company official says: "Were it in my power I would destroy the whole liquor traffic. But as that is impossible under present conditions, the only thing left for those of us who interest ourselves in the welfare of the men and the industry is the *regulation* of the traffic, and here you come up against a variety of opinions, all advanced by well meaning people, but many of them impractical."

I recall an instance where a coal company tried to prevent the sale of liquor to the men employed in its mines, and three days after the order went into effect, the men went on strike and refused to work until the beer wagons were again permitted to enter the town. The order was withdrawn! *It is a complex problem.*

The Variant Local Conditions to Be Met

Regarding some of the obstacles to be met in attempting to apply remedial measures, we quote a coal-company official who has given the subject considerable study:

"We have to take account of the present status of the liquor traffic, and work within the limits of the law. The Brooks law, which obtains throughout Pennsylvania, is susceptible of a variety of interpretations. This is due to the large latitude allowed the judges of the different countries. Under such conditions, it will be almost impossible for a plan of regulation to be adopted that will meet the requirements of all the counties. Each county must be treated as a separate entity.

The Question of Regulation

"In the counties where there are mining communities, the question of regulation presents itself in a way entirely different from a mercantile or agricultural community. It has usually been considered more difficult to deal with the mining communities because of the foreign character of so many of the population. My experience and observation lead me to the conclusion that this very fact of the majority of the population being foreign ought to make the governing of the communities easier instead of harder. These foreigners are from countries where the evidences of governmental authority are ever before them, and give them a respect for law such as the native born never have. It is not only respect, but borders on fear. Coming to this country, they not only see others violating the law with impunity, but themselves are taught how they can do likewise.

As an illustration: In many mining villages there are licensed saloons. These are supposed to be under certain restrictions as to when and how much they shall sell to their patrons. But these same patrons, foreigners, know that such restrictions are merely nominal, and that the only real restriction is the will of the saloonkeeper, who is in the business to sell all he can. Then in districts where there are no licensed houses he sees the activity of the liquor agent and of the solicitor for orders from the breweries. These various agents operate supposedly under the rules of the local county courts, as issued by the judge. But that they violate those rules is well known to anybody who takes the trouble to watch their methods. And they instruct their patrons how they may violate the rules of court. The sole purpose is to increase their sales.

"I regard this feature of the business, the activity of the brewery agents, as the most difficult we have to deal with, and the most pernicious. Their methods of soliciting orders and delivering the same to houses of the miners make for an increased consumption and consequent intoxication of the people. The final result is a decreased efficiency, so far as the men are concerned, and in the homes a lowering of the social and moral status."

However, there are men in the coal-mining and other industries that have discovered sane, practical methods for dealing with this social and economic problem of the ages in a way which tends to minimize the evil results of the liquor traffic as it relates to mining operations.

The evils of the liquor problem in mining communities can be minimized! We do not intend, in this series of articles, to discuss present or possible liquor legislation, but to present studies of plans that tend to *minimize* the drink evil.

We will deal with facts rather than theories.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Observance of Danger Signals

Examination for inspectorship of mines, bituminous-coal district of Pennsylvania, May, 1909. (By special request.)

1-A. What precautions would you enforce to avoid the danger in mines to employees going beyond danger signals?

I would arrest and prosecute all those violating the law by passing a danger signal. I would instruct the mine foreman that it is his bounden duty under the law to report to me at once in writing all employees who have passed danger signals. I would point out to him that neglect to make such report is a misdemeanor and that the report must be made whether the foreman has personal or other definite information of the violation. See article 5, section 5.

I would instruct the mine foreman to be careful that he or his assistants or his firebosses instruct all non-English speaking miners as to what a danger signal means, using an interpreter for that purpose. Article 5, section 1.

And as signals may be overlooked or misunderstood, I would require that they be as legally provided, uniform, of approved design and in good condition. Failing this I would require them removed from the mine under article 3, section 3, and good standard signals provided.

But where safety lamps are used, I would advise the management to require the firebosses to give out the lamps to the men working in their respective districts and withhold lamps entirely from those men whose places are unsafe.

1-B. What precautions would you enforce to avoid dangers to employees incident to electrical and other mechanical haulage?

To secure the safety of men not engaged in the operation of cars or motors or other haulage appliances, I would observe carefully whether the old haulways comply with the legal provisions of article 4, section 8.

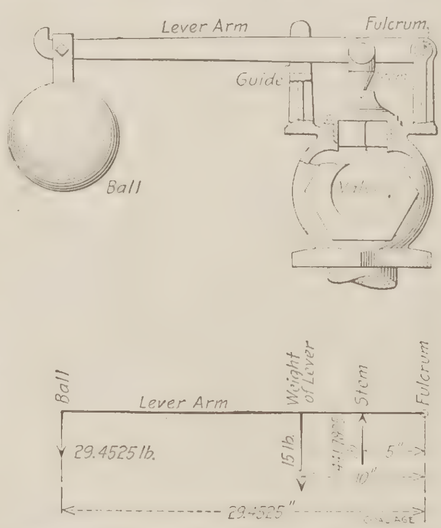
For branch roads, shelter holes must be 30 yd. apart or less and for main roads 15 yd. or less. They must be 2½ ft. deep and 4 ft. wide. Rooms will serve for shelter holes if not further apart and if clear for 3 ft. from the heading rib. I would see that all shelter holes are on one side of the entry, are all whitewashed, level with the haulage road and clear of obstruction.

All entries driven after June 1, 1911, the date of passage of the new Act, should provide a clearance of 2½ ft. continuously on one side of a passing car, unless I believe, as inspector, that the condition of the roof will not permit it.

(The use of electric haulage involves certain wiring and general electric requirements which are very extended and do not properly relate to haulage but to transmission and safety in the presence of gas. These matters will be treated shortly in a comprehensive review on article XI of the new bituminous-mining code of Pennsylvania in a complete and elementary manner.)

Safety Valve Regulation

The distance from the fulcrum of a safety valve to the stem is 5 in., the diameter of the valve seat is 2.5 in., the weight of the lever 15 lb. and the center of gravity 10 in. from the fulcrum. If



FORCES ACTING ON A SAFETY VALVE

the ball weighs 75 lb., how far should it be set from the fulcrum, in order that the valve will blow off at a boiler pressure of 90 lb. per square inch.

The area of the valve seat equals the square of the diameter multiplied by $0.7854 = 2.5 \times 2.5 \times 0.7854 = 4.90875$ square inches.

Such a downward pressure of the lever arm must be provided as will equal 90 lb. for every square inch of valve seat; that is, as there is a valve-seat area of 4.90875 sq.in. there must be a downward pressure of $90 \times 4.90875 = 441.7875$ pounds.

The upper figure shows a typical safety valve with the parts marked thereon, showing plainly its manner of action. Below it is a diagram showing the forces acting on a line, which represents the lever arm. The "moment" of any force, whether that force be a weight or a steam pressure or what not, equals that force multiplied by the distance from the fulcrum. The distance from the fulcrum is what we otherwise term the "leverage." When a body is balanced all these moments sum up to zero, the upward moments balancing the downward. The moment of the stem equals the pressure on the valve, which the stem holds down, multiplied by the distance of the stem from the fulcrum. From what we have deduced that pressure is 441.7875 lb., and from the question the distance is 5 inches.

So the moment $= 441.7875 \times 5 = 2208.9375$ in.-lb. and its direction is upward.

The weight of the lever is 15 lb., as you will see from the question, and the center of gravity of the lever is 10 in. from the fulcrum. The moment of a body is the same as it would be if the weight of it were all concentrated at its center of gravity.

Therefore, the moment of the lever equals $15 \times 10 = 150$ in.-lb. and the direction is downward. We have considered so far an upward movement of 2208.9375 in.-lb. and a downward moment of 150 in.-lb. and the difference between them is $2208.9375 - 150.0000 = 2058.9375$ in.-lb. The moment of the regulating weight or ball is downward and it is the only moment yet to be considered, so it must equal 2058.9375 in.-lb. Its weight is 75 lb. (see question) and so we must multiply 75 by such a number as will make it equal to 2058.9375 or $\frac{2058.9375}{75} = 29.4525$ in. So to provide for the valve to pop off at 90 lb. pressure per square inch, the ball should be moved out till it is 29.4525 in. from the fulcrum.

West Virginia Questions

GLEN JEAN EXAMINATIONS—GENERAL PRELIMINARY QUESTIONS

Ques. E—What are the requirements as to the distribution, measuring and recording of air currents? What must be done when the current is seriously interrupted?

Ans.—Sec. 15 of the mine law says:

"And the mine foreman shall measure the air current *at least* twice a month at the inlet and outlet and at or near the faces of the advanced headings, and shall keep a record of such measurements in a book, having a form prescribed by the chief of the department of mines. An anemometer shall be provided for the purpose by the operator of the mine."

When the current is seriously interrupted, the men must be withdrawn from the mine at once.

Mine Maps Must Be Made

Ques. G—What does the law say in regard to mine maps, (a) with reference to the information to be placed thereon; (b) as to their extension; (c) their accuracy; (d) to whom furnished, and (e) where they must be kept? (f) What penalty is imposed for failure to furnish a lawful map?

Ans.—(a) "The operator or agent of every coal mine shall make or cause to be made an accurate map or plan of such mine, on a scale to be stated thereon, of 100 or 200 ft. to the inch; such map or plan shall show the openings or excavations, the shafts, slopes, entries, airways with darts or arrows showing direction of air currents, headings, rooms, pillars, etc., and such portions of such mine or mines as may have been abandoned, the general inclination of the coal strata and so much of the property lines and the outcrop of the coal seam of the tract of land on which said mine is located, as may be within 1000 ft. of any part of the workings of such mine." (Sec. 5.)

(b) "The operator shall, twice within every 12 months, and not more than 7 months apart, while the mine is in operation, cause such mine to be surveyed and the map thereof extended so as to show accurately the progress of the workings, and property lines and outcrop as above provided; and he shall immediately thereafter notify the inspector of his district, who shall forward to the said operator, or his engineer, the maps held by such inspector to be extended as above required." (Sec. 5.)

(c) "If at any time the chief of the department of mines has reasons to believe that such map or plan or extension thereof furnished in pursuance of the preceding section, be materially incorrect, such as will not serve the purpose for which it was intended, he may have survey and map or plan or the extension thereof made or corrected and the expense of making such survey and map or plan of extension thereof under the direction of said chief of department of mines, shall be paid by the operator, and the same may be collected as other debts are recovered by law; and if found correct, the expense thereof to be paid by the State."

(d) They must be furnished to the mine inspector. (Sec. 5.)

(e) He must keep them among his records, turning them over to his successor in office. No copying of these maps may be made without permission of the operator or his agent. (Sec. 5.)

(f) There is no penalty attached to the failure to furnish a lawful map. "But if the operator or agent of any coal mine shall neglect or fail to furnish to the mine inspector of his district any copy or map or extension thereof, the mine inspector is authorized to cause a correct survey and map or plan of said coal mine or the extension thereof to be made at the expense of the operator of such mine, the cost of which shall be recoverable from said operator as other debts are recoverable by law."

Law Controlling Air Stoppings and Haulage

Ques. H—What are the law's requirements with reference to (a) doors, (b) overcasts, (c) stoppings, (d) breakthroughs, (e) air splits, (f) refuge holes, (g) slopes, (h) haulways and (i) motor roads used for travel?

Ans.—(a) Sec. 12 of the mine law requires that "doors on main haulways shall be avoided in gaseous mines where practicable, and where used they must be substantially built and hung so as to close automatically."

(b) "Overcasts built of masonry or other incombustible material and of ample strength shall be adopted in all mines generating firedamp."

(c) "All stoppings must be built of suitable material, which shall be approved by the district mine inspector." (Sec. 11 and 12.)

(d) "Breakthroughs for air shall be made not to exceed 80 ft. apart in pillars." (Sec. 11.)

(e) "Not more than 60 persons shall be permitted to work in the same air current; provided, that a larger number, not exceeding 80 persons, may be allowed by the district mine inspector where, in his judgment, it is impracticable to comply with the foregoing requirement." (Sec. 11.)

(*To be continued*)

Maintenance of Pillar Thickness

Ques.—A haulway and an airway run parallel and 60 ft. apart between centers; it is desired that they be turned 45 deg. to the left, yet that they maintain the pillar between them at the original thickness. If the airway lies to the left of the haulway, how much further must the center line of the haulway be driven beyond the center line of the airway before the desired turn is made?

Ans.—In the figure, let *A* be a point on the center line of the airway at the turn in the same. Let *B* be a similar point in the haulway, the location of which is dependent on *A* and is yet to be determined. Drop two perpendicular lines *A C* and *A D* from *A* to cut the center line of the haulway before and after the turn of the heading at *C* and *D*, respectively. It is clear that *C B* is the distance being sought, that is, the length that the center line of the haulway must be extended beyond that of the airway before being turned. *A C*, being the distance between centers, must be 60 ft. long.

A C is at right angles to *C B* and *A D* to *B D*. Now, *C B* and *B D* are inclined to each other at 45 deg. It is easily seen that lines which are at right angles to other lines are inclined to one another at the same angle as are those other lines to each other. Hence *A C* and *A D* are inclined to each other 45 deg., and that is equivalent to the statement that *C A D* is an angle of 45 deg. Since the triangles *A B C* and *A B D* are precisely similar, angles *C A B* and *D A B* are equal. Therefore, *C A B* must be half as large as *C A D*, or must equal 22 deg. 30 min.

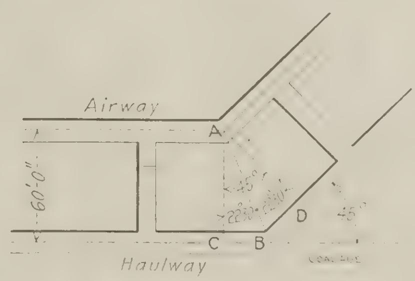
$$\frac{CB}{CA} = tan. CAB = tan. 22\ deg.\ 30\ min.$$

But

$$CA = 60\ ft.$$

$$CB = 60 \times tan.\ 22\ deg.\ 30\ min. = 60 \times 0.4142\ ft. = 24.85\ ft.\ or\ 24\ ft.\ 10\tfrac{1}{4}\ in.$$

Thus the haulway must be driven 24 ft. 10¼ in. at its center line further than the airway at its center line in order that on making the required turn the thickness of the chain pillar may not be changed. It will be seen that, whatever the angle of turn may be, the distance of retarded turning always equals the distance between the lines considered, multiplied by the tangent of half the whole angle turned, and that the longer heading along the lines considered is longer by twice the distance of retarded turning.



Maintaining Pillar Thickness

Example—If angle of turn is 15 deg., retarding of turn is 7.89 ft. If angle of turn is 90 deg., retarding of turn is 60 ft., where the distance between center lines is 60 feet.

If angle of turn is 120 deg., retarding of turn is 86.60 ft. where the distance between center lines is 50 feet.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

The date for opening the controversy involving the West Virginia coal region and the Pittsburg bituminous region as competitors for the Great Lakes coal trade has been set for Oct. 23. Louis D. Brandeis, the Boston lawyer, who has appeared in several important cases before various government bodies, including the advanced-rate case, before the Interstate Commerce Commission, held a conference here on Sept. 28, for the purpose of consulting with witnesses and arranging the order of presentation of argument.

The case in which he will appear is Boileau vs. certain railroads. The complainant is a mining engineer of Pittsburg, who has become interested in the situation, while the roads concerned are those chiefly engaged in moving coal from the bituminous region to the Great Lakes. The point at issue is a request to the Interstate Commerce Commission to reduce the rates on coal for the short haul from the Pittsburg district to lake ports, these rates being now about 88c. a ton, while the rates from the West Virginia district to the Great Lakes region, a haul several times as long, are about the same.

The argument of the complainant in the case is that the West Virginia coal ought to be allowed to go direct to tidewater, while the Pittsburg district coal should find its natural outlet in the Great Lakes region. Propositions have already been made to the shippers who are agitating the question, looking toward an increase of the West Virginia rates, but they have not been content with that solution of the question. They want the rates from the Pittsburg district reduced and they will urge, as in the advanced rate cases, that the coal roads serving the district are making so large an income already as fully to warrant the reduction in rates and yet leave them adequate earnings.

Connellsville Coke Rates

The controversy in regard to the coke rates from the Connellsville district to South Chicago bids fair to rival in severity and importance the issue raised by the West Virginia coal-rate cases. Briefs have just been filed in this controversy on behalf of the Wisconsin Steel Company vs. the Pittsburg & Lake Erie Railway Company in complaints affecting the rates from various points in the Connellsville district to South Chicago, Indiana Harbor, and other consuming ports.

The Coal Roads' Case

The Federal Government has filed in the Supreme Court of the United States at the opening of the October term, its new brief in the so called "coal cases." This is the case of "the United States appellant vs. the Reading company *et al.*," etc. Cross appeals are brought from the United States Circuit Court of the eastern district against the Philadelphia & Reading, the Lehigh Valley, the Central Railroad of New Jersey, and other roads and their affiliated coal companies. The argument of the Government reviews the history of this protracted litigation in the lower courts and then makes an assignment of error.

The principal errors assigned by the Government, stated broadly, are the dismissal of the charges in respect to (1) the general combination, (2) the 65 per cent. contracts, (3) the combination of the Erie railroad and the New York, Susquehanna & Western railroad and their coal companies, (4) the combination of the Philadelphia & Reading railway and the Central Railroad of New Jersey and their companies, (5) the holding by the Erie railroad of the capital stocks of the Pennsylvania Coal Company, the Delaware Valley & Kingston railroad, and the Erie & Wyoming Valley railroad, (6) the holding by the Lehigh Valley railroad of the capital stock of Coxe Brothers & Co., and (7) refusal to dismiss without prejudice what was dismissed.

A lengthy description of the anthracite coal deposits is given and the coal tonage of the various roads is analyzed and described. Argument is presented to show that the interests of the defendant railroads in the shares of coal-owning companies and in anthracite coal lands are in violation of the constitution of Pennsylvania; that the railroads engaged as defendants, in transporting coal of the same kind from a sole and restricted area of production to the principal market, are competitive, although their tracks may not reach the same mines; that all the defendants are engaged in a combination of general scope by which the Reading company and other railroads and their affiliated companies control the anthracite-coal business, and that the 65 per cent. contracts thoroughly discussed in the lower court, whether considered as part of a plan or singly, restrain trade in violation of the Sherman law. Argument is also presented to show that the control through stock ownership by the roads of the various companies mining coal is a combination in restraint of trade.

Pennsylvania

Scranton—One of the oldest and largest breakers in the anthracite region, the Hampton, of the Lackawanna company, is to be demolished within a short time and the coal which was handled there will be sent to the Hyde Park and the Continental collieries, Scranton.

The executive boards of the three districts of the anthracite miners' union have issued a call to all of their constituent locals, announcing that the annual convention will be opened at Pottsville on Monday, Oct. 30. It is at this convention that the demands of the miners, which are to be embodied in the agreement to be submitted to the operators, will be considered and formulated.

Wilkes-Barre—The East Boston breaker of the Payne Coal Company, near here, burned Oct. 3. The loss is placed at $100,000. Smoke filled the passageways of the mine, and at first it was thought that four pumpmen had been suffocated. The men, however, made their way out of the workings by a second opening. Four hundred and thirty men and boys are thrown out of work.

Drifton—Five men were drawn into an air shaft and smothered to death by an inrush of culm at the Drifton colliery of the Lehigh Valley Coal Company on Oct. 4. The men were engaged in tearing down a 40-ft. stack at the top of the air shaft, which was surrounded by a bank of slate and culm. When the stack fell the bank rushed into the opening and carried the men with it.

Ashland—It will not be long before the Humboldt workings of the Lehigh Valley Coal Company, which are awash with water to the top of the slopes as left 15 years ago by Linderman and Skeer when their lease ran out, will be opened for operation. It is planned to work them from the Oneida mines, which are now operated by the Valley company.

Pittsburg—The final transfer of title was made Sept. 30 in the deal by which the H. C. Frick Coke Company, the coke subsidiary of the United States Steel Corporation, purchased the Colonial Coke Company holdings from the Pittsburg Coal Company and the coking-coal holdings of the Monongahela River Consolidated Coal and Coke Company, an interest in

which the Pittsburg Coal Company holds control. The prices are $1450 an acre for about 7000 acres of coking coal controlled by the Colonial Coke Company, this price including nearly 1000 ovens and other improvements, and $850 for about 9000 acres of the Monongahela River company, there being no improvements in connection with the latter acreage, so that the transaction involves about $17,000,000.

West Virginia

The Davis Coal and Coke Company is arranging to open another mine on its property at Dartmoor, which is near Weaver, W. Va. The mine will be located in the Beaver Creek seam district, and will, in all probability, have a maximum capacity of 1000 tons daily.

The United States Coal and Oil Company, which has extensive holdings in Holden, W. Va., has purchased 25,000 acres of undeveloped coal land on Blackberry creek, in the eastern part of Kentucky, and the operations in this section promise to rival in importance those in Logan county. The development of this land will be started at once, it is said.

Illinois

Edwardsville—An attempt to sell the personal property of the De Camp Coal Company was stopped by an injunction. The execution for the sale was issued after 160 miners sued the company for a month's pay. The miners claim wages due to the amount of something like $12,000.

The Peabody Coal Company's mine No. 3, at Marion, the top works and washer of which were destroyed by fire last spring, resumed operations, Oct. 1. The washer has not been rebuilt.

Harrisburg—A recent gas explosion in the Wasson mine, killed one, and severely burned twelve.

Centralia—A fire in the mine of the Junction City Coal Company, the latter part of September, caused a heavy loss.

Marion—The "White Ash" mine of the defunct Standard Collieries Company, at Marion, has been allowed to fill up. The new mining machines, cars, rails, etc., were all left below.

Nokomis—Six miners suffered broken legs and two were probably fatally injured when the cage in the Peabody mine fell 80 ft. on Oct. 6.

Ohio

Columbus—One of the final details in the reorganization of the Columbus and Hocking Coal and Iron Company as the Hocking Valley Products Company was the filing of a mortgage given by the latter company on all its coal, oil, mineral and timber lands and other property in Ohio to the Bankers' Trust Company, of New York City, as trustee to secure an issue of $2,000,000 of bonds.

Considerable interest has been aroused in Ohio and adjoining coal States over litigation challenging the rates of coal shipments from the fields to the consumer or to lake ports.

In the case of the New York Coal Company, of Columbus, against the Hocking Valley Railway Company, in which the Ohio Public Service Commission ordered a sweeping reduction in rates from the Hocking valley almost to Toledo, the application of the complainant to have the matter reopened was argued Oct. 6. The complainant avers that the reductions made were not all that was warranted by the evidence adduced and seeks to have still more radical reductions ordered. The Franklin County court has granted a temporary injunction restraining the shippers from putting into effect the reduction in rates, but the railroad company was compelled to give a heavy bond to cover shipments made in the meantime.

Indiana

Clay Mining—The miners of district No. 8, comprising Clay county, have taken up the matter of preparing a scale for mining clay and shale. Several of the mines have disposed of the clay, which was formerly consigned to the dump, by selling it to factories, and the miners believe that clay will be dug here after the coal industry has ceased. It is therefore deemed necessary that a mining scale should be adopted now to avoid disagreement in the future.

Weekly Pay—The miners are still agitating the matter of a weekly pay in accordance with the law passed by the last legislature, but it is rumored that the subject will be settled for the present by abiding by the request of the operators to continue the semi-monthly plan until the expiration of the contract next April.

The Ehrlich-Pierce Mining Company has incorporated for the purpose of opening and equipping shafts for mining coal and clay. The company's headquarters will be at Turner, Clay county.

The Miami Coal Company, which last year opened a new mine south of Clinton, is opening a second one within a quarter of a mile of the first, and has recently taken on 100 men and plans to add about that many more within the next ten days. Mines in the Clinton district are beginning to be more active, but the activity usual at this time of the year is not yet apparent.

The Wizard Coal Mining Company, of West Terre Haute, has filed articles of incorporation. The initial capital stock is $15,000, and the declared purpose of the company is to carry on the business of mining coal, clay and other minerals.

Kentucky

The Stewart Coal Company, of Ashland, Ky., incorporated under the laws of West Virginia, has changed its name to the Letcher Coal and Coke Company. It has decreased its capitalization from $400,000 to $200,000.

The Consolidation Coal Company is starting to build a model mining town on Wright's Fork of Boone, in Letcher county, similar to the city of Jenkins, now being built on the Elkhorn, in the Elkhorn coalfield. The Nicola Building Company, of Pittsburg, has already received a contract to build 600 miners' houses on Wright's Fork, the work to be started at once.

Texas

Newcastle—Shaft No. 4 of the Belknap Coal Company, of Newcastle, is nearing completion and will soon be in operation. A very substantial tipple has been erected, which is 66 ft. high.

Washington

Vancouver island coal properties, lying between Nanaimo and Ladysmith, embracing 2400 acres and estimated to contain approximately 30,000,000 tons, have just been consolidated into an operating proposition by Andrew Laidlaw, of Spokane, and J. D. Farrell.

Glacier—Development work at the anthracite-coal camps near Glacier will continue throughout the winter.

Alabama

Flat Creek—A coal washer of large capacity is to be erected at Flat Creek by the Pratt Consolidated Coal Company.

Colorado

Delta—A fire in the Summerset mine of the Utah Fuel Company resulted from shot firing, which ignited the timber. Four miners barely reached the bucket in advance of the resultant gas and smoke. The Government rescue car summoned from Trinidad was not needed. The mine was flooded and the fire easily subdued.

California

Amador County—The W. E. Downs coal mine, near Campo, is soon to be opened. A new engine and boiler have arrived on the ground, and it is understood that the shaft will be unwatered immediately and the development work commenced.

Oklahoma

McAlester—A fire destroyed the tipple, the washer, boiler and engine houses and several other buildings about the mine of the Milby & Dow Coal Company at Dow. The loss is estimated at $20,000.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The general tone of the coal market, with a few exceptions, is dull and heavy; however, an optimistic view is taken of the expected winter trade. The protracted summer that prevailed in most sections, particularly in the East, the curtailment policy of a number of the large steam users and the smaller crops in the Northwest, have had a singularly depressing effect on the coal trade generally.

In the Eastern market, prices seem at times about to reach the low point of 1909, and contracts are made to suit the purchaser. The mines of the Pittsburg district are working from 60 to 70 per cent. capacity, which is lower than during the same period of last year. Excess of production is evident throughout the East and prices are only moderately firm.

The anthracite trade is normal, both East and West. The coke trade has suffered as a result of the curtailment in production of pig iron, upon which it is directly dependent.

The Rocky Mountain and Pacific coast trade is in much better condition, being nearly normal. Shipments in from Australia to Pacific-coast points are a number of cargoes behind, and the probability of transportation troubles due to strikes on the Harriman system are making the trade active.

New York

The better grades of steam coal, of which there was an increased tonnage contracted for this year, are now moving on contract in substantial volume. At this season, and until navigation is closed by ice to the shoal-water points, the volume is constantly increasing; the consumers whose only method of transportation will be cut off when the rivers freeze, are stocking up to carry them over the period when navigation is closed.

The arriving and the standing tonnage at the New York piers, while not large, is sufficient to meet the demand, as the mines producing the better grades of steam coals are now working full time, and have had the benefit, for the past two or three weeks, of a satisfactory car supply. There is but little current business going here at the present time and not much is to be expected, when coal is purchased so largely on "year-around" arrangements, until the producers having the regular business, are unable to take care of their customers.

Inferior-grade steam coals do not find a ready market at the present time, as these coals are not purchased so generally on contracts, and have to depend more on the current demand for business. The supply of the better-grade steam coals is equal to the demand, and the inferior coals are always hard to dispose of.

Prices at the New York market for better-grade steam coals while not strong, are being held firm, especially by those shippers who are heavily contracted. For the inferior grades, prices are not so satisfactory.

Pittsburg

Bituminous—This year's coal tonnage is not proving as satisfactory as was expected. Production in the Pittsburg district during the first half of the year fell about 10 per cent. behind production in the first half of last year, but expectations were entertained that the second half of the year would make up the loss. This is not proving to be the case, and the year promises to close with a material loss from last year's tonnage, although still with a fairly good record.

Shipments in the lake trade have been uniformly behind those of last year, the total movement of soft coal from all districts in the lake trade through August being about three-quarters of a million tons below last year's tonnage. September, instead of showing an improvement over September of last year, has shown a slight decrease, and shipments during the balance of the season are likely to be light.

The demand for domestic coal was slow in opening up, but is now of good volume and the movement is practically normal. Demand for coal from manufacturing industries has shown a slight improvement since Sept. 1, as compared with July and August, but is hardly equal to the demand at this time last year. Operations at mines in the Pittsburg district average between 60 and 75 per cent. of full capacity.

Prices are moderately firm and at about the same general level as had obtained through the year. Slack coal has stiffened a trifle, owing to the lake shipping season being nearly over; lake shipments, being of ¾-in. coal, produce an abnormal quantity of slack. While a month or two past, sales were being made freely at 60c. and less, the market is now quoted at 65@70c., with little tonnage moving below 65c. Nut coal is a trifle easier, through heavier production of 1¼-in., and is easily obtained at $1.10. Mine-run continues to be quoted at $1.15, and this price is not generally being shaded, ¾-in. being held at $1.25 and 1¼-in. at $1.35@1.40, a number of producers holding $1.40 as their minimum.

Connellsville Coke—The year thus far has been the poorest the Connellsville coke trade has seen since 1908, particularly as to tonnage. The output this year to date has averaged only a trifle above 300,000 tons weekly from the Connellsville and lower Connellsville field, the poorest average since 1904, with the exception of the year 1908. The outlook is for a production of about 16,000,000 tons.

In this loss of tonnage the Connellsville coke trade has followed the iron industry, which consumes almost its entire output; prospects are that production of pig iron this year will be about 23,750,000 tons, the smallest since 1905 with the exception of 1908. The year's Connellsville coke production, however, shows a somewhat greater loss, as compared with records of a few years ago, than does this year's iron production. In other words, a slightly smaller percentage of the country's total pig-iron production is being made with Connellsville coke than was the case four or five years ago. This change is due partly to the growth in byproduct coke manufacture and partly to increased use of other cokes from this general district.

The economic question of the day is whether the original Connellsville district (including the addition of a decade ago, the lower Connellsville, Masontown or Klondike) will ever adopt the byproduct process. Old-time operators can hardly conceive of such a possibility, while others shrink at the enormous capital investment involved. The United States Steel Corporation, by far the largest interest, is so positioned as to use Connellsville coal in byproduct ovens, if at all, by shipping the coal to the byproduct plants located at the blast furnaces. Every steel interest which considers the adoption of byproduct coking, pays great attention to the question whether an easy offset to a considerable part of the capital investment in byproduct ovens may not be found by using coal from another district, in which an acreage sufficient for a half century's supply may perhaps be purchasable at much less than a Connellsville acreage sufficient for a couple of decades.

The Connellsville coke market has been extremely quiet in the past fortnight. Nearly all furnaces now operating have contracts covering either the balance of this year or a longer period. A very few are uncovered, but a month ago concluded it would be cheaper to buy coke from month to month for the rest of the year than to pay the considerably higher price demanded on three- or four-month contracts. The prompt market is firm at \$1.50@1.55, contracts over balance of year being nominally \$1.70@1.75.

Foundry coke is quiet, consumers being covered by contracts. Odd lots of prompt 72-hour coke of standard grade can be picked up at \$1.80@1.90, cokes selling at less than \$1.80 being generally inferior. Contract coke of standard grade is quoted at \$2@2.25, the favorite contract price being \$2.10.

St. Louis, Mo.

The condition of the coal market in St. Louis has been unsatisfactory from an operator's standpoint, and while coal has been going at a reasonable figure (as far the retailer is concerned), the domestic trade has not been as good as usual at this period of the year. There are some good reasons for this falling off in trade, the principal one of which is the crusade against the smoke nuisance.

The shipping interest are making less money now on their coal than they were last June, for a fall business was anticipated at that time, and on the strength of this expectation, prices kept up. At the present moment, with everything to indicate an overproduction, there is not much to be hoped for in the way of any immediate advance in prices.

Standard coal from the territory adjacent to East St. Louis, and coming in on the 52c. freight rate, is selling as follows per ton f.o.b. the mines:

2-in. lump	\$0.90 to \$0.95
3-in. lump	0.95 to 1.00
6-in. lump	1.05 to 1.10
Mine-run	0.75
Screenings	0.25 to 0.30

The higher-grade coals from the Standard field are bringing anywhere from \$1.75 to \$2.25, at the mines, but the supply of this coal has exceeded the demand for several weeks.

The middle-grade coals from the Standard field, such as Mt. Olive, etc., are bringing anywhere from \$1.15 to \$1.25 at the mines for domestic lump, and various prices on other sizes.

There is practically no Springfield coal coming in, and very little from any other field, with the exception of Williamson and Franklin counties. Some tonnage from Murphysboro Big Muddy is moving in at from \$2 to \$2.25 at the mines for domestic sizes. In the northwestern market, this coal is known as New Kentucky, and is without question the best coal produced in the State, in any great tonnage.

Franklin and Williamson county prices per ton are as follows, f.o.b. the mines, taking a 67c. freight rate to St. Louis:

WILLIAMSON	
6-in. lump	\$1.40 to \$1.50
3x6 egg	1.40 to 1.50
No. 1 nut	1.05 to 1.15
No. 2 nut	0.90 to 1.00
Screenings	0.35 to 0.40
Mine-run	0.90 to 1.00

FRANKLIN	
6-in. lump	\$1.60
3x6 egg	1.50
No. 1 nut	1.40
No. 2 nut	1.15
No. 3 nut	0.85

There is some coal moving in from the Du Quoin field at various prices, taking a 57c. freight rate. There is also some little coal moving in from Montgomery county, but not in any great tonnage. There has been a fair movement of anthracite in all sizes, but not as great as might be expected, and chestnut is somewhat hard to get for this market. During the past month more than 100 cars of West Virginia smokeless has come in, and there is still a fair tonnage moving. Anthracite and smokeless f.o.b. St. Louis are quoted as follows per ton:

Chestnut	\$7.20
Egg and stove	6.95
Stove	6.70
Smokeless lump and egg	\$4.75 to \$5.00
Smokeless mine-run	3.75

The tonnage of gas-house and byproduct coke has exceeded this year the tonnage of any previous year, and is still moving in good volume. Gas house is worth from \$4.65 to \$4.75, and byproduct is going at about \$5.

Indications are that there will be a rise in the domestic market on all the bituminous coals in the course of the next 10 days, as the domestic supply has not been laid in, and with the first touch of cold weather, the demand will tax the capacity of delivering companies.

Chicago

Officials of the Illinois Central deny that there has been any serious interruption to the movement of coal on that line as a result of the pending strike of shop workers.

J. K. Dering and C. M. Moderwell have been elected directors of the Chicago Coal Dealers' Association.

Prices in net tons to retail dealers and steam users are quoted as follows:

	F.o.b. Chicago	At mine
Steam lump	\$2.07	\$1.25
Mine-run	\$1.82 to 1.87	\$1.00 to 1.05
Screenings	1.02 to 1.12	0.20 to 0.30
FRANKLIN COUNTY		
Lump, egg and nut	\$2.70 to \$2.80	\$1.65 to \$1.75
Screenings	1.45 to 1.55	0.40 to 0.50
CLINTON		
Domestic lump	\$2.17 to \$2.27	\$1.40 to \$1.50
Steam lump	2.00 to 2.10	1.25 to 1.35
Mine-run	1.77 to 1.82	1.00 to 1.05
Screenings	1.12 to 1.22	0.35 to 0.45
COKE		
Connellsville	\$4.50 to \$4.65	
Wise county	4.50 to 4.65	
Byproduct, egg and stove	4.75 to 4.90	
Byproduct, nut	4.55 to 4.65	
Gas house	4.75 to 4.90	
CARTERVILLE		
Lump	\$2.65	\$1.60
Egg	2.65	1.60
No. 1 washed	2.70	1.65
No. 2 washed	\$2.15 to 2.30	\$1.10 to 1.25
HARRISBURG		
Domestic lump and egg	\$2.60	\$1.60
Mine-run	2.15	1.15
Screenings	\$1.40 to 1.50	\$0.40 to 0.50
Springfield Domestic lump	2.07	1.25

Boston

Bituminous all-rail has been generally slow. The low prices at tide cut away a considerable tonnage that would normally be railed from Pennsylvania, and all the shippers have suffered on that account. The mines with better established selling connections are now getting fair business, but the operators have been obliged to make as low figures as have obtained within recent years. Prices have ranged from 85c. on coals higher in volatile to \$1.30 and \$1.35 for fancy brands from the more favorably known districts. On the whole, soft coal (all-rail) has been sluggish and dull in tone.

Anthracite, both at tide and all-rail, has been about normal; that is, with no very marked change from other and recent years. The usual April and May demand at tide lasted into June on certain sizes, such as free stove and hard egg. The Kennebec and Penobscot rivers opened much later than in 1910, and the long severe winter left many of the dealers bare of coal. Early in September a cool wave turned consumers toward the dealers with considerable urgency and it was not long before the anthracite shippers had request for prompt shipments on all sizes. A feature of anthracite this season is the still constantly increasing demand for chestnut size, notwithstanding the 25c. advance over stove last spring. This seems the rule with every dealer and one ceases to be surprised that broken and egg are so seldom included in cargo schedules. Pea and the steam sizes have lately shared the generally active market. The year is certain to be favorable for anthracite.

Water freights from Hampton Roads have been about 60c. all season on large tonnage, 3000 tons and upward, with the usual differentials for ports south and east of Boston. The supply of bottoms has been ample, and the rate named is as low as sail tonnage can be run.

Buffalo, N. Y.

The prices of bituminous range from \$2.50 for Pennsylvania three-quarter to \$2.40 for mine-run and \$2 for slack, with some mines selling slack considerably lower than this. Allegheny valley grades sell at about 20c. lower. Coke has been practically lifeless since the iron market became so slack, the price being \$4.25 for best Connellsville down to \$3.50 for stock coke.

Since the freshets that created so much disaster at Austin, Penn., there has been much trouble in the Allegheny valley mines, some of them being completely flooded for a number of days.

The fall trade in bituminous is not

enough yet to stiffen prices, though they must improve as soon as consumers begin to stock up against possible stoppages of production next spring.

Philadelphia

A canvass of the various dealers reveals the fact that orders are coming in more plentifully every day, and in some cases they have run out of certain sizes of coal; their requisitions on the wholesalers are marked rush. October is a good selling month, and the present one gives no indication of going back on the tradition.

Most of the companies are working full time, and it is understood that the demand, except in one or two sizes, covers everything from "broken" to "barley." As a matter of fact, it looks as though there would be a limited supply of the small sizes before the winter is over. The almost infallible index of a stronger market lies in the fact that most all of the individual operators are now holding to circular prices, except in some cases where an inferior grade of coal is offered, and the shading of prices with these concerns is a necessity. Generally, it looks as though the anthracite trade was on the threshold of a prosperous season.

The bituminous trade is still dull. Improvement is noticed in some grades of coal, but, as a rule, the market has a tendency to stand still, rather than progress.

Cleveland, Ohio

About the only improvement in the coal trade has been in the demand for domestic business, which is a natural coincidence at this season of the year.

Prices for middle district and No. 8 coal are: $1.05 for mine-run; $1.15 for ¾-in.; $1.40 for 1¼-in.; slack, 45@50c.; No. 8 mine-run, 90@95c.; ¾-in., $1@1.05; 1¼-in., $1.10@1.15; slack, 35@40c.

Slack seems to be somewhat of a drug on the market; other conditions in the general trade are depressed, and the usual amount of fine coal is not being consumed.

The lake trade continues spasmodic, a great deal of coal still remaining on cars at Cleveland and other Lake Erie ports, waiting for boats to take the tonnage to the upper lakes. The congested condition of coal at the head of the lakes due to delays in removing it at the upper docks, and the fact that large tonnage boats will not handle coal to the head of the lakes and return light, is the primary cause of there being so much fuel still remaining on the Lake Erie ports.

The ore coming down from the upper lakes, has fallen off materially this year on account of the surplus ore being on hand from last season's shipments. The only way the coal at the Lake Erie ports can be handled this year, is to load the tonnage between now and the close of navigation and take the coal to the head of the lakes and hold it there in storage during the winter months for early shipments in the spring. This will insure an adequate supply for the Northwest during the long winter months.

Cincinnati, Ohio

Of the domestic-coal market in general it may be said that it was better a few weeks ago than it is at present. The volume of sales is greater now than then, but not as much so as the season should warrant. It was thought that the domestic demand had made an unusually early start and preparations were made by wholesalers to meet a continuing and growing market; however, for some reason, there has been a lull, and the sales seem to be only about what are forced by the condition of the weather. Reports from the northern part of the State are to the effect that the demand is good, but the weather there is much colder than here.

Local operators and wholesalers have finished a good lake season and, so far as learned, all have been able to complete their contracts. River coal men are coming into their own again here, due to favorable stages of the Ohio river above and the completion of a government dam just below the city, giving them a good local harbor.

Milwaukee, Wis.

Prices on all kinds of coal have been fairly well maintained, and as the time for actual consumption is drawing near, the increased demand will doubtless eliminate any weakness which may have been apparent in the dull season.

Altogether the outlook is decidedly more promising, and the trade in general is bound to show a decided improvement from now on.

Columbus, Ohio

Prices have been well maintained during the past month even under the slow buying of September. The circular issued by Ohio operators, Sept. 1, has been generally adhered to.

Prices which now prevail in Ohio districts are as follows: Domestic lump, $1.50, f.o.b. mines; ¾-in., $1.35; nut, $1.15; mine-run in the Hocking valley, $1.05@1.15; mine-run in eastern Ohio districts, 95c.@$1.05; nut, pea and slack, 50@60c., and coarse slack, 45@55c. There is a good demand for the fancy grades of domestic coal which sell from $1.50 as high as $2 per ton. These grades include rescreened, hand-picked and other specially prepared coals.

Nashville, Tenn.

About 90 per cent. of the coal used in this market is from the western Kentucky fields, and the remainder from the Jellico and Virginia fields. The prevailing prices on west Kentucky coal range about as follows per ton:

Standard lump coal	$1.15 to $1.25
Standard nut	0.95 to 1.00
Mine run	0.80 to 0.90
1⅛-in. screenings	0.25 to 0.30

All country trade has been fairly well supplied with their coal for the winter.

Indianapolis

The retailers and wholesalers say that conditions are not far from normal, considering the fact that warm weather continues. While the mines are working on short time, domestic coal has moved well and steadily, during the past three months, and the supplies equal those of former years at this date.

Salt Lake City, Utah

Prices on our market are firmly held and are $2.25 for lump, $2.15 for nut and $1.25 for slack, f.o.b. cars at mine.

Retail conditions in Salt Lake are both good and bad. Good, in that trade is brisk, having been stimulated by two weeks of cool weather, and by "strike talk"; as a consequence, September business was ahead of the same month in 1910. The bad side results from the fact that the producers have been entirely unable to fill dealers' orders, and the storage or reserve stocks have been drawn upon heavily. These stocks should remain in reserve until Dec. 1, to 15, at least.

Portland, Ore.

Following are the prices asked here, per ton, including cost of delivery to points within the city proper:

Japanese	$7.50	
Washington lignite	$7.00@ 7.50	
Australian	10.00@10.50	
Rock Springs, Wyo.	10.00@10.50	nut $9.50
Diamond, Wyo.	10.00	
Carbon Hill, Wash., lump	10.50	
Carbon Hill, steam	7.50	
Newcastle, Wash	7.00	
Beaver Hil, Ore	9.00@ 9.25	
Blacksmith coal	17.00	
Pennsylvania anthracite	18.00	

The Beaver Hill coal is brought here by steamer from Coos Bay and sells for $8 on the dock.

San Francisco

Stocks of coal are below normal and dealers anticipate an active fall and winter trade. The following are the prevailing wholesale prices per ton at San Francisco:

Wellington, from B. C., clean	$8.00
Wellington, from B. C., average	7.50
Australian, from B. C., clean	8.00
Australian, from B. C., average	7.50
Washington.from B. C., clean	6.50
Washington.from B. C., steam	5.00
Utah, Wyoming, Colorado and New Mexico, for domestic use only clean	8.15

To these prices the retail dealer adds from $2 to $3 per ton, accordingly as delivered direct from cars or from storage.

The Ouptut Of The Mine

> *The Boiler Plant is the Heart of the Coal Mine. Any curtailment of the necessary power means a corresponding reduction in output with increased cost of production.*

When a man's heart is strong, pumping the red blood to every part of his body, he is pretty sure to be in a position to give the best that's in him.

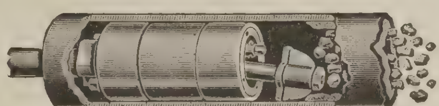
When the boilers in the power plant of the mine are at highest point of steaming efficiency and the power is being transmitted to every part of the mine for the hundred and one different operations, the mine is pretty sure to be delivering its maximum output.

That's why we say the Boiler Plant is the Heart of the Mine. And why the boilers should always be kept at highest point of steaming efficiency. The boilers are not at the highest point of efficiency as long as there is any scale on the tubes, forming a non-conductor for the heat.

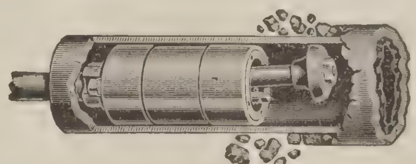
Scale *will* form and especially in coal mine plants where feed water must be taken from the most convenient supply, which nearly always contains not only the ordinary impurities, but also those introduced by contamination with mine water.

There is only one sure way of removing *all* the scale and of *knowing* that all scale has been removed. That is by means of

The Dean Boiler Tube Cleaner



The Dean removing scale from the tube of a water tube boiler.



The Dean removing scale from the tube of a return tubular boiler.

The cleaner that operates on the principle of "*broken-up vibration*," caused by the striking of 3000 to 6500 light blows a minute.

It goes where no inspector can. It cleans 10 to 30 tubes an hour, leaves every tube through which it travels as clean as a gun barrel.

It is the easiest, quickest, most economical way of removing scale, and what is more important, the user *knows positively* that his boiler is free from all scale. Let us tell you why.

Trial Offer And Guarantee

We sell the Dean Boiler Tube Cleaner entirely upon its merits.

We send it for trial on one boiler to let the purchaser see how it operates and prove to his own satisfaction that it does remove all the scale.

We sell it under a guarantee that i will pay for itself within six months or we will refund money.

The Mine Operator, Superintendent, or Manager who realizes the benefit of high efficiency in the plant of the coal mine will send for a Dean on trial.

The Wm. B. Pierce Company

335 Washington St., Buffalo, N. Y.

Form The Habit Of Reading Each Week This Buyers' Finding List

Start now, with this first issue.
The above index is an accurate guide which will lead you every week through the Selling Section of COAL AGE. It furnishes complete information regarding every concern whose advertisement appears in this paper. It tells you "who's who and who makes what."

To be here is a badge of responsibility
To buy from here is a guarantee of satisfaction

Coal Age Is YOUR Paper

LET this one idea sink firmly into your mind—COAL AGE is *your* paper. ¶ It has but a single purpose—to serve the common interests of the men engaged in the Coal Industry.

¶ It is going to advocate—first, last and all the time—reforms and methods that mean *safer* Coal Mining, to hunt out and describe ways and means for *more profitable* Coal Mining.

¶ Your battles are its battles; your problems, its problems.

¶ Look through this issue and you will appreciate the force of this statement. And remember that this first issue is but the beginning, that every week *your* paper is going to grow better—become stronger and more helpful.

¶ You *need* COAL AGE and COAL AGE needs *you*.

Don't miss a single issue of Coal Age—subscribe NOW. Send in your $3—the yearly subscription price for the full 52 issues in the U. S. and Mexico—$4 in Canada, $5 in any other foreign country—TODAY so that you will receive the second issue just as soon as it is out.

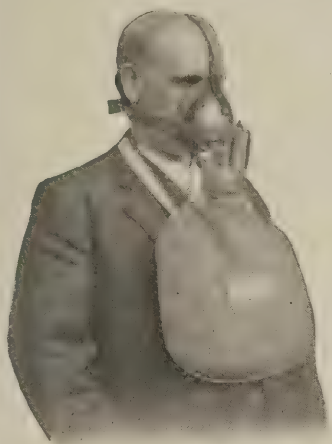
Invaluable In Rescue Work

The Servus Emergency Mine Rescue Apparatus



As an adjunct in Mine Rescue and recovery work, this apparatus is invaluable, weighs but four pounds, supplies the wearer with ample pure fresh air, rich in oxygen, for over one-half hour and it's thoroughly practical for any service. Write for circulars.

Servus Rescue Equipment Co.

10 Johnson Street Newark, N. J.

Why Waste Air?

Why waste air by using cheap Brattice Cloth?

You are obtaining air by mechanical energy that costs you money to generate.

And when that air seeps through a cheap Brattice cloth it is a loss.

So why be penny wise and dollar foolish, by saving money on cheap Brattice cloth and wasting it many times over in wasted air?

Kern's Non-Inflammable Brattice Cloths are made of hard yarn, closely woven.

They are a big economy not only because of the air they save but also because they wear much longer, resist moisture better, and hold better to the nails than the cheap, loosely woven article.

They keep good air on the side where it is needed and enable you to get a larger percentage of air to the working faces.

Why not make a trial?
Write today for Samples.

$55 a Month to $3,000 a Year

Through I. C. S. Training

Mr. Isaac G. Roby, Uniontown, Pa., who is now Inspector, Fifth Bituminous Inspection District, writes us under date of October 10, 1910, as follows:

When I enrolled for the Mining Course with the International Correspondence Schools, of Scranton, Pa., I had had only 20 months of schooling all told. I was employed at the time as assistant foreman, and was getting $55 a month. After enrolling with the Schools, I was soon advanced to the position of mine foreman at $75 a month, which was voluntarily increased to $90 a month. I am now Mine Inspector of the Fifth Bituminous District, at a salary of $3,000 a year.

Correspondence instruction as conducted by the I. C. S. is the finest and most complete in the world today; every young man that desires to advance or better his condition should enroll at once. No one can enroll with the I. C. S. and apply himself to his work without being greatly benefited.

The success of such student should be an inspiration to *you*.

Would you be willing to make a small investment that would increase your salary 100, 200, or 300 per cent.?

To learn how the I. C. S. can help *you* to secure increased earnings, promotion and a happy, successful life, mark and mail the attached coupon. Doing so will cost you only postage and will place you under absolutely no obligation.

SEND THE COUPON NOW

International Correspondence Schools
Box 1104, Scranton, Pa.

Please explain, without further obligation on my part, how I can qualify for a larger salary and advancement to the position, trade, or profession before which I have marked X.

Moments with the Advertising Editor

A Department for Subscribers Conducted by the Service Department of Coal Age

Between you, the reader of COAL AGE, and you, the advertiser in COAL AGE, this department is to be the alternating current of stimulus and information.

Many of the things that will be told here the COAL AGE advertiser knows; and thus far this page will be You, the advertiser, talking through us to You, the reader. Sometimes the reader, the buyer himself, will have space to give his testimony to the advertiser as to what advertising means or should mean to him. The life of the page will flow back and forth, between You—and You.

You, the reader of COAL AGE, invested in the paper to obtain certain values in the editorial columns which we engaged to give, and now you find, when you open the first number, before and after that editorial section, the pages of a Selling Section—commercial ventures of people trying to induce you to buy or investigate things in the Coal Mining field that they have to sell. Was this Selling Section part of the bargain? Let us defer that question a moment, and get at this thing from another angle.

To put it without furbelows, the reason for existence of every honest, alive, coal man is *to get coal out* with the utmost degree of safety, more rapidly, more cheaply (in energy or dollars) than the next man—if he can.

To accomplish this he knows that communion with every other coal man who has ever said anything or done anything out of the rut of the day-by-day, here or beyond the Atlantic, is vital and indispensable. That is why COAL AGE was started.

But he also knows that the "how," the "why," the "where," by which he is to exceed what he has heretofore done, or what the other man is doing, must be yoked with the "what to do it with."

Demand makes supply, and you, that coal man, become aware through hearsay, from a traveling salesman, or through reading advertisements, of machinery, appliances, etc., that square or pretend to square with your situation.

Among those three—the firm whose goods get known through hearsay, the nonadvertising firm whose goods are sold by traveling agents, and the firm which advertises—the latter has to begin with a big handicap.

It has to pay an advertising bill *before* it has sold any goods. That advertising bill is no small one, either, in a paper which halts at no money-limit to secure the best, most authoritative contributions to its editorial columns and whose subscription price hardly more than meets the bill for the white paper.

But the *buyer* of advertised goods has one four-square advantage from the first moment, and when the momentum of sales has begun, to the seller comes an advantage which wipes that first handicap completely out. This is why—

Advertised goods have to be precisely what they are represented to be or the advertising is a self-annihilating boomerang both to the advertiser and the paper carrying the copy. Advertising in a paper which does not give away its advertising pages can pay the man who buys the space only when it brings continued buying, which is impossible unless the goods are what they are represented to be. Thus advertising cuts a gulf between the kinds of goods that can be sold by a fakir who skips on, never to be heard of again, and the kind of goods which have to prove right because the life of the salesman depends on it.

For the advertiser, advertising begins the process right by getting him, without experimentation, directly to the return-givers, the men in that field who read, who think, and who act on reasonable representations.

And before the process has *gone far* it puts the advertiser tremendously to the good in returns, because the total of sales, each with its closely figured but definite profit-margin, multiplies at higher ratio than the ratio of publicity—streaming out beyond the horizon of the man who holds to the junk-pile idea that advertising is a bunco game.

We of COAL AGE know these things; no one has entered this Selling Section whose product has not "lived up to the ad" in other publications of this company or been investigated.

The advertisers in this Selling Section know it; no one of them would have paid money for space here without the round measure of conviction that COAL AGE is to be read in editorial and advertising pages by men who know what they want and recognize a thing's merits through sincere, straightforward statement of them. The ability of COAL AGE to make good with the advertiser, and with the standard we set up to begin with, depends on that—*action* between reader and advertiser.

Now back to that question—was this Selling Section part of the bargain?

We won't answer it, for before long we wager you, the reader, will answer it yourself with another question, viz:

What sort of a bargain would COAL AGE have been *without* the Selling Section?

Moments with the Advertising Editor

A Department for Subscribers Conducted by the Service Department of Coal Age

Last week we talked about the reliability of advertised products. It was shown that a product given advertising publicity in a reputable paper has to be what it is represented to be both because the good name of the publication depends on it and because only continued selling (that is, *continued advertising*) overcomes that initial advertising outlay.

But what of Price?

When a firm spends $50,000 a year on advertising, are not the consumers of its product, excellent though it may be, paying a good deal more for it than they should pay? And then the price that a firm's advertising outlay justifies it in putting on its goods may be the shield under which the rival nonadvertising firm, with a product not quite so good, runs up its prices almost to the same limit—so that whether you buy advertised goods or not, you have to shoulder that needlessly big advertising burden.

Yes, it is true, advertising *has* a bearing on the price of every product you buy, whether advertised or not. But not exactly in the way indicated.

The cost of any manufactured thing, tooth brush or paint brush, toothpick or miners' pick, has two parts—

1. What it takes to produce it.

2. What it takes to get it to the user.

Sometimes the second is larger than the first, but, larger or not, the distribution bill is as real and necessary an element in the total cost of the product as the manufacturing bill. Manufacturing bill and manufacturing could go to the Limbo of the Forgotten if there were no way to get the manufactured thing to the people who need it or to make those who don't know they need it but really do, see that fact. *You* pay this distribution cost in every product made by machinery or human hands that you buy.

The question is, what method of selling is going to cut that distribution cost the lowest? What about ADVERTISING?

Now it may seem an extravagant statement to make, yet it is true that when a firm advertises $50,000 a year, that outlay may mean a *saving* of $50,000 a year to the consumer instead of a burden of that figure. Because—

The multiplied volume of production that advertising-built demand calls for enables the firm to reduce the manufacturing cost of the individual article so much that its total manufacturing expense is cut $2 every time advertising adds $1. Such a ratio as this isn't likely to exist in the case of such individually costly products as mining machinery, yet it is a real factor in the price there too.

And that nonadvertising firm?

The real fact is that instead of being able to shove its price up under the shelter of its competitor's advertising bill, in order to keep in the running at all it has to adopt selling methods *infinitely more costly than advertising.*

Advertising is simply selling by print, manifolding a convincing salesman's words 1,000 or 10,000 or 1,000,000 times, and when this nonadvertising firm passes the printed salesman up for the man-salesman only, or some other selling way, it not only makes a bigger outlay in money and energy to keep in the race in sales with the advertising firm, but it also misses all that wide *general education* of the people in that field or industry into the particular points of its own product—education that, ramifying out, makes for future sales.

Thus the cost of the nonadvertised article *cannot be less* than that of the advertised article; it is likely to be more. And besides that, the responsible well known paper that dictates the printed salesman's words to you, the Buyer, takes its stand between you and the firm whose name is new to you, introduces you to it, tells you where you can find it at every moment, stands behind its guarantees, saving you the trouble of investigation.

If it were not for mediums such as the Selling Section of Coal Age you could not purchase the products advertised therein at the prices their makers will quote you.

Advertising thus is not only the *shortest* route, but it is the *cheapest* route between YOU, THE COAL MAN, and THE COAL MINING APPLIANCES YOU WANT.

This is the True Story of the relation of Advertising to Price!

COAL AGE

Vol. 1 NEW YORK, OCTOBER 21, 1911 No. 2

The Gad and the Man Who Cut It

A FABLE runs thus: Two Surajahs of Hind were minded to mend the conditions of their people. Now there lay nearby a rich Satrapy of Persia. One Surajah, he of Gwalior, spoke thus: "I will build unto my people a school that they may learn to speak unto these rich barbarians from Persia and that they may barter with them." And so he did and the people waxed fat withal.

The other said, "I will build highways; thus may the traffic be great with these rich strangers, who are come from over the mountains." And so it was.

And while yet the Surajahs were in counsel with skilful engravers of stone, so their deeds might be emblazoned that all might know of them thereafter, a murmuring arose.

Then the Surajah of Gwalior said, "Why murmur ye?" and the people said, "Because we have no roads, therefore our commerce is straightened."

And the other Surajah made like inquiry of his people and they made reply: "Sire, our people are dumb men before the Persians. The scholars of Gwalior speak in the tongue of the stranger and lo! where is now our trade?"

Thus it has been and will ever be till water no longer turns the mills or the sun ripens the rice in the meadow.

———o———

Time was when mining had hazards far greater than today. So to subdue these hazards, the operators met them one by one.

The risks of mining did not appear all at once. But as they appeared, someone checked them. Thus the enlightened operators introduced the safety lamp, then the return airway, the trompe, the furnace, the overcast.

Then they ripped out the furnaces. They put gates on the shafts; installed devices to stop runaways; put firebosses to detect gas; fireproofed the stables; concreted the shafts; built headframes of iron; hooded the machinery; put safety stops on the hoists; dampened the coal dust; built stoppings of stone; analyzed the mine air, and stationed boys to tend trapdoors.

Space will not suffice to tell what was done. Still murmurings arose.

———o———

Some operators did more than others. Some took one course, some another. All did much. But the people still raised a cry, "Why not all this and why not more?"

———o———

The operator sees his duty and acknowledges his social obligation. In most cases his fad is safety and the comfort of his men.

True, he likes dividends which muckrakers, yellow journalists and some legislators refuse.

But he has not been unmindful of his duty and he does not always ask how the law reads.

He takes the unwritten law and devises or adopts new means of safety, enforces new rules, which are often bitterly opposed by his employees and their confederations.

He knows the law is not the guide of the good man, but the curb of the rogue, the clamped bars which restrain the thief; and he reads, marks, learns and digests that he may lead the way to safety, and the law corrals the stragglers.

———o———

The operator cut the gad and to the operator it is applied. And the public grasps the small end and applies the other, for a pleasant thing is the use of the hammer on offenders, providing the other fellow is the offender. And, after all, the gad has its uses. We should find it a slow, slow world were it never applied.

Collieries on the Ellsworth Branch

By R. Dawson Hall

A field of recent development with the most modern equipment. The operators have duly recognized the risk attendant on open lights and discarded them at all shafts. Not less modern than the plants are the new methods being pursued to promote the welfare of the operatives.

The field, of which the outlet is the Ellsworth branch of the Pennsylvania Railroad, is of quite recent development, the line being built to Ellsworth in 1900 and extended to Marianna in 1907. The district contains many features of interest from the large scale in which its development has been conducted. Commencing at Monongahela City, on the left bank of the Monongahela river, it extends along Pigeon creek to its headquarters at Scenery hill and thence to the valley made by the waters of Ten Mile creek. The northeastern half of the field follows the valley of Pigeon creek, of which the three branch valleys are as important geographically as the main. The southwestern half is drained by Daniels and Little Daniels runs, which joining, enter Ten Mile creek a little above Zollarsville.

A winding syncline, known as the Waynesburg, divides the field roughly in two, but throughout its length, in the field under discussion, there is a gradual rise in the measures, the coal being about 350 ft. higher near Monongahela City than at Marianna, which village marks the southwestern end of the field. The Bellevernon anticline to the southeast and the Amity anticline to the northwest, are both about 4½ miles distant from the syncline between them, but the steeper rises are toward the former.

In every part of the field, the Pittsburg, the only producing bed in the district, lies below water level. The Monongahela measures along Pigeon creek and its branches and on Ten Mile creek, do outcrop a little, but for the most part over all the surface lies the Permian or Dunkard group of measures, including the Washington formation and in part the Greene also.

Consequently, the field, lying so far below the water level of the entire surrounding country, is a gaseous one. The Marianna explosion, with its death roll of 154, impressed that fact firmly on all concerned from end to end of this field. To protect the mine against the most remote possibility of fan stoppage, the Pittsburg-Buffalo Coal Company has two fans installed, either of which is sufficient to ventilate the mines, and one of these is connected to two engines, so that if one needs repair, the other can take its place. Of course, in practice, it is customary to use one fan and to drive that fan by one of the two engines provided for that purpose.

As a further result of the explosion, the same coal company has installed pneumatic locomotives, though every preparation had been made to haul coal by electrical power. There is every precaution taken to prevent a repetition of the disastrous occurrence of Nov. 28, 1908, and the use of safety lamps alone and the unannounced inspection of men entering the mine, make conditions at this operation very safe. Only recently, a miner, the sole survivor of the Marianna explosion, was arrested and fined for taking a tobacco pipe down the shaft.

Tipple and Washer, Ellsworth Colliery No. 1, Ellsworth, Penn.

Humidity and Firedamp are Measured Once Each Week

At the Ellsworth collieries, both humidity and methane are regularly measured once a week in each section of the mine. The former generally runs from 90 to 100 per cent. of saturation and the latter, in the returns, under 0.5 per cent.

It appears that the gas is found in live, and not in those pillar workings where the roof is broken. It is found in the latter, of course, after a fan is shut down, but only because diffusion is not complete, so that the gas rises and displaces the air. The gas was found in the sinking of the Ellsworth shaft No. 1, when the sandstone of the roof was penetrated, but not before, so that it must be in the coal proper or in the roof-coal and not in the strata above. In the mines of the Ellsworth Colliery Company, electric motors have been employed for gathering. Most of these had a return-wire attachment, but it is purposed to use a crab motor, so that it will not be necessary for the locomotive to travel to the end of a room. Thus, there will be no need for the motor to approach faces of newly cut coal, which is charged with gas and bleeding it freely.

The section of the coal at Ellsworth colliery is very typical of the field and is given in the inclosed illustration. The coal bed at Marianna runs from 5 ft. 6 in. to 6 ft. 8 in., and usually nearer the larger figure.

An analysis based on eight samples of the whole bed in the Amity quadrangle, as used for shipments, is as follows; the figures following on the right being those for run-of-mine coal at Marianna.

COMPOSITION OF PITTSBURG COAL

Moisture	1.86	0.92
Volatile matter	35.95	36.11
Fixed carbon	56.26	56.19
Ash	5.93	6.78
	100.00	100.00
Sulphur	1.12	0.99

It is a good steam and coking coal. There are ovens at Marianna, Ellsworth, Coalburg and Bentleyville, those at Bentleyville being Mitchell ovens. These are, of course, leveled and drawn by machines. One machine can draw, or rather push, 150 ovens in six hours. At both Marianna and Bentleyville there are a number of ovens connected by conduits with the boilers, and these are fired wholly or partly by the waste heat from the same.

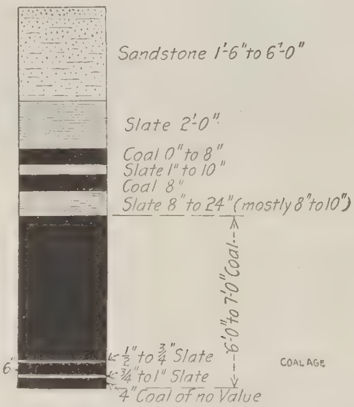
Mining Methods

The system of working at the Ellsworth collieries varies but little from that favored in the Pittsburg district and the

extraction on first mining, contrasts strongly with that of the Connellsville and Georges Creek regions. Instead of a primary extraction of a little over 50 per cent. of the coal, these more easterly districts produce only 13 to 15 per cent. so that nearly all the work is pillar work. The fact that mining machines can only be used in advancing the breasts and in the first cut made thereafter, has something to do with this, but another cause is to avoid the large amount of advance work demanded by more modern methods. In the Ellsworth mines, the width of the pillar is 20 ft. and of the room 22 ft. This is an extraction of about 50 per cent. at first mining. The length of the neck of the room is 21 ft. Rooms including the necks are 250 ft. long. All main entries, which are here driven in the direction of butt entries, are constructed four-fold. The face entries are driven with three openings, while the secondary butt entries have two haulways, one of which is used for a return airway and one for an intake. The chain pillars in the main and face entries are very wisely driven on 40-ft. centers but are protected with equal wisdom by large flanking pillars 100 ft. wide. On the other hand, within regulation distance of the next face heading, rooms are started at the end of the heading and progression in starting and driving rooms and recovering the pillars is from the end of the heading back to the protection pillar of the face heading. The cover runs from 350 to 500 feet.

The Acme mines of the Pittsburg-Westmoreland Coal Company have another



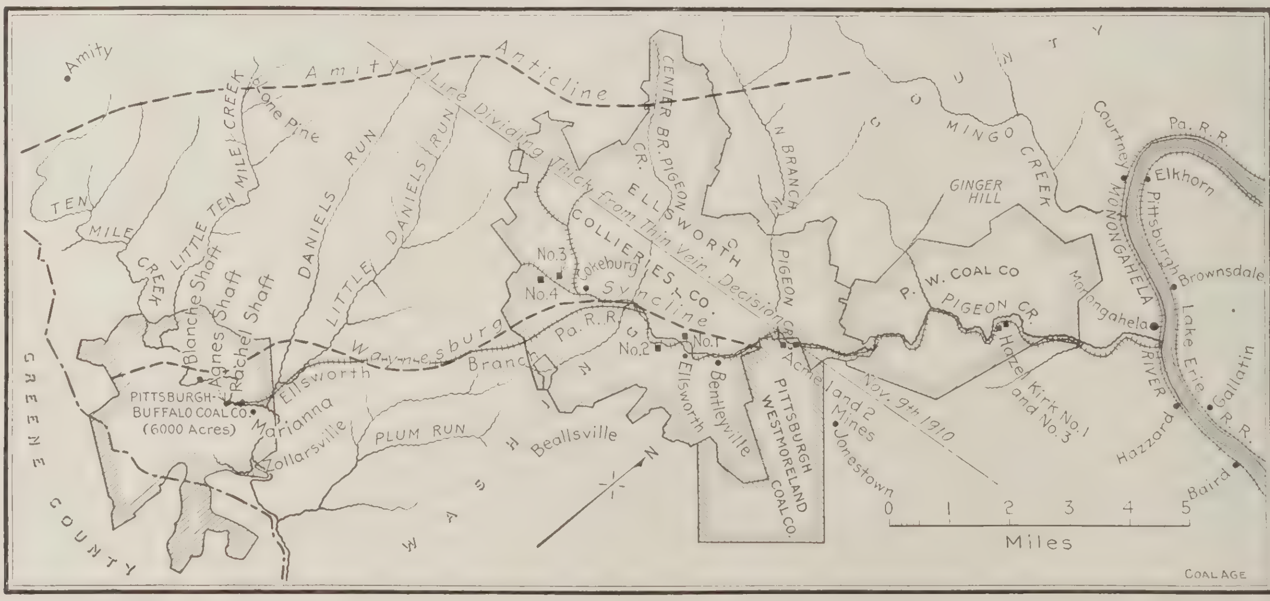
Pittsburg Coal at Ellsworth Collieries

center to center. It is the intention to do retreating work in the future.

The Marianna mining methods are not fully decided on and have hardly passed the experimental stage. The mines have heavier cover than any others, perhaps 650 to 750 ft. is reached in places. But the working is largely under Marianna town and the company hesitates to completely extract all coal from the support of a village on which they have spent so much money for brick houses with modern sanitation, cement walks, etc., and they have decided on a chamber 27 ft. wide and a 6-ft. pillar. They expect that the pillar will crush and one cannot see why a well conceived retreating plan with an attempt to retrieve the last ton of coal would not be preferable.

Sociological Provisions

In an article of this kind there is little place for detailing the new methods of caring for the welfare of the miners outside the mines. The Marianna mines have always been preëminently distinguished for such welfare work. The explosion, and the situation of the town at the end of an unimportant branch line, have made it difficult for such enlightened



The Ellsworth Branch Coalfield, Washington County, Pennsylvania. An Unbroken Body of Pittsburg Coal

the chain pillars in butt entries are 60 ft. through. A fair average of coal extracted is 90 per cent. in room pillars and 75 per cent. only in the chain pillars of the butt entries. The system followed is a peculiar one. One pair of headings is run up with rooms driven right from the right-hand heading and left from the left, the first rooms being started as soon as the 100-ft. flanking face pillar is provided for. The rooms are drawn in regular order as they have been driven up. The next pair of headings is in skeleton, mere headings without rooms with a 250-ft pillar flanking them. When they come system. The main butts are six-fold. The face headings three-fold, and the secondary butts are double. The rooms are only driven from the haulways. They are set with 35-ft. centers and are 20 to 21 ft. wide, leaving a pillar from 14 to 15 ft. wide, the extraction on first mining being 60 per cent. There is a little less overburden to support at Acme, but in places the coal is at least 400 ft. deep. The necks are 21 ft. long and the rooms including necks 250 to 260 ft. in length. The headings of the main butts are centered 60 ft. apart, but the face headings and secondary butts are 50 ft., from

purposes to blossom into full-blown success, though eventually the well-built houses and universally established sanitary sewerage, the amusement hall, wash houses and other comforts will bring the best kind of miners. At present the improvements must appear uncomfortable and undesirable to many of them, largely Pan-Slavs, who have been used to snug quarters in a dirty hut covered by a thatched roof and who measure against the stately discomforts of a good house and a bathroom, the one clean pleasure he can understand, at the end of every two weeks, a fat roll of bills. The Ells-

worth colliery has houses, offices and stores of marked English type and will certainly appeal to the artistic sense, though possibly the houses are not as well lighted as if they had been constructed according to American plans. They are, as at Marianna, all the property of the company. The Ellsworth firm has a dairy farm where milk is sterilized for sale to the miners and is endeavoring by the use of garbage boxes placed along the sides of the road, and emptied every week, to induce the foreign-born families to live more cleanly lives, and very neat is the village, alike where the Americans and Europeans live, but the Italian cannot be induced to relinquish his jackdaw habit of gathering every cast-off box and slat to litter up his yard. To prevent the disposition to drive across the unfenced lots, so marked in mining villages, resulting in mere house sites and roads with an unsystematic appearance, cinder walks, held in place by heavy 12-in. planks staked firmly in position, are being laid. The plank is high enough to keep vehicles in the road. To beautify the town, the coöperation of the school teachers was secured and after the children had been well indoctrinated into the methods of planting, 300 catalpa trees from the company's own grove were distributed free throughout the village, the people of all nationalities taking pride in planting and caring for them. As a result, they look very thrifty and relieve the dull bareness of the house lines. One marvels at the stupidity which makes some operators order a small copse completely cleared for houses, robbing the village to be constructed of the one beauty all people, from east or from west, equally understand—the beauty of foliage. And to protect the trees, the help of the schools should not be disregarded for it is rarely adults who mutilate shade trees.

A String of Coke Ovens at Ellsworth with Boiler Plant Utilizing Their Waste Heat

Standing of the Nations

It is more than a coincidence that the standing of the leading nations parallels their product of the prime mover of civilization—coal. Taking the figures of the report of 1909, the most recent available, we have:

United States, 460,803,416 short tons, Great Britain, 295,427,229; Germany, 239,676,934; Austria Hungary, 53,136,000; France, 41,856,269.

Alone of all the five countries mentioned, Austria-Hungary appears above the order which it deserves as a world power.

Colliery Dwelling Construction

By A. T. Shurick

This is the first of a series of articles which will take up in detail the construction of miners' houses. References on this subject are unusually meager and the methods here described are selected as typical examples of those employed by some of the larger companies and may be taken as the standards for this class of work.

To obtain the maximum economy of operation in the modern coal mine of today, a certain amount of high-grade help is essential, to procure and retain which, comfortable quarters must be provided. This applies not only to the official force, but also to the rank and file, for it is generally conceded that the permanent man has a higher efficiency, and men of this class are often attracted and held by adequate and agreeable living conditions even at times with lower wages.

The selection of a house suitable for the office men and mine officials is not usually a difficult problem. They appreciate and care for any of the small luxuries which a company may feel inclined to install, and are ready to pay the additional rent necessary to make such installations a profitable investment. On the other hand, the selection of a proper house or houses to meet the requirements of the cosmopolitan population which forms the bulk in the average coal camp, is often a difficult problem.

Some companies with a view to bettering the condition of their miners include cellars or bath tubs in designing the houses, which often results in their later having the chagrin of seeing these turned into a stable and coal box, respectively. It seldom happens that a class of miners as a whole will be obtained who appreciate expenditures of this character, although there is nearly always a certain percentage who will, and a few houses of this kind will seldom lack the necessary tenants.

The term "coal camp" usually conveys to the layman an impression synonymous to that of New York's famous Ghetto, or the picture of a straggling road lined with dilapidated "shacks" inhabited by a gun-fighting population of rough-necks. While such conditions may have prevailed in the early history of the industry and still be in effect in some isolated instances, the advent of large capital in recent years has brought with it far-sighted men who appreciate the fact that permanent organization and legitimate business cannot exist under such conditions. For this reason the day of the shack camp, except for temporary construction purposes, is past.

For the average miner's house the question then resolves itself into something between the shack and the "cellar-bathtub-house." While this appreciably limits the range for selection, a surprisingly large number of different designs and grades of construction occur within these limits. I remember one camp having for its subdivisions Papercollar Row, Sandal-Foot Row, Darkest Africa, Japan and Chinatown, each division having a standard design of its own and some several different designs.

This article will take up in detail what is believed to be a house of average design for this purpose. The construction of houses of this character is often undertaken without special plans, specifications, etc., because of their low first cost. Where 40 three- to five-room houses are being erected, the first cost will run about $30,000 or $35,000, when good permanent construction is used and no frills. Unless careful designs have been drawn up it usually develops when the houses go into use that the rafters on a lean-to having a light pitch are too small to carry the snow-load or the floor joists over a particularly long span are too weak. Since the total investment exceeds the amount of a single large house for which detail plans and specifications would naturally be drawn up, this cannot be considered good practice.

Types of Houses

While in some instances the two-story house in used in large camps and where land values are an important item, these conditions do not often prevail and houses of this class are rather the exception than the rule. The house most commonly met with today is a low, single-story frame structure, substantially built and having from three of five rooms.

Two-room Houses—With camps located in remote districts and subject to the occasional visits of officials who are obliged to remain over night, it sometimes becomes necessary to provide for their accommodation. Fig. 2 shows a comfortable little house adaptable to such emergencies, which may be cheaply built and will accommodate four persons comfortably. It has a sitting room 9x12 ft. and a bed room 12x15 ft., the latter having a good roomy closet. Studs and rafters of 2x4 stuff are used throughout, drop siding on the sides, a shingle roof, and the interior lathed and plastered. Four spring-lock windows, 8x10 twelve light, are provided, and a single 2-ft. 6-in. by 6-ft. 6-in. outside door equipped with a good lock.

Fig. 1. A Commodious Superintendent's House

Three-room Houses—In Fig. 3 is shown an illustration of a neat and substanially built house of the three-room variety, the floor plan of which is shown in Fig. 10. There is always a certain demand for houses of this type, and mining towns are seldom built without including a certain percentage of these.

A house of the dimensions here shown provides ample room to meet the requirements of the small family, for which purpose it is intended. These overall dimensions are often cut down four or five ft., effecting considerable saving in construction and still being of sufficient size for ordinary purposes.

Two exterior doors, 2 ft. 8 in. by 6 ft. 8 in., are provided, one each for the kitchen and living room. Should it be desirable to have a porch at the rear, the kitchen door should be changed to the other side from the one here shown, which places it close to the corner, mak-

FIG. 7. FOREMAN'S HOUSE WITH HIP ROOF

FIG. 8. A SUPERINTENDENT'S OR FOREMAN'S HOUSE

FIG. 9. SUPERINTENDENT'S HOUSE WITH HIP AND DECK

ing the porch easier to support and providing more available wall space. Interior doors, 2 ft. 6 in. by 6 ft. 6 in., connect all adjoining rooms, and each room is provided with two double-sash, spring-bolt, 12x14, eight-light windows with the exception of the bed room which has three. Transoms are not ordinarily stipulated for miners' houses, but one should be provided for the front door.

In Fig. 11 is shown a plan of a three-room house of the smaller variety, but having a few additional conveniences. The total cost of this house would, under equal conditions, probably be about the same as for that shown in Fig. 10, and to the small family for which it is intended, would doubtless be more acceptable.

The kitchen is provided with a sink and drip board, items of small cost and no little convenience, and has also a commodious pantry. Off the bed room is a closet, and the front entrance has a 5-ft. 6-in. by 8-ft. porch which adds much to the appearance and has a real practical value, since the house has no entrance vestibule. A double-flue chimney is so located as to be accessible from all three rooms.

Four-room Houses. The four-room house is one of the most popular types met with, since it provides the maximum floor space with the minimum expenditure of labor and material.

In Fig. 4 is shown an example of the ordinary house of this variety, and in Fig. 12 a ground plan. These houses are commonly built from 24 to 28 ft. square, 26 ft. being a good average size. In the plan here shown the house has 28 ft. frontage and 26 ft. depth, which gives 1 ft. additional length to each of the rooms, over that obtained in the 26-ft. square house.

Houses of this variety are often constructed with the hip roof, as shown in Fig. 4 instead of the gable roof as shown on the five-room house in Fig. 5, with the mistaken view of securing economy of labor and material. In the hip-roof construction all the rafters are of variable length and require bevel cuts at one end, necessitating the careful attention of a competent carpenter to insure good results. The four sloping hips present difficulties in obtaining a weather tight joint and excessive waste of both labor and material occurs due to the variable lengths and bevel cuts necessary in both the sheathing and rafters.

These houses are ordinarily divided into four equal and separate rooms by partitions running through the center each way. In some instances a foot or two is taken from the bed rooms and added to the dining and living rooms, which is generally considered a good plan. With the hip roof some difficulties in the chimney construction occur when this is done, owing to the chimney not being in the center of the building, since it is usually desirable to have it readily available from each room and supported at the intersection of the partitions.

Five-room Houses—The five-room house is one of the standards in coal-camp construction, a certain percentage of these nearly always being included in the general scheme.

In Fig. 5 is shown a typical example of this class of house and in Fig. 16 is a ground plan of the same. This house is essentially the same as the four-room house with a lean-to addition at the rear, and much that has been said of the former will apply equally well to this.

Since these houses are, of course, intended for the larger families it is customary to make them amply large, not less than 26 ft. square for the main building, and 28 ft. being still better. The lean-to additions are ordinarily made 12x16 ft., the short dimension being placed perpendicular to the main building in order to provide a maximum slope with the minimum loss of head room. With the addition of the fifth room, another chimney becomes necessary, one with a small single flue being sufficient.

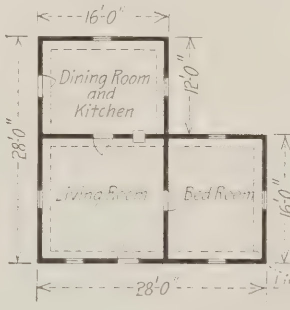

Fig. 10

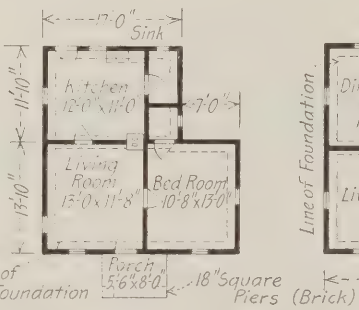

Fig. 11

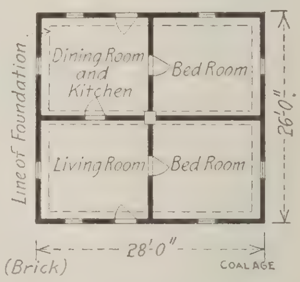

Fig. 12

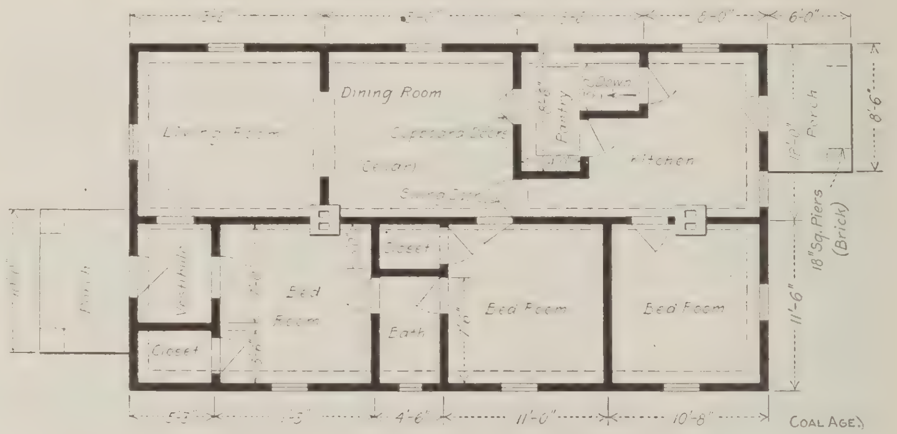

Fig. 13. Superintendent's or Foreman's House

Superintendents' and Foremen's Houses

The range for selection of houses of this class is unlimited, and, of course, dependent on the position of the individual for whom it is intended, and the policy of the company. They may be anything from a slight improvement on the ordinary five-room house to a large, commodious two-story building with all modern appurtenances. While a discussion of the latter variety will not be attempted, a description of a few typical examples of the former will be given.

A modest improvement on the average miner's house is shown in the illustration, Fig. 6. This is built along the lines of the usual five-room house, but finished up much better, and has an ordinary gable roof and a commodious porch. The interior is lathed and plastered, special single- and two-light windows are used for the front rooms, while large four-light windows are used in the others. Another house along the same lines, but having a hip roof and finished with drop, instead of lap siding, is shown in Fig. 7. This is a very neat, attractive and well-balanced type of house for moderate expenditures.

A more elaborate and substantially built house is shown in Fig. 8. The floor plan for one very similar to which is shown in Fig. 13. Hip-roof construction is used, in order to add to the appearance of the house, and both front and rear are provided with porches. A cellar is also included, access to which is obtained by stairs from the kitchen leading under the pantry. The main

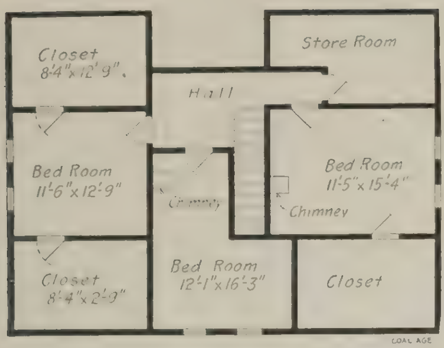

FIG. 14. SECOND FLOOR, TWO-STORY HOUSE

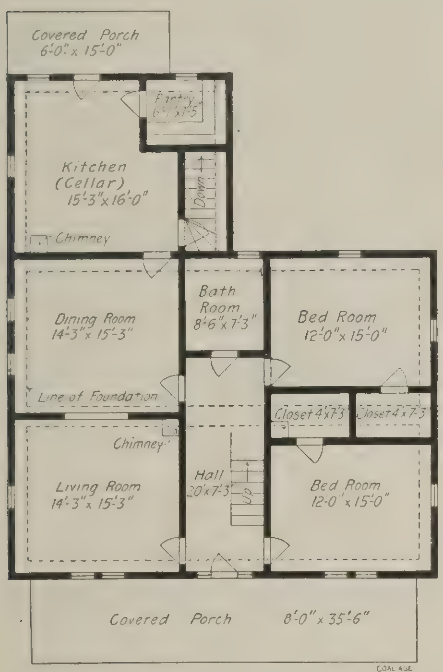

FIG. 15. FIRST FLOOR, TWO-STORY HOUSE

FIG. 16. FIVE-ROOM HOUSE

pantry door leads to the kitchen and cupboard doors also give into the dining room. The number and distribution of the remaining rooms is clearly shown in the plan. Another house of a very similar design but more elaborately finished is shown in Fig. 9. This house has a hip roof with a deck and a number of minor details which adds much to the appearance of the completed structure.

A well balanced, good appearing and commodious house of the two-story variety is shown in Fig. 1, floor plans of which are shown in Figs. 14 and 15. The usual gable roof is used, with a dormer window in front which gives an additional room on the second floor, and relieves the straight lines of the house. A cellar is provided under the kitchen, and the latter has a large roomy pantry. The bath room is on the first floor, which also has a large hall containing the stairs leading to the second floor. The ceiling on the first floor is 9 ft. high, and the interiors finished in lath and plaster, with appropriate base boards and picture mold. The length of studs used is 14 ft., which makes the hight of the walls under the eaves on the second floor about 4 ft. The partitions for the second-floor rooms are placed back far enough from these low walls to get an even 8-ft. ceiling and the remainder of the space utilized as closets and store rooms.

Mining Law in Virgina

The following provisions cover all the mining regulations in force in the State of Virginia:

To secure operatives and laborers engaged in and about coal mines and manufactories, the payment of wages at regular intervals and in lawful money.

(1) All persons, firms, companies, corporations or associations in this Commonwealth engaged in mining coal, ore or other minerals, or mining or manufacturing them, or either of them, or manufacturing iron or steel, or both, or any other kind of manufacturing, shall pay their employees as provided in this act.

(2) All persons, firms, companies, corporations or associations engaged in the business aforesaid shall settle with their employees at least once in each month, and pay them the amounts due them for their work or services in lawful money of the United States, or by the cash order, as described and required in section three of this act; provided that nothing herein contained shall affect the right of an employee to assign the whole or any part of his claim against his employer.

(3) (As amended by chapter 118, acts of 1887-'88.) From and after the passage of this act, it shall not be lawful for any person, firm, company, corporation or association engaged in the business aforesaid, their clerk, agent, officer or servant in this State, to issue for payment of labor any order or other payment whatever, unless the same purports to be redeemable for its face value in lawful money of the United States, made payable on demand, and without condition, to employee or bearer, bearing interest at legal rate, and redeemable by the person, firm, company, corporation or association giving, making or issuing the same; and any person, firm, company, corporation or association engaged in the business aforesaid, their clerks, agents, officers or servants, who shall issue for payment of labor any paper or order, other than the one herein specified, in violation of this section, shall be guilty of misdemeanor, and upon conviction shall be fined in any sum not exceeding one hundred dollars, in the discretion of the court.

(4) From and after the passage of this act, it shall be unlawful for any person, firm, company, corporation or association engaged in mining or manufacturing, either or both, as aforesaid, and who shall likewise be either engaged or interested, directly or indirectly, in merchandising as owner or otherwise, in any money, per centum, profit or commission arising from the sale of any such merchandise, their clerks, servants, officers or agents, to knowingly and wilfully sell, or cause to be sold, to any employee any goods, merchandise or supplies whatever, for a greater per centum of profit than merchandise and supplies of like character, kind, quality and quantity are sold to other customers buying for cash and not employed by them; and shall any person, or member of any firm, company, corporation or association, his or their clerk, agent or servant, violate this section of this act, they shall be guilty of a misdemeanor, and upon conviction shall be fined in any sum not exceeding one hundred dollars, in the discretion of the court.

Survey Stations Underground

In surveying a fairly thick vein in a dry mine, spad stations usually give better results than hole stations drilled in the roof, inasmuch as the variation of the plumb-bob string held in the hole station is greater than when held from a spad station. When a spad is used as a station, it is so driven into the plug that the hole in the spad takes a slant position so that when a string is hung through the hole it always hangs in the same position. Where the roof is low, spads should not be used for stations as they are likely to be disturbed.

Anthracite and Bituminous Mining

By Eli T. Conner*

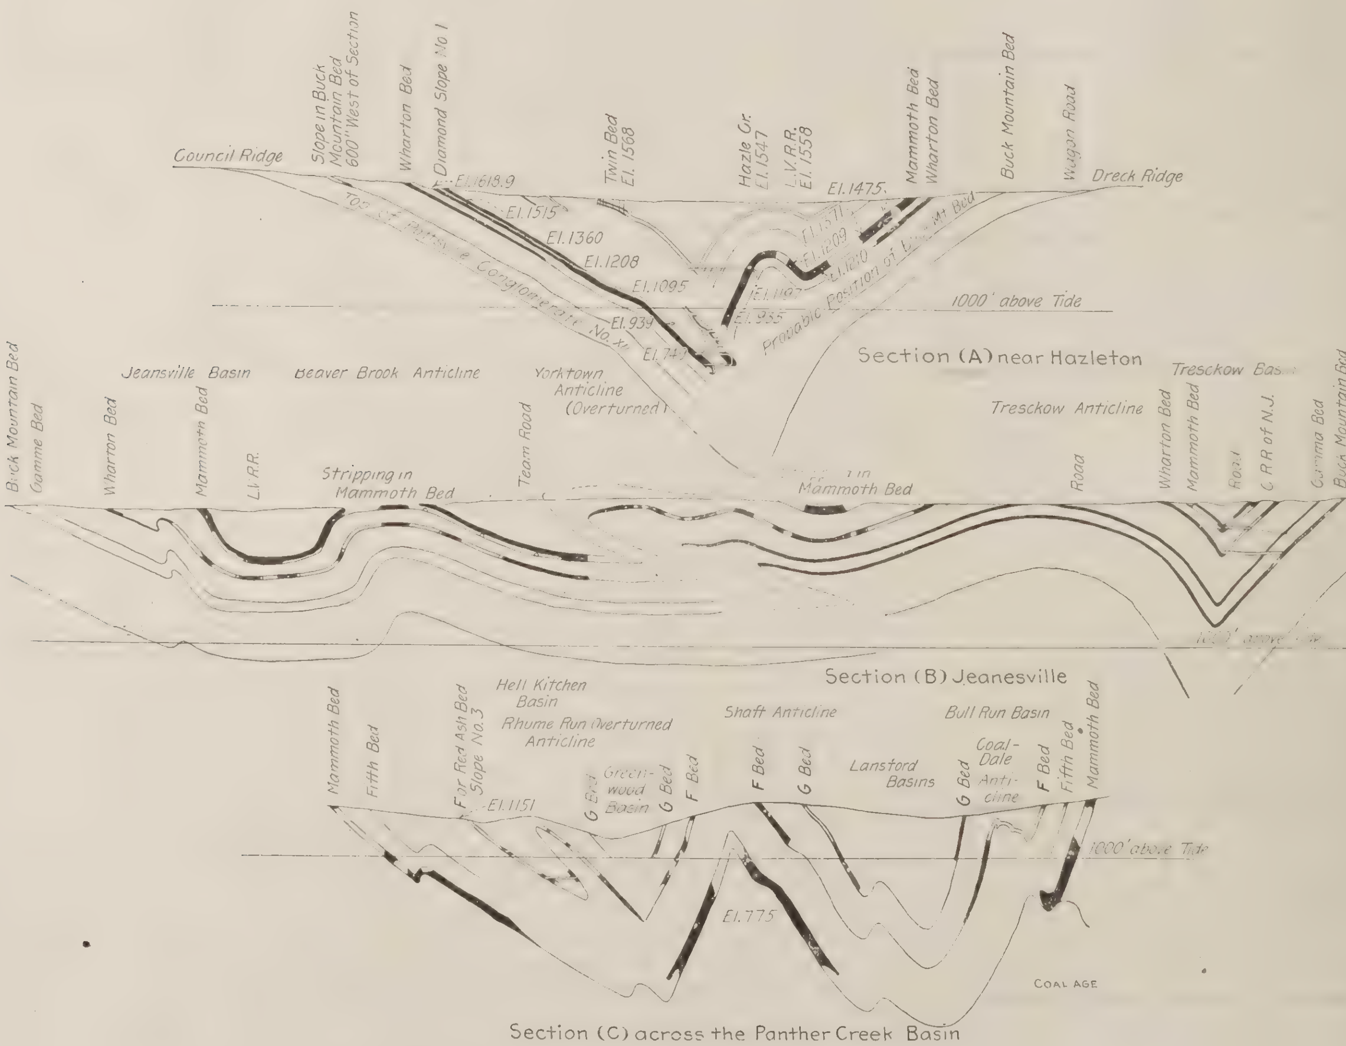
A description of the methods and measures in the Eastern Middle or Lehigh Region where the pitches are so severe that the coal frequently breaks up and runs without mining. The second of a series of articles by Mr. Conner.

It is purposed in this article to discuss the geology and economic development of the Eastern-Middle or Lehigh region. The former article, which appeared in COAL AGE, Oct. 14, treating of mining conditions in the northern anthracite field, was illustrated by cross-sections, which should be compared with the three cross-sections accompanying this article in order that the reader may appreciate the widely different conditions met with in the Lehigh region. It will be noted that the main basins in the Lehigh district are deep and distorted, causing excessive pitches; consequently the methods of attack, development and operation must differ widely from those of northern anthracite-field practice, and must necessarily require quite different training to develop competent miners, foremen and managers. It has been found by experience that men whose early training has been in the northern anthracite field do not generally make competent employees in the Lehigh or southern regions and vice versa.

The Mammoth Bed and Its Extraction

The principal seam of coal found in the Lehigh region, as elsewhere, is the great Mammoth bed, which corresponds to the Baltimore seam in the northern field. This bed in the Lehigh region varies from 24 to 50 ft. in thickness, the average being about 30 ft. Most of the early mine development was made on the Mammoth seam. The methods of development and mining that were inaugurated many years ago have been continued with comparatively slight changes. These methods are well illustrated by cuts accompanying this article, taken from the report by H. H. Stoek, contained in the 22d annual report of the United States Geological Survey, which illustrate gangway and airway, and chamber workings in thick and thin seams on steep pitches.

It will be noted that where the chambers are worked "full," the entire content of the bed whatever it may be, together with any "slab," "clod," or "loose top rock," must be drawn out of the chute at the bottom of the chamber, into the mine car, as there is very little opportunity to separate the impurities from the good coal in the mine. This is not an unmixed evil, as it avoids the great waste, referred to in the article on the northern anthra-



COAL BASINS IN THE EASTERN MIDDLE ANTHRACITE FIELD

*Mining engineer, Real Estate Trust building, Philadelphia, Penn.

cite field, of throwing into the gob doubtful and off-color benches of coal, which, if sent outside to the breaker, as is the case where coal is loaded from running chutes, can be inspected and some part at least of the doubtful coal saved for the market. In other words, it is not left to coal is shot off the solid, but in the Mammoth seam it frequently happens that after the chamber has been developed so that the whole seam is cut from floor to roof, it becomes impossible to control the chamber by reason of the coal "running." When this happens, the miner continues down. This may, perhaps, occur before all of the solid coal has been recovered. There is no possible way of ascertaining whether or not, all of the coal that should come out of a given chute or series of chutes has been recovered, consequently it is necessary to handle the rock that

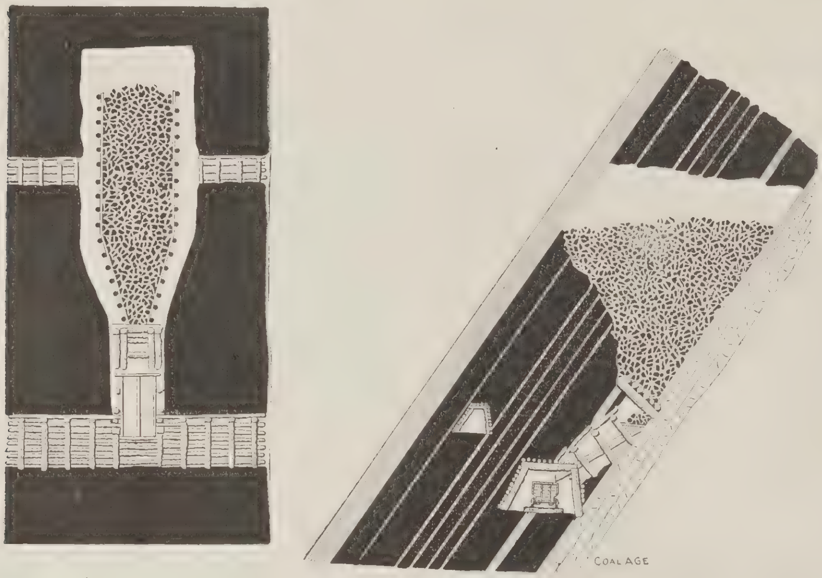
the judgment of the individual miner or his laborer to determine what is or is not marketable coal.

The "Running" of the Mammoth Bed

In driving the chutes and chambers, as shown by the cuts before referred to, the to draw coal out of the chute so long as it will "run." It frequently happens that when one or more chambers break loose in this manner, not only the coal directly in line with the chutes, but also the pillars between adjoining chambers, run out, permitting the roof rock to come comes when a fall occurs, until the foreman feels convinced that no more coal can be recovered from that chute. In this way enormous quantities of rock are loaded in the mine cars, transported to daylight and dumped on the waste bank.

SLICING METHOD OF MINING THICK BEDS

It is well known that this method of mining very thick beds of coal standing on steep pitches oftentimes results in the recovery of a lamentably small percentage of the original content. Earnest thought and effort have been put forth by able managers to devise better methods of winning these thick beds of coal, but very little change resulting in improved recovery has been made since the early days.



HEAVILY PITCHING BREASTS ON MAMMOTH BED HAZELTON

American engineers have been much interested in reports of the successful mining of thick beds of coal in Europe by what is known as the "slicing method," by which the coal is extracted in slices from the bottom upward, each slice being about 6 to 8 ft. thick, and the space from which it is removed being filled with flushed sand or other material before the next slice is extracted. This operation is reported to result in the recovery of practically all coal, with comparatively slight subsidence of the overlying rock.

As a report is shortly to be made on this subject by a commission recently sent to Europe by the Mining Bureau of the United States Government, no further description of it is necessary here. The forthcoming report will be of great interest to engineers familiar with the methods pursued in mining thick and steep beds in the Pennsylvania anthracite field.

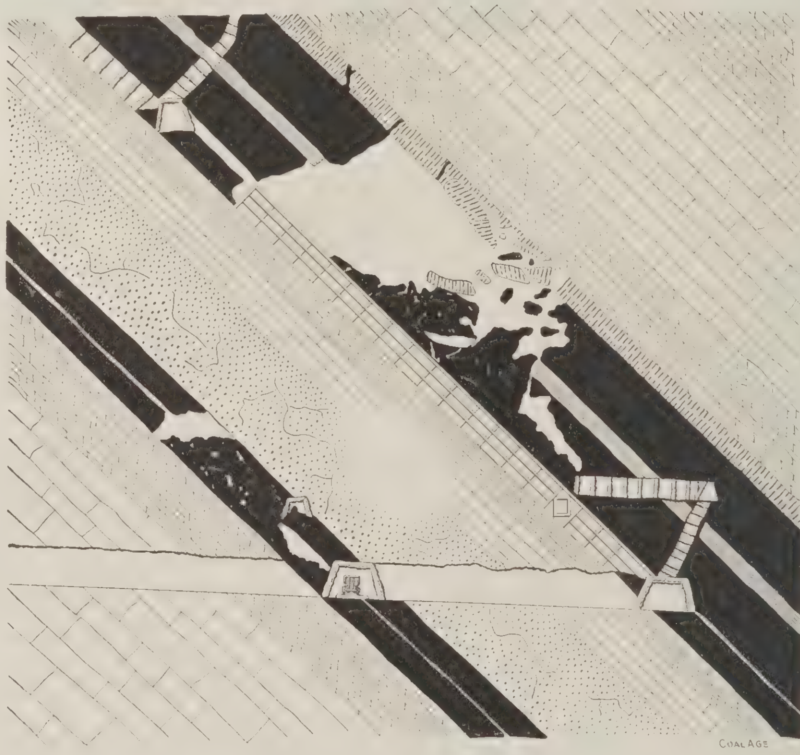
THE NEED FOR LARGER CONSERVATION

The great loss of coal due to the methods and conditions to which reference has been made, was very carefully investigated and reported upon by the Anthracite Coal Waste Commission, composed of the late Eckley B. Coxe, William Griffith and the late Heber S. Thompson, who reported to the Governor of the State of Pennsylvania in 1893. This commission estimated that in the average mining of the Mammoth and other beds where the pitches are steep, not over 40 per cent. of the original content in the ground had up to that time been recovered. This represents an appalling irrecoverable loss of exceptionally high-grade fuel. Very little, if any, improvement in recovery has been made since that report was filed, excepting that in recent years buckwheat Nos. 1, 2 and 3 are now being marketed. The estimates mentioned included pea and buckwheat No. 1, but not the two lower grades.

The loss of coal in the Mammoth seam is not the only damage done, as in most cases in the earlier days of the industry no attention was paid to thin and so called inferior seams of coal overlying the Mammoth, which, in many instances, have been practically destroyed by the dropping of the underlying strata, due to caving of openings in the Mammoth bed. This destruction of overlying beds was, of course, more pronounced years ago than in recent years, because more attention has been given to the conservation of the marketable coal in all beds, even in those as thin as 30 inches.

STRIPPING METHODS FURNISH COMPLETE CONSERVATION

It will be noted by the cross-sections that there are many instances where the beds of coal come close to the surface at the "spoon" ends of basins, the marginal outcrops and on the crests of anticlinals. In such cases it has been found profitable to strip off the overlying earth and rock, exposing the seam of coal, which can then be quarried in open-cut mining. The first work of this character on an extensive scale was undertaken by Ario Pardee, at his Hollywood colliery, near Hazleton, Penn., in 1881. This work was commenced by the late Capt. William I. Conner, my father, who introduced the first steam shovel used for this purpose in the anthracite field. Since that time extensive stripping operations have been carried on in the Lehigh region with satisfactory results. It was then the opinion of engineers and operators that 1 ft. of overburden could be removed with profit to effect a recovery of 1 ft. in vertical thickness of coal seam, even though the



METHOD OF WORKING CONTIGUOUS SEAM THROUGH HORIZONTAL ROCK TUNNEL

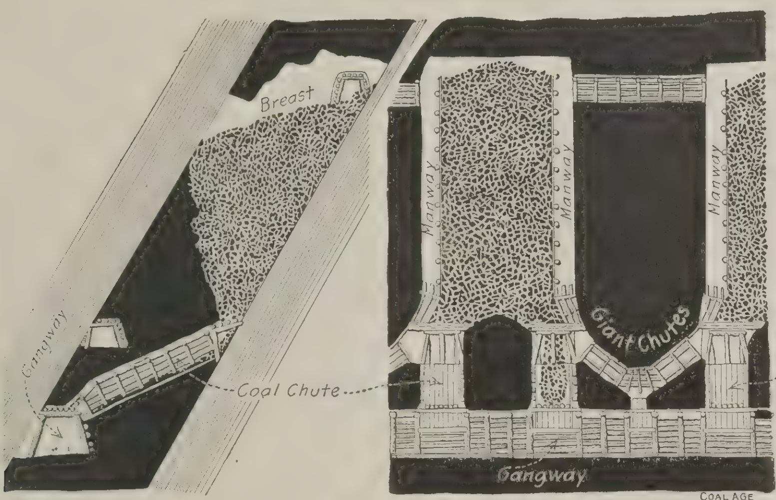
coal bed had been partially mined by underground methods. This relative proportion has been greatly changed during the past 10 or 15 years, until as much as 3 ft. of overburden, 60 per cent. of which is rock, has been removed for the recovery of one vertical foot of coal bed.

On large operations, the cost of this stripping work has been done within my knowledge for 18c. per cu.yd. of earth, and 35c. to 40c. per cu.yd. of rock. While stripping means a large outlay before much return can be secured, it permits the recovery of all the coal, with cheap methods of mining and handling. In order to illustrate the stripping methods, several photographs are introduced showing typical operations.

Slopes in Coal vs. Shafts with Tunnels in Rock

The early developments in the Lehigh region were by slopes sunk directly to the true dip on the bed, usually following the floor or footwall. From these slopes levels were turned on the strike of the seam, usually at intervals of about 500 ft., as measured on the pitch. This former method of development was quite successful, in most cases, for the operation of four or five lifts, but beyond that, it was found as years went by, that the cost of maintaining the slopes and levels was excessive, due to the very large amount of extra heavy timbering that was required to maintain the openings.

In recent years important developments have been made by sinking shafts of large area in the centers of the basins, with the long axes of the shafts parallel to the axes of the synclines. From these shafts, levels are turned off in rock on both sides. These levels are placed so as to intersect the old levels formerly driven from the slopes, and are generally about 400 ft. vertically apart. A notable instance of this type of development, which has worked out quite successfully, is the Hazleton shaft of the Lehigh Valley Coal Company.



Double Chute Breasts, Anthracite Region

The advantages of this method of development are that all the levels to the main outlet are in rock, and are consequently much easier of maintenance, besides which the main haulage roads can be materially shortened and upper levels, when the coal is exhausted, can be abandoned more readily than by the slope method. Another advantage is the ability to concentrate the drainage and centralize the pumping plant. This is quite important as the quantity of water to be handled is, in this region, greatly in excess of the average amount in the northern anthracite field.

American Mining Congress

The American Mining Congress will meet at the Hotel La Salle, Chicago, Ill., October 24 to 28, both dates inclusive, for its 14th annual session. The following delegates have been appointed by the President: John Hays Hammond, Washington, D. C.; George Otis Smith, Director of the U. S. Geological Survey; Robert N. Dickman, Chicago, Illinois; J. Parke Channing, New York City; W. R. Ingalls, New York City; Frank H. Crockard, Birmingham, Ala.; F. W. McNair, Houghton, Michigan; C. H. Lindley, San Francisco, Cal.; Dr. J. A. Holmes, director of the Bureau of Mines; George S. Rice, Pittsburg, Penn.

It is expected that President Taft will address the congress on the closing day, being accompanied by the Secretary of the Interior, Walter L. Fisher, and director of the Bureau of Mines, Dr. J. A. Holmes. John Hays Hammond, consulting engineer, President B. F. Bush, of the Missouri Pacific Railroad, and Governors Spry, of Utah, Carey, of Wyoming, Hawley, of Idaho, and Sloan, of Arizona, are expected to be present.

National Secretary James F. Callbreath, Jr., announces the following as the subjects with which the convention will principally occupy itself:

1. The prevention of mining accidents.
2. Compensation for the victims of mining accidents.
3. The prevention of waste of natural resources and the conservation of energy.
4. The general problems of the bituminous coal-mining industry as intensified by the demand for better protection to miners and the conservation of fuel resources.
5. The Alaskan question.
6. The public-lands questions of the West as they affect the mining industry.

A New Colliery near Crows Nest Pass

The Hillcrest Collieries at Hillcrest, Alberta, have, during the past year, been developing a large coal measure in the Crows Nest Pass territory. The location of their mine is known as Hillcrest, about two miles from the famous town of Frank. The past year has been spent in development work; an expensive rock tunnel has been driven to the coal, and many entries driven in the seam. An extensive electric haulage system is being installed, and the company has just placed an order with the Ottumwa Box Car Loader Company of Ottumwa, Iowa, for a large steel tipple.

The coal will be brought along the mountainside on a tramway, received at the upper end of the tipple, and then carried by a conveyer system down the mountainside, over 600 ft., where it will be loaded into railway cars, or dumped into storage bins, from which it may be drawn later, as convenient.

The coal is of the famous Crows Nest Pass grade, and the ultimate capacity of the mine will be 3000 tons per day.

Watering a Mule

Mules should be watered three times a day when in the stable; when working, more frequent watering is desirable. Small quantities of water taken at short intervals are preferable to heavy drafts three times a day. No harm is done by watering mules or horses when warm if they are allowed to take only six to ten swallows of water. It would be well to follow this, when the animal is being stabled, by a pound or two of hay. Then give him a rest of an hour before receiving his regular ration. If water is given to him after this hour of rest, he will in all probability refuse it or will drink sparingly.

A little water will not hurt a warmed-up mule, but the condition the animal is in induces him to drink to excess and it is mainly in that excess that the danger lies.

The Castle Valley Coal Company

By Benedict Shubart *

Description of a mine that is typical of the far West. The seam is nearly flat and varies in thickness from 23 to 35 ft. There are two main-haulage entries, and each side of the mine is handled as a separate operation.

Situated in the beautiful Cedar Creek cañon, in Emery county, practically at the edge of the Utah desert, lie the mines of the Castle Valley Coal Company. For the past 30 years the farmers and precious-metal miners in the vicinity have been digging coal from this unusual seam, driving their teams into the opening, mining the coal by hand and loading it into their wagons. A cavern about 100 ft. long, 200 ft. wide and 35 ft. high has thus been made, and all these years this opening has stood without a prop and without any sign of caving.

Several years ago, James H. Mays and Moroni Heiner, of Salt Lake, visited this country and acquired 4000 acres of land, which are now owned and operated by the Castle Valley Coal Company. Mining operations were commenced two years ago and the coal has now been in the market for 15 months.

The mines are situated about 20 miles from the town of Price, a point on the Rio Grande railroad, where the company owns extensive yards and trackage, and lie a little west of south. In connection with the opening of the mine, it was necessary to build a railroad over the rugged foothills to the mines, six miles from Castle Junction, where the Castle Valley railroad meets the Southern Utah railway. The topography of the country made the building of this road exceedingly difficult, and the road as now built has the disadvantage of grades as heavy as 5 per cent., both with and against the loaded trains. It is probable that within the next year, this line will be abandoned and a road constructed practically direct from Price up to the mine, securing a favorable grade all the way.

*Engineer, Boston building, Denver, Colo.

Coal Seam Is 35 Ft. Thick

The coal seam is a continuation of the bed now being worked at Hiawatha by the Consolidated Fuel Company. It is, however, much thicker, reaching a thickness of 35 ft. in places. The roof is quite irregular although good from the mining standpoint and the coal varies in thickness from 23 ft. up to 35 ft. The floor is of sandstone and is quite even. The coal pitches approximately 1 deg. west, not much more than enough for proper drainage, although the water question has not yet proved troublesome. In fact, just about enough water has been developed to keep the haulageways properly wet. No props are necessary at any point in the mine.

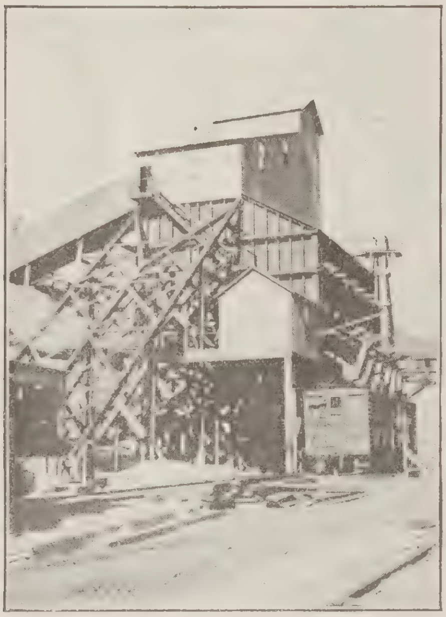
In addition to the seams now being worked, there are at least four other beds which have been proved, of which two can easily be worked at the present time. The second thickest seam is 10 ft. in thickness and contains a good grade of coking coal. In the main seam, the coal does not show any marked slips. It is massive in its structure, is hard, stands handling and storage well, and while it is rather hard coal to mine, yet it shows a good percentage of lump coal, and quite a small percentage of slack.

The company reports the following analysis of its coal, although it is probable that the run-of-mine will average somewhat higher in ash:

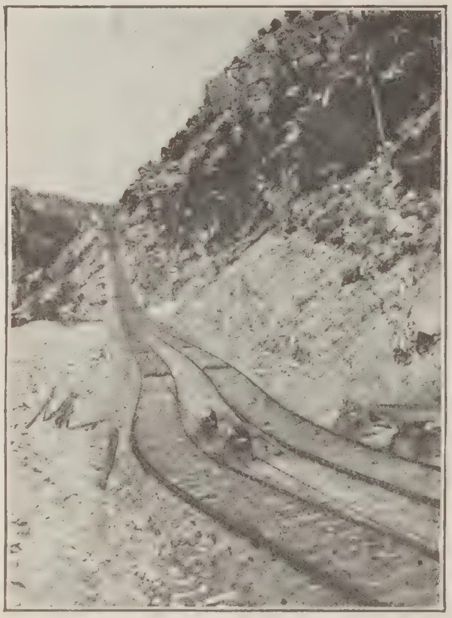
ANALYSIS OF UTAH COAL

Moisture	3.76
Ash	3.50
Volatile combustible matter	39.89
Fixed carbon	52.85
Sulphur	0.52
Phosphorus	none

The mine lies 8000 ft. further up the cañon than the tipple, and the two are connected by a gravity incline with grades varying from 25 per cent. at the top to less than 4 per cent. at the bottom. The trips are lowered by a pair of Stine sheaves and are landed at a point about 800 ft. from the tipple. On account of the heavy grade at the head of the incline, it is necessary to get a good running start for the trip, making it a rather dangerous incline to operate. It is probable that it will be necessary to install a different type of sheave so as to secure better control of the trip. The cars are taken from the incline to the tipple by means of a 12-ton Goodman single-motor locomotive.



Side View of Tipple Looking Up the Canon



Showing the Incline and Rope Haulway

Front of Tipple, Showing Loading Chutes

The main-track gage is 48 in. Steel cars holding about five tons net of coal are used. About 100 of these cars are now in service.

There Are Two Main-haulage Roads

The mine is laid out with two main-haulage entries, the return airway being

between the two main roads, each side of the mine being handled as a separate mine. The main-haulage roads are used as air intakes and a 7½-ft. Stevens fan is installed outside about 20 ft. out of line of the return airway. This is driven by a 100-h.p. variable-speed direct-current motor furnished by the Ridgway Dynamo and Engine Company.

Mining is on the room-and-pillar system. Rooms are driven about 25 to 30 ft., wide with 30-ft. pillars. The good roof and floor, together with the physical condition of the coal, make it satisfactory to attack the coal in almost any direction. The rooms are driven 400 ft. long. A parting about 9 ft. above the floor permits taking down this amount of coal and the roof coal and pillars are drawn retreating as the entry is abandoned.

View of Tipple and Power House of Castle Valley Coal Company

Another View of Surface Plant when Looking Up the Canon

Castle Valley Coal Company's Power House and Slack Chute

The Company Store Is a Substantial Structure Built of Native Rock

A large portion of the coal and all the entries are cut by means of Goodman chain-breast mining machines. The machines are manned entirely by Japanese crews who operate the cutters with considerable skill. Machine mining has been quite successful.

Electric locomotive haulage is used throughout and there are few horses in the mine. For the main-haulage work, the twelve-ton single motor type of locomotive has been selected. For gathering, six-ton locomotives are now in use but an eight-ton locomotive is now being placed in the mine, and in view of the very large cars in use, better service is anticipated from it. These large cars operate against horse haulage and in favor of electric haulage, so that it is considered that the system of locomotive gathering that is here employed is well adapted to this mine.

The power plant shown in the accompanying illustration is placed opposite the tipple. The building is a substantial one of steel and native stone and contains three 100-h.p. return-tubular boilers which furnish steam for a belt driven 200-kw. Goodman generator driven by a Ridgway center crank engine. Practically none of the current is used at the tipple except for lighting. The entire current is carried at 250 volts up to the mine 8000 ft. above. This makes a poor and uneconomical transmission and plans are under way for the alteration of this plant into 2300-volt, three-phase, sixty-cycle alternating-current plant with a motor generator at the mine to furnish the necessary direct current. All the auxiliaries about the tipple are driven by steam engines. Coal is taken from the tipple to the boiler-house by means of a conveyer, thus providing coal for the boilers without any extra labor costs.

Details of the Tipple

The tipple is a peculiar design and consists of two distinct divisions. The original tipple is shown in the photograph. The coal is dumped at a point 90 ft. from the tipple and is carried up into the tipple house by means of a corrugated apron Link-Belt conveyer which feeds the coal evenly upon the screens. The shaker screens form 7 different products which are delivered into 7 different 100-ton bins, providing storage.

This system did not work out well, the coal was badly broken in handling and it was found impossible to load any reasonable amount of coal through these bins. This portion of the tipple was, therefore, abandoned except as an auxiliary, and a new set of screens of the usual type were installed at the upper end of the old structure, loading coal direct onto three tracks. The coal is fed onto the screens by the apron conveyer just as before, but when necessary to make more than three products, the screened coal is elevated and rescreened over the old set of shaking screens, dividing the screened coal into egg, nut coal, pea coal, and slack or rather dust. This dust is usually wasted, as there is very little market for it. The lump coal is loaded direct into cars while the screened coal consisting of the egg and smaller sizes is elevated 80 ft. by a massive Link-Belt continuous bucket elevator and discharged onto the old shaking screens, where it is rescreened as above described.

A portable Christy box-car loader was originally purchased in order to move

from chute to chute and load the coal into box-cars. This has now been permanently installed so as to take the coal from the new screens.

At present, approximately 1000 tons of coal per day are shipped. The mine is gradually being opened up so as to secure an output of about 4000 tons per day. This tonnage can be handled easily over the present incline.

The coal is handled by the Western Fuel Company, of Salt Lake City, and marketed throughout Utah, Idaho and the Pacific Coast. There has been no difficulty in disposing of the entire mine tonnage.

The town of Mohrland has been well laid out with houses of attractive type, streets straight, clean and well lighted at night.

The accompanying photograph shows a unique type of store. It is unquestionably a striking and handsome building and was built entirely of native stone quarried in the immediate vicinity. The left-hand wing is used for the mine office.

The active officers of the company are: J. H. Mays, president; Moroni Heiner, vice-president; Archie J. Orem, assistant general manager; and these, with J. G. Berryhill, W. W. Armstrong and W. C. Orem, constitute the active management.

National Safety Demonstration

Arrangements have been practically completed by the Bureau of Mines for the National Mine Safety Demonstration which is to be held in Pittsburg on Aug. 31 under the auspices of the Bureau of Mines, the American Red Cross Association, and the Pittsburg Coal Operators Association. A request has been made of the Pittsburg operators to declare Oct. 31 a holiday in the mines of the district. It is believed that this demand will also be made in West Virginia, Virginia, Ohio, Illinois, Indiana. Other States further away will send large delegations of miners and first-aid teams.

It is expected that the American Mining Congress which is to meet in Chicago, Oct. 24 to 28, will go almost in a body to Pittsburg to attend this demonstration.

Already more than half a hundred teams from as many mines throughout the country have entered the life-saving exhibition, one team signifying its willingness to come all the way from Roslyn, Wash., to show its skill. Among the teams that have entered are the Berwind-White Coal Mining Company, Windber, Penn., four teams under the direction of General Superintendent W. R. Calverley, No. 1 in charge of Captain William Brownlee, No. 2 in charge of Captain George Grove, No. 3 in charge of Captain J. C. Nedrow, No. 4 junior squad, Captain Edward Greyback; Cabin Creek Y. M. C. A. team, Charleston, W. Va., in charge of T. J. Robson; the Consolidation Coal Company, Maryland and West Virginia, two teams, No. 1 in charge of H. V. Hesse, superintendent Georges Creek division, and No. 2 in charge of E. B. Moore, chief engineer of the Fairmont division; the Delaware, Lackawanna & Western Coal Company, Scranton, Penn., two teams, No. 1, the Brisbin colliery team under Captain John Pierce, and No. 2, the Woodward colliery team under Captain Benjamin Lewis; Dunbar Furnace Company, Dunbar, Penn., one team in charge of Stewart B. Marshall, general superintendent; Ellsworth Collieries Company, Ellsworth, Penn., three teams, in charge of W. A. Luce, assistant general manager, No. 1, Captain E. C. Roberts, No. 2, Captain Fred Gulick and No. 3, Captain George Lindsay; Lehigh & Wilkes-Barre Coal Company, Wilkes-Barre, Penn., one team, in charge of C. F. Huber, vice-president and general manager; Lehigh Coal and Navigation Company, Lansford, Penn., one team, in charge of Baird Snyder, Jr., general superintendent; Lehigh Valley Coal Company, Wilkes-Barre, Penn., two teams, one representing Derringer colliery, under W. H. Davies, division superintendent, Hazleton division, and the other representing Centralia mines, under J. M. Humphrey, division superintendent, Centralia division; Miller Coal Company, Portage, Penn., one team, under J. H. Buckwalter, superintendent; Northwestern Improvement Company, Roslyn, Wash., one team, in charge of C. R. Claghorn, general manager; Oliver & Snyder Steel Company, Uniontown, Penn., one team, in charge of F. C. Keighley, general superintendent; Pennsylvania Coal Company, Scranton, Penn., one team in charge of Captain W. A. May, general manager; Parrish Coal Company, Plymouth, Penn., one team in charge of W. G. Thomas, general manager; Philadelphia & Reading Coal and Iron Company, Pottsville, Penn., one team in charge of George Richards, general manager; Pittsburgh-Buffalo Company, Marianna, Penn., one team in charge of S. C. Reynolds, superintendent; Pittsburgh Coal Company, Pittsburg, Penn., five teams in general charge of G. W. Schluederberg, general manager, No. 1, McDonald district, Superintendent L. C. Sarver, No. 2, Finley district, Superintendent James Porter, No. 4, Carnegie district, Superintendent H. Cattley, No. 5, Whitsett district, Superintendent W. Kelvington; Pittsburgh Railroad and Coal Company, Pittsburg, Penn., one team in general charge of W. W. Keefer, president; Portage Coal Mine Company, Portage, Penn., one team in charge of H. A. Tompkins, superintendent; Republic Iron and Steel Company, Republic, Penn., one team in charge of W. H. E. Royce, general superintendent; the Rochester & Pittsburgh Coal and Iron Company, Punxsutawney, Penn., one team in charge of W. O. Calloway, general superintendent; Spring Valley Coal Company, Spring Valley, Ill., one team in charge of J. M. Luther, assistant to the general manager; Stearns Coal and Lumber Company, Stearns, Ky., one team in charge of J. C. Butler, manager; Sunday Creek Mining Company, Poston, Ohio, one team in charge of Edward Coll, president; Susquehanna Coal Company, Wilkes-Barre, Penn., one team in charge of R. A. Quinn, manager; Tennessee Coal, Iron and Railroad Company, Birmingham, Ala., one team in charge of Edward Coxe, general superintendent; Tower-Hill Connellsville Coke Company, Uniontown, Penn., one team in charge of L. W. Fogg, general manager; and the Stag Cañon Fuel Company, Dawson, N. M., one team.

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROB'T MCKEAN, Sec'y.

505 Pearl St., New York.
6 Bouverie St., London, E. C.
Unter den Linden 71, Berlin.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of COAL AGE, *we will print 5000 copies. No copies will be sent free regularly. There will be no back numbers. The figures which will be shown here each week will represent live, net circulation.*

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

COAL AGE

Reducing Mortality

A number of important subjects now absorb the attention of thoughtful men. However, no problem is more deserving of careful study than the saving of human life. Conservation of resources, no doubt, will benefit posterity, but conservation of health and limb among the "daddies" of posterity, will be preservation of the nation's most valuable asset.

The mine-safety or first-aid convention to be held in Pittsburg, Oct., 30 and 31, under the auspices of the U. S. Bureau of Mines assisted by the Red Cross, promises to be a meet of national importance. Enthusiasm is abundant, and never was interest in such an affair more widespread. Large coal companies in practically every field are sending their quota of trained rescuers, and the encouragement and general recognition being accorded the first-aid movement is sure to result in much good to coal men.

Not only will benefit come from within, but there will accrue profit to the industry from educating the public. It will be an enlightenment to those unfamiliar with coal mining, to know the universal attention being accorded the humane work of safeguarding the men who produce coal.

The object of the Pittsburg meeting is not only the furtherance of first-aid work, but the diffusion of advanced ideas concerning all effort to safeguard coal miners. The government experimental mine and all details of the research work being conducted by the Bureau of Mines, will be fully explained. Let everyone who can, turn out, and help show the outside public that the first and foremost desire of the American coal industry is safety in mining.

The Coal Land Inquiry

One of the most extensive investigations into coal lands and the conditions under which they may be taken into private ownership, their relation to the Government, and the problems relating to the leasing of such lands or the granting of their use on a royalty basis, will be undertaken within a comparatively short time at Washington. The return of Secretary Fisher and Director Holmes from Alaska, will supply expert evidence from the standpoint of the Government on this subject, in addition to the large mass of material which is already available. The inquiry will be started by the committee on Controller-Bay lands which was appointed under House Resolution No. 103 last session "to investigate the expenditures in the Interior Department."

While the investigation was nominally begun for the purpose of studying the Controller-Bay lands, as the title indicates, and while the further progress of it was somewhat rambling, owing to the introduction of political charges, the fact remains that the substance of the remainder of the inquiry will probably be the natural resources of Alaska and the best way of handling them. Chief among these will be the question of coal lands and their use. It is likely that the investigation will not be solely confined to the special committee headed by Mr. Graham, but will also be carried on by the public-lands committees of both Houses of Congress, the result being to bring forward public-land legislation relating to Alaska for early action.

If present plans work out as expected, the result of the investigation and of the work of the session will be that of settling the future of Alaska so far as the use of mineral resources is concerned.

At the public-lands convention in Denver, notwithstanding the opinion of those present that the lands should be disposed of to individuals, or placed under the care of the separate States, President Taft distinctly advocated the adoption of the leasing system; the same that he has urged on previous occasions in messages and in conversation with members of Congress. So-called "progressive" members of Congress think that in order to guarantee the success of any plan for leasing coal lands in Alaska, the Government must provide the transportation by building a railroad through the coal area and guaranteeing absolutely equal terms of transportation over i

Only a few progressives are willing to advocate Government operation of Alaskan mines, although there are some who say they believe in it as a last resort. What does seem to be true is that the feeling on the subject of land legislation, particularly coal-land legislation, is growing strongly favorable to a much greater degree of stringency in the control of such lands, and much more strongly unfavorable to the passage of the lands into private ownership upon the same basis which has existed heretofore, or one analogous thereto.

It is already plain that there will be sharp controversy during the coming winter concerning the extent and value of the coal deposits in Alaska. Secretary Fisher has returned with the opinion that the value of the lands has been greatly overestimated. It is supposed that this will be concurred in by Director Holmes. Should that be the case, a good deal more detailed information is likely to be sought by Congress with reference to the matter.

The Graham Committee has already received testimony on that subject from Alfred H. Brooks, the geologist in charge of the division of the Alaska mineral resources in the Geological Survey. He has informed the committee that according to the estimate of a number of mining engineers, the coal in the field amounts to 500,000,000 tons. This was coal that could be brought out on grade, being above water level. His own estimate was that, including the coal present down to a depth of 3000 ft., several billion tons were available. If Secretary Fisher should differ from this estimate or from that of the other mining engineers who went to Alaska on behalf of some of the coal-land claimants, turned down by the Interior Department during the past summer, he will undoubtedly be called before the committee and will be asked to testify carefully concerning the character of his information. It is not likely that a reduction in the estimate of value will, however, alter the disposition of Congress in regard to stringent legislation concerning its use under such method of exploitation as may be determined upon.

The present plan is to resume the hearings before the Graham Committee shortly before the end of the current month. They are expected to continue more or less steadily through November. Louis D. Brandeis, of Boston, the lawyer who was prominent in the Ballinger inquiry has been asked to take charge of the so-called "prosecution," that is to say, the presentation of the case against the present policy of the Administration in releasing lands for private exploitation, both in the coal region and on the coast adjacent thereto. Mr. Brandeis predicts that the inquiry will be extremely fruitful of results. The understanding is that an effort will be made to turn the direction of the investigation more away from the sensational side of the case and toward the broad general question of land legislation already described.

At first, there is likely to be a resumption of the inquiry into the correspondence said to have been found in the files of the Interior Department with reference to the release of lands at Controller Bay, Alaska, suitable for the establishment of wharves and shipping facilities to expedite the taking on of coal when mined in the interior. Most of the more sober-minded men connected with the inquiry, however, have reached the conclusion that the Controller Bay episode is not likely to produce much that will be serviceable in the way of political capital. The bulk of the inquiry is therefore likely to be made up, as already noted, of continued investigation into coal-land values, criticism of the Administration's past and present policy of ownership, and inquiry preparatory to the drafting of new legislation looking to the introduction of some form of a leasing or royalty system.

The Antecedents of an Explosion

The nature of the combustion of gases is receiving new light from the able researches of Dr. Harold B. Dixon.

It was the aforetime conception that when an explosive mixture of gases reached a certain temperature, termed the point of ignition, it flamed, the flame spreading and finally igniting the mixture, and that, if so proportioned, complete combustion took place. This is still believed to be true, but we now have to recognize an earlier stage of chemical action, which Doctor Dixon terms a "pre-flame period of combustion"—a period when the heat may be so great that a certain degree of combustion takes place, but still not so intense that there is any visible burning, no light rays nor any marked increase of heat, no violence of action, nor apparently any propagation.

This silent, dark combustion, without inflammation, will doubtless have to be reckoned with in later discussions of explosions; though its practical bearing is not as yet quite apparent.

It is not impossible that we may find that all explosive bodies, gaseous and solid, which do not detonate, not only burn, but change their chemical structure during the pre-flame period, and demand a certain time limit in which to readjust themselves for combustion, and so to speak "clear decks for action."

An excessive amount of sensible heat is taken up by compound bodies, such as steam at high temperatures, out of all proportion to the rise of temperature as figured from the absorption of heat lower down in the scale. We are feeling our way toward the belief that they are not merely being heated and expanded, but loosened atom from atom at temperatures far below those we formerly declared were their temperatures of dissociation. It may be, also, that a rearrangement of atoms takes place, making isomeric combinations and bodies less stable than those existing at lower temperatures.

Doctor Dixon experimented on the compression of a mixture of carbon monoxide and oxygen in a cylinder, gaging the temperature from the known reduction in volume. He regulated that reduction carefully and thus the temperature resulting therefrom, so that his mixture came repeatedly very near, but below, the ignition point, and found that he could, by a dozen compressions, produce a silent, flameless burning of the carbon monoxide and oxygen into carbon dioxide to the extent of one per cent. in the mixture.

One can imagine many developments derived from considerations of delayed or of partial combustion; a new theory of safety-lamp protection, a cause for the occasionally evidenced remoteness of the focus of explosion from the focus of primary causation, etc. Some of these speculations may be far remote from the truth, however, some may bear investigation.

But why and how and how soon, how rapidly and how far and at what minimum temperature a gas burns, must some day have a practical bearing on the question which will not down, "How shall we avoid these recurrent mine explosions?"

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

Holes should not be drilled into a break in the strata, as the force of the shot is apt to be weakened or the flames may issue through the break and produce the same results as a blow-out shot, that is, ignite the gas or coal dust.

The practice of robbing pillars without regard to the overlying strata, is expensive, dangerous and productive of squeezes and a small recovery as well as demanding a large amount of timbering. It also results in a high percentage of fine coal.

When planning a drift or a slope opening, remember that while the cost of brick or stone arching is considerably higher than timber, the cost of maintenance is much lower. The life of such work is practically unlimited, and it is less liable to damage from runaway trips on slopes.

Forty-five per cent. of all mine timber used in the Anthracite field is destroyed by decay. Wear, insects and breakage account for the rest. Experience has shown that peeling off the bark and the application of certain salts and oils will greatly prolong the life of mine timbers.

The practice of allowing miners to signal themselves away from the shaft bottom, and shaft landings, is dangerous, because they must signal for the cage to be taken away before they get in. In many instances the engineer has to calculate what time should be allowed for the miners to get on the cage. This practice is a fruitful source of hoisting accidents.

When designing a mining plant, it is becoming the custom to have made a large topographical map of the proposed site; on this map locate all buildings that are to be erected, even though it is not proposed to build the entire allotment in the near future. Such foresight often saves cost in erection of foundations, as well as time and labor in future operations. It also tends to a more advantageous and orderly arrangement of the whole plant.

The steam shovel used in the coal stripping of Missionfield, Ill., is the largest in the world. It weighs about 150 tons with a turntable 24 ft. in diameter. The subframe, made of 24-in. I-beams, is 24 ft. square. At each corner of the subframe there is a four-wheel truck, and, in addition, two of the corners rest on cylinders filled with alcohol and glycerin, which are used as hydraulic jacks to keep the subframe level. The machine is 65 ft. long. The dipper has a capacity of 3½ cubic yards.

Discussing the question of turbine pumps in collieries, W. Bolton Shaw says that installing a larger pump in a big pumping station, with a view to shortening the period of pumping, will mean an increase in the maximum load on the power station and additional power will have to be supplied at the generators in order to deal with the increased load, which fact should be considered when making comparisons between different types of pumps, as it will probably add to the cost of installation.

A comparison of the wages of American miners and those of the Welsh miner gives food for thought in many directions. In the Swansea Valley district in Wales, the anthracite miner earns $2.18 per day and the wages of the other employees are as follows, plus 45 per cent. per eight hours: Surface laborer, 74c.; surface foreman, 81c. Underground workers; Laborer, 80c.; hauler, $1; repairer, $1.10; shot men, $1.20; locomotive driver, 99c. Foreman or firemen responsible for the safety of mines, $12.75 per week.

When constructing an overcast, build two side-walls of brick or masonry at the place where the return will cross the intake. Build these in the intake. Enough roof may be taken down to give the necessary hight. Place balks across from one side to the other, or if preferred, strong iron girders may be used in place of timber. Cover these with tongued and grooved boards and coat thick with cement or mortar to make all joints airtight. A brick arching may be substituted for the balks or girders.

The coal deposits of the Crows Nest Pass coalfield of Canada have a total thickness of over 200 ft., distributed in beds varying from a few inches to 30 ft. Of this total thickness, it is estimated that over 100 ft. is workable. The available coal of the field is estimated at over 45,000,000,000 tons. This is without doubt the most extensive deposit of good fuel in western North America. The coal is generally bituminous, but in one locality a fairly good quality of anthracite has been mined as well as semianthracite. The bituminous coal cokes readily.

The effect of the seasons on mine air can be strikingly shown by assuming that the outside temperature of the air in the winter is 0 deg. F. and the relative humidity is 70 per cent. Reckonings made from the dew-point tables will show that under these conditions, every 100,000 cu.ft. of air per minute carries a little over half a gallon of water into the mine, or about 750 gal. a day. With an outside temperature of 80 deg. F. and a humidity of 70 per cent., conditions which may be assumed to exist in summer, 100,000 cu.ft. of air per minute will carry 13.1 gal. of water or nearly 19,000 gal. every twenty-four hours, that is, twenty-five times as much as in the winter.

Mine foremen should measure the air current at the intake and return and near the face of the entries, at least once a week and a careful record should be kept of these measurements. Foremen should be familiar with the use of the anemometer, the water-gage, the barometer, the thermometer and the hygrometer. The anemometer shows the velocity of the air current; the water-gage the resistance offered the current, or its pressure; the barometer the atmospheric pressure; and the thermometer the temperature, while the hygrometer gives the amount of moisture contained in the air. The information obtained from these weekly measurements should be carefully studied by the mine management because the safety of the mine and miners depends to a large extent upon it.

Wetting the mine to lay the dust must be thoroughly done or it is time and labor wasted. As it is most difficult to wet dry coal dust, the pouring of water from a bucket or wetting from the valve of a water-car is of slight value. Roads should be thoroughly watered every day. A force pump should be attached to each water-car for use in wetting roof, timbers and ribs. Where the hoze and nozzle method is used, the piping should extend along all haulage roads right up to the working faces and should be well supplied with taps. The dust should never be allowed to become dry before resprinkling. This method of watering is especially adapted to watering before shot firing. It is also adaptable to roof, rib, tank, and gob sprinkling, in places where the nature of the roof will permit the use of water. Where water has a tendency to create spontaneous gob fires, shale dust should be used.

INQUIRIES of GENERAL INTEREST

Room Widening

In ordinary room-and-pillar workings, which way should the rooms be widened and why?

L. F. E.

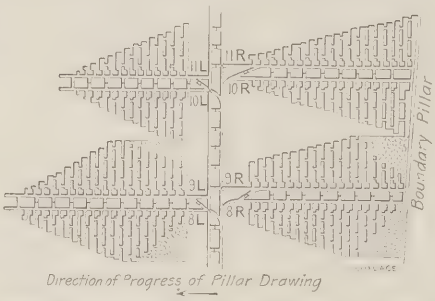
All rooms should be widened in the direction of progress of the pillar drawing. In advancing pillar drawing, the rooms should be widened "inbye" and in retreating, "outbye."

The accompanying heading shows a face heading with eight butt headings, four right and four left. The rooms in the headings to the left are to be driven up consecutively, beginning at the one nearest to the face heading and proceeding toward the end of the heading from which the rooms are turned. The drawing of the pillar between the first and second rooms is to be commenced first and the others are to follow in due order, as is exemplified in the first seven rooms of the eighth and ninth left. This is the most customary method of extracting coal by the room-and-pillar system. In the left-hand headings, therefore, the progress of the pillar drawing will be to the left, therefore the rooms should widen to the left, as seen in the plan (though, of course, when facing the necks of the rooms in their respective headings, those out of the ninth and eleventh left will be widened to the left and those out of eighth and tenth will be widened to the right).

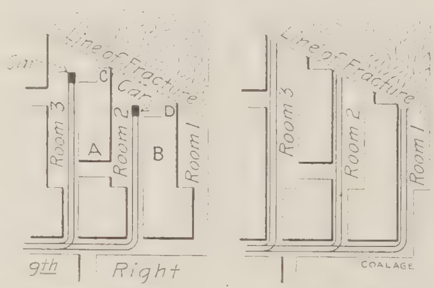
The headings to the right approach a boundary line. Here the first room is located near the boundary line and rooms are started consecutively, beginning at the one near the boundary and proceeding toward the face heading. The pillars are or will be drawn similarly. First the pillar between the first two rooms will be started and then the other pillars consecutively back toward the face heading. This can be seen in the lower right-hand corner where the eighth and ninth right are represented. This method is known as the retreating room-and-pillar system. The rooms should be widened to the left, interpreting right and left as they appear on the plan, not as we regard them facing the room necks from the various headings. Though we are considering the opposite side of the face heading to that which we considered before, the direction of progress of the pillar drawing is still to the left, instead of to the right, as it would have been, had the more customary advance room-and-pillar system been adopted.

The reason for the foregoing rules regarding widening is illustrated below. The figure shows the correct way of drawing the pillar, side by side with an attempt to mine it the wrong way. The figures assume that the miner does not crosscut the pillar in mining back, except in starting his work, but works on the exposed end of his pillar till he reaches the neighboring room.

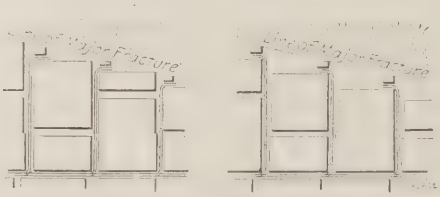
The left-hand drawing shows an enlarged view of rooms 3, 2 and 1, in the



ROOM WIDENING IN ADVANCING AND RETREATING WORK



RIGHT WAY WRONG WAY
SMALL PILLAR METHOD



RIGHT WAY WRONG WAY
CONNELLSVILLE METHOD

ninth right. Between these rooms are two pillars marked *A* and *B*, from which the miner is removing the last cut of the "slab," which he is to take off the end of the pillar. When the roof breaks it probably fractures at the extreme right edges of the slabs *C* and *D*, as shown. The line joining them represents, therefore, the probable line of fracture and it is seen how well the miner can work and yet be free of the fall. The danger point is only reached when he proceeds to take the last cut off the pillar. Very often he has to leave this in place, or, at least, that part nearest the fall.

On the other hand, in the right-hand illustration, is shown the condition that would exist, if the widening of the room was reversed. The miner would be in danger all the time he was working, because the line of fracture would follow him up closely. The remnant of the slab would not help materially to modify the line of fracture and might bar his escape to the neighboring room. To emerge from his cut or to shovel the coal into his car, he must come further into danger than he was in his working place.

Where the Pillars Are Large

In the Connellsville system, where the pillars are large, the advantages of the proper method of widening are quite apparent in the extraction of the last 8x15-ft. section. The pillar is split by an 8-ft. crosscut, leaving a slab of isolated coal 8x72 ft. toward the fall. This is mined in four sections. The last section can be gotten with much less difficulty when the whole weight falls not alone on it and other pillars like it, but also on the edges of the solid ribs between the rooms. The figures below represent this system of pillar drawing with the last section still standing. On the left side the widening feature has been correctly followed and on the right the rule has been disregarded.

Reducing the foregoing statements to their simplest terms, the miner is safest when he is robbing the shorter pillar of his room and the rooms should rarely be so widened that he has to mine the longer pillar where the hazards to his life are greater.

Sometimes where dips are steep and water is present, it is almost impossible to widen those rooms down the hill, which are situated on one side of the face heading; consequently the widening has to be all in one direction, jeopardizing the life of the miner or reducing the completeness of coal extraction, unless the work on the dip side of the face heading is conducted on the retreating system, which latter system, in that case, should be adopted.

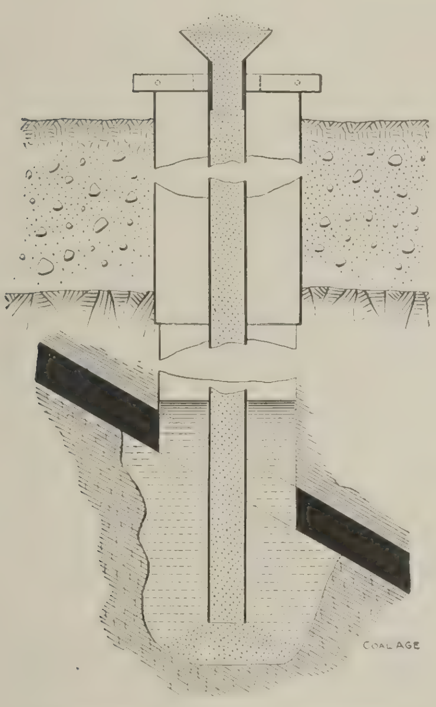
Cementing a Bore Hole

We are putting down a 12-in. hole for steam from the surface to the Dunmore vein, which lies at a depth of about 400 ft. The hole shows 80 ft. of wash and a seam of coal about 5 ft. thick, 135 ft.

from the surface. The drilling has continued to a depth of 156 ft., at which elevation it begins to cave. The strata seem to be loose all around the boring, due to a small local fault. We have, therefore, decided to cement the hole from the present bottom up to the coal, which is 21 ft. above it. The elevation of water in the hole is about 20 ft. above the coal bed. The casing pipe ends at a point 85 ft. below the surface. We will be glad if you or some of the readers of your paper can suggest a practical method by which the hole may be cemented and give the probable time required for the cement to get hard enough so that the drilling may be continued through the cement.

ANTHRACITE ENGINEER.

The accompanying sketch illustrates the question. If the hole were dry, cement grout could be poured in until it was filled up to the required elevation,



SUGGESTED METHOD OF DEPOSITING CEMENT

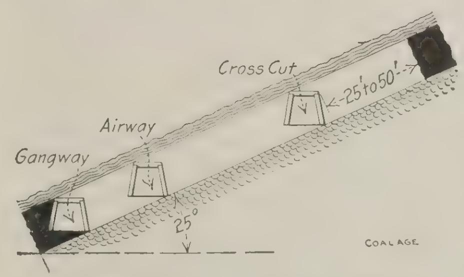
and then it could be allowed to set. But since the hole is wet, it requires a different treatment. Put down another pipe line, 2 or 3 in. in diameter, extend it until the lower end is a few feet from the bottom of the hole. Then clamp it on the surface to the casing pipe as shown on the sketch. Attach a funnel or hopper at the end of the tube. Pour the cement grout in through this hopper. The inside pipe should be raised occasionally so as to prevent choking at the discharge end. The reason for employing an inside pipe is that it is impossible for the cement grout to pass through 41 ft. of water and set properly. If the cement particles had to drop through such a depth, the large grains would settle first, leaving the finer ones suspended in water for such a length of time that they would hydrate and lose strength before settling and the resulting sediment would resemble a mass of sand without strength. By this method, the grout has a chance to expel the water up to the outside of the bore hole and thus the grout can travel in a solid mass without the water passing up through it.

It would be possible to lower the grout in a pipe sealed at its lower end and arranged with a trap valve which would unload when the bottom of the hole was reached, but the simpler plan suggested has been found satisfactory in actual practice.

The time allowed for setting and hardening the cement before the hole can be redrilled is about two weeks, although in some instances a good portland cement has a tensile strength of 100 to 120 lb. per sq.in. under similar conditions.

Irrespirable Mine Air

We have rooms working on a 25-deg. pitch; most of them are about 100 to 150 ft. to the faces from the gangway and have one to two crosscuts on each side, as illustrated in the accompanying sketch. The ventilation at the working faces is not good, for when the face is from 25 to 50 ft. from the last crosscut,



IMPURE AIR IN PITCHING BREAST

the lamp will not burn. There is no firedamp. Our superintendent sent a sample of the air to a chemist for analysis. According to the chemist the following was the composition of the air: Oxygen, 12 per cent.; nitrogen, 88 per cent.; CO_2 and CH_4, traces.

Will you or some of the readers of your paper please explain what the trouble is?

FIREBOSS.

Your case is not exceptional. Including argon under nitrogen, as your chemist has, Dr. Angus gives the following composition for atmospheric air: Oxygen, 23 per cent.; nitrogen, 77 per cent., by weight. Therefore, in the faces of your rooms, oxygen has disappeared to the extent of 11 per cent. and nitrogen has increased by an equal amount. You have a deoxidized atmosphere, probably arising from one of three causes:

1. The shutting in or occlusion of oxygen by water.

2. The combination of oxygen with the coal or lignite or whatever it may be you are working.

3. The formation of carbon dioxide from the oxygen of the mine air by the presence of men, animals, lamps and rotting timber, and its subsequent absorption in water.

It has been found that where water falls in such a way as to hold large bodies of air within it, that the oxygen and nitrogen are absorbed. From a table of constants given by the Smithsonian Institution, we learn that at 20 deg. C., or 68 deg. F., water absorbs 0.901 times its volume of carbon dioxide, 0.01599 times its volume of nitrogen and 0.03137 times its volume of oxygen. It will be seen that water occludes roughly twice as much oxygen as it does nitrogen. As a result, air expelled from water by boiling is always richer in the former than it is in the latter. (See Encyclopedia Britannica, 11th Edition, Volume II, p. 860.) Where water is used for purposes of compressing air by its direct action, as in a trompe, there is always deoxidation of the air.

Deoxidation by Metals and Coal

In metalliferous mines, its deoxidation is frequent, as some metallic bodies readily become oxidized. Coal, we know, will emit carbon dioxide, possibly partly by a slow combustion, though also without the presence of air, by the degradation of its organic compounds. It is known that oxidation of coal takes place during weathering, and also that iron pyrites oxidizes in the presence of air. It appears unlikely that your lack of oxygen is due to solution of carbon dioxide where there is evidence of so little being present.

You ask for a cure. If occlusion is the cause, it would be well to avoid the trompe action; if the trouble is due to the oxidation of the walls of the mine, I would suggest you increase the amount of air and by a brattice carry it up to the face. It is clear that you should not run your ventilation by a continuous current, but split your air and carry it a short way to the workings. It would be well, if it does not have a bad effect on the coal, to run the fan night and day. It is apparent that the stagnation of the air at the face causes excessive oxidation at that point.

It is evident that it is not carbon dioxide you are troubled with, because it would be found at the lower parts of your steep rooms and not at the face. This checks the statement of your chemist. Oxygen and nitrogen, having atomic weights of 16 and 14, respectively, would not separate any more in the mine than they do in the atmosphere.

Yours is an interesting experience, and we will welcome the ideas of others in the matter.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Why Baths Should Be Compulsory

Readers of COAL AGE may be interested in a recent address by Henry Davies, director of mining instruction in the county of Glamorgan, Wales, explaining why, in his view, shaft-head baths should be made compulsory. He says the million coal-mine workers of Great Britain may be fairly assumed to be divided between a quarter of a million homes, and thus the health of at least two million persons may be directly improved if pit-head baths are adopted. Into these 250,000 homes are unnecessarily brought every day dirty, grimy, dust-covered clothes, frequently saturated by rain and by the perspiration of the men or boys who carry them. The wearers are themselves covered by finely divided and closely adhering particles of coal dust as a result of their work in the mines. The wet clothing is placed round the kitchen fire to dry on the fender, the oven door or on backs of chairs—to the discomfort of the housewife engaged in preparing the family dinner and the children struggling over their school lessons. The erstwhile wearers in their turn will perform their ablutions and take their meals in the kitchen beside the baby's cot. In some districts, many of the miners live in one- and two-roomed cottages in which there are no baths. In cases where there are lodgers, the difficulties resulting from domestic ablutions may be readily realized.

Into the British miners' homes, 1775 dead and 159,042 wounded veterans from the industrial battlefield were taken last year. The injuries of the wounded incapacitated them from their daily occupations for over seven days. The number of the sick and of those whose wounds kept them at home for less than seven days, Mr. Davies cannot tell—probably it will bring the total up to 200,000—but his point here seems to be that the home conditions retard recovery.

Some of the Benefits

The man at the coal face will be more alert mentally and physically, more active and energetic, as a result of the invigorating shower bath, and consequently less liable to accident. In the county of Durham, infantile mortality and enteric fever are prevalent, and the chief reason given by medical officers of health is the extremely filthy domestic arrangements. Overcrowding in many colliery districts is reported and there are frequent instances of two families living in houses containing three bedrooms, with as many as 13, 15 or 18 persons in one house. Compulsory shaft-head bathing will begin the needed work of making home cleanliness possible, and the miner will become a better man, morally and physically, while the purifying of his home life will mean the uplifting and sweetening of the lives of his wife and children.

Owing to the misconception and ignorance prevailing as to the character of shaft-head baths, Mr. Davies explains that:

(1) They are not large ponds into which scores of men plunge in succession, spreading diseases from one to another, but spray or shower baths, whereby every bather may receive a plentiful supply of clean water at a temperature which suits him.

(2) There is no danger that the health and vigor of anyone using these baths will be impaired. On the contrary, it will be improved. A Belgian mine manager has found that since the introduction of the invigorating shower bath he has been able to advance the wages of his men by 12 per cent.

(3) The men are not publicly exposed when bathing, but are sheltered in cubicles provided with doors or waterproof curtains. This complaint as to exposure came from a friend who used the family kitchen tub for his daily ablutions.

(4) There need not be any waiting or standing about in wet clothes for a turn in the bath. The men may take 10 minutes each, yet with a provision of 80 to 200 cubicles they may clear out as rapidly as their fellow workmen are being raised through the shaft.

(5) There will be no necessity of going on from a hot room to cold air. The change room may be utilized as a cooling room. In one or two mines in Illinois, the workmen experience no trouble in this direction, even when the temperature outside is below zero. They walk home in their warm dry clothes instead of their cold, wet pit clothing, enjoying their smokes from pipes kept safely in the pockets of their clean clothes.

(6) The clothing will not be left in the change room to rot and spread disease or be stolen. In the absence of the owners it will be hung near the roof or placed in casements to dry; different sets will be sufficiently far apart to prevent the spread of diseases; it will be under the watchful eye of attendants who may possibly execute repairs. At regular periods as decided upon, it must be taken home and cleaned. Blood poisoning, which is now on the rapid increase, owing to dirt from wearing apparel entering wounds, may thus be avoided.

(7) The miners on the continent have not complained of the adoption of these baths. They were taken up voluntarily in Belgium; about 77 per cent. of the workmen now use them where provided, and there is a provision in the new Belgian Coal Mines Bill for making them compulsory. They have been compulsory in Westphalian mines since March, 1900, and no wish to discontinue them has come from the workmen or workwomen.

(8) The compulsory provision of suitable cottage baths, even if possible during the next 20 years, will not remove the objectionable features, that the miners will sometimes enter upon their work underground in wet clothes, and will always bring dirty mine clothing into the home at the end of the day's shift.

R. L. LAWRENCE.

Manchester, England.

Sanitation of Coal Mines

American coal operators are giving closer attention to the sanitation of their mines, and it is probable that the following summary of a report made by a committee appointed to investigate such conditions, in the mines of England, will be of interest:

An outbreak of glanders at a coal mine, it is conceivable, might become a very serious matter, not merely as regards the horses, but also the workmen employed below ground. Careful and thorough inspection of the animals and the maintenance of sanitary conditions are highly essential where it is desired to maintain a clean bill of health. The mysterious death of a horse in one of the pits in South Wales engendered a very strong suspicion that glanders was present. Occasion was taken to make representation in the matter in the House of Commons the ultimate result being that instructions from the Home Office were received by Joseph S. Martin, I. S. O. and D. Rocyn Jones, M. B., D. P. H. to make a thorough investigation.

Among other things, these commissioners were informed that horses occasionally relieved themselves in main roadways and return airways, and they are disposed to the view that such practice might be serious and lead to:

(*a*) Possible danger of an air borne outbreak of typhoid fever, or even ankylostomiasis spreading if a diseased miner should happen to be employed in the collieries. Dry and dusty mines would particularly favor the spread of typhoid, while warm and moist mines would tend to foster ankylostomiasis if once introduced.

(*b*) Possible danger of blood poisoning following upon the access of polluted dust to wounds and abrasions, slight injuries so common to the miner.

From the report prepared by Messrs. Martin and Jones some suggestions may be extracted for the benefit of the coal-mine communities in the United States. The seriousness of the matter cannot be gainsaid, and it is a wise axiom that "an ounce prevention is better than a pound of cure." The recommendations are:

There should be sanitary rules incorporated in the law in regard to both the surface and underground.

Persons employed underground in mines should be required, so far as reasonably practicable, to make a practice of relieving themselves on the surface before descending into the mine or going underground, so that their having to do so underground should be exceptional and an unavoidable necessity.

PROVIDING SANITARY CONVENIENCES

Sanitary conveniences, in the form of galvanized pails, should be provided in suitably arched or otherwise convenient places throughout the mine, for persons employed in the roadways or other parts of the mine[1].

The soiling of roads by excrement (whether hauling, air or other roads) along which persons travel, from time to time, should be prohibited and any contravention should be subject to penalties.

The sanitary conveniences provided, and their surroundings, should be constantly maintained in a clean, serviceable and sanitary condition; any person soiling them or their surroundings should be held liable to penalty.

The excrement from the closets should be scavenged to the surface frequently and be disposed of either by means of incineration or burial.

Underground stables should be required to be constructed and fitted in a manner to allow of proper sanitary conditions and they should be constantly maintained in a clean and well ventilated state, being thoroughly lime-washed at least every three or four months. Stable manure and refuse should be sent out of the mine daily.

Stables and horses, both underground and upon the surface, should be examined and reported upon at least once a month by a qualified veterinary surgeon, who should note in detail the condition of the stables and of each horse as regards its condition, health, sores and injuries, such report to be kept in the manager's office.

Before horses are employed in or about a mine they should be tested by the Mallein test and certified by a qualified veterinary surgeon to be free from glanders and fit to be employed at the mine.

The law should provide for ample and suitable sanitary conveniences or accommodation on the surface, which if the conditions allow, should be flush tank closets properly connected with the sewers of the district. The maintenance of these conveniences in a clean and suitable condition for use should be provided for as well as penalties for soiling them.

Latrines should not be allowed either above or below ground which are constructed to discharge direct into running streams.

O. R. HAWORTH.

Bolton, England.

[1]For description of an underground closet that has been successfully used in some of the American metal mines the reader is referred to "A Sanitary Underground Latrine," in the *Engineering and Mining Journal*, Vol. XCI, page 556.

A Working Model of a Colliery

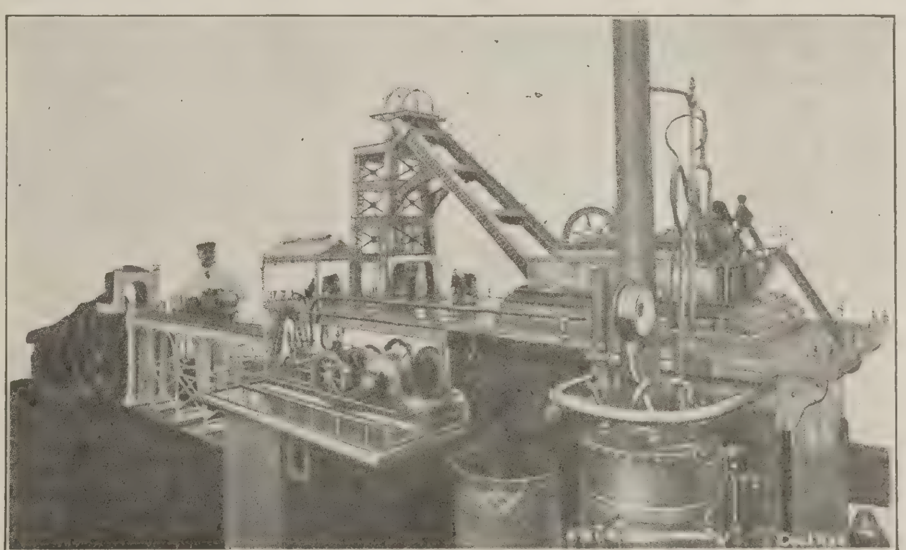
COAL AGE readers may be interested in the accompanying illustration showing what must be called a monument of industrious application. It represents a working model of a colliery constructed in his spare time by T. Thomas, of Bargoed, Glamorganshire, engineer in a Welsh colliery. As it stands it represents 25 years of application to model building and is entirely the work of the gentleman named.

The central feature of the collection is the headgear, which is an exact model of a well-known headgear in Wales,—that at the Treharris colliery. This is 3 ft. 6 in. long by 3 ft. 6 in. high, by 15 in. wide, and is made of brass throughout. In the building of this section of the model, 10,325 copper snapped rivets have been put into place, and its total weight is 161 lb. The hoisting rope has attached to it a model of Walker's detaching hook, for the prevention of overwinding, and hoisting is effected by means of a reversing double engine, weighing 200 lb. and having cylinders $1\frac{1}{2}$ in. diameter by 3 in. stroke. There is also a depth indicator worked off the drag link. Steam is applied both to this and to a fan engine by the boiler shown in the figure, the dimensions of the fan being 4 ft. by 2 ft. by 2 ft. high.

As is evident from the illustration, there are model pit cages, ten-ton trucks, screens, tipplers, trams, etc., and the coal when loaded into trucks is transported from the colliery over a viaduct, to the entrance of a tunnel by means of a steam locomotive.

MODEL DEMONSTRATES WORKING OF DETACHING HOOK

To make the model complete, the hoisting engine is driven by a model engine driver, fashioned in steel, who is 7 in. high, and who, on receiving a signal from a similar model brakesman, starts his engine. The model is capable among other things of demonstrating the working of the detachable hook in case of an overwind, and at the recent mining exhibition at Manchester, England, it attracted considerable attention, not merely as a curiosity, but for its undoubted technical interest. It is rarely the case that a model is so completely finished throughout in metal (brass and steel) and it will therefore be interesting to mining engineers in America, to know that it will probably be exhibited at the great exhibition which is to be held at San Francisco to celebrate the opening of the Panama Canal.



MODEL OF A COLLIERY CONSTRUCTED BY A BRITISH ENGINEER

Liquor Problem in Mining Communities

SPECIAL CORRESPONDENCE

"Business is business" sounds well when stated by the average man, but it sounds farthest when stated by the man who can forge words into deeds.

For many years thousands of farmers said: "A great need in the rural districts is better roads." But they continued to lose time in hauling produce to market and to "wear out" horses, wagons and patience traveling over roads filled with rocks, cut up with "ruts" and running over heavy grades.

The automobile brought in a new factor—the man of wealth and political power. What was the result? In a short time "State made" macadamized roads began to take the place of old-time highways. Yes, it makes a difference who says "Business is business."

For generations many people in the ordinary walks of life have organized and complained and waged warfare against the liquor traffic and much good was accomplished, but when the men back of the great industries of the country fully realize that the drink traffic interferes with the wheels of industry, that it is an economic problem and these men speak, something will happen that will sound like the driving of nails into a liquor-traffic coffin.

The heads of some of the biggest industries in the country are sorely perplexed over the loss their enterprises sustain through the liquor traffic and they are beginning to say "Business is business." These men are not engaged in temperance-reform work nor are automobilists running truck farms; but their ability and their large interests make possible for them what is impossible to less able and less influential interests.

The great question is, as ever, "How can we successfully deal with the problem?"

Men are asking the question today who are in the habit of answering their own questions, and that is significant.

THE CONTROLLED SALOON A FAILURE

The controlled saloon has proved a failure, at least under existing laws. The "control" fails to make good or else the court's interpretation of the law prevents its operation under rigid control and restrictions.

[NOTE—This is the second article discussing the above subject.]

We quote an official of a large coal company: "Regarding our experience here, this community was better off when we had a tap room. You will understand, of course, that our tap room was run absolutely without profit to this company, as under an arrangement made with the county court all the profits derived from the operation of the tap room were devoted to public welfare. I might say in this connection that this was done primarily for the reason that the interests controlling the company would not participate in the handling of liquor in any manner which would give them profit, and the idea of handling this business through a tap room was that the traffic might be absolutely controlled and restricted.

"Unfortunately, however, it appeared to our county court, after having granted us a license on these terms for one year, that such an arrangement was outside the letter of the law, and it refused to renew our license for the present year. You will also understand that in our tap room we sold nothing but malt liquors and soft drinks, and in connection with the tap room we ran a restaurant. In the conduct of our tap room we could be as arbitrary as we chose, not working at any time for profits, with the result that the rules we enforced did undoubtedly tend to restrict the use of liquor in our town and, at the same time, they were not made so strict as to cause any serious complaint from our men.

INSOBRIETY ENSUES

"Since our tap room was closed, we have experienced the same trouble that exists in every mining town in this district, at least so far as my experience goes. There is no question but that the consumption of liquor has greatly increased; our town is not nearly as orderly as it used to be, and during the first month of no license, three murders were attempted, one of which, I believe, resulted fatally, and another resulted in disabling the victim for life. The trouble is that now the men club together and get a great quantity of liquor, which it appears to them must be consumed with the least possible delay, and I have never yet known of any great amount of delay in getting away with a supply of this kind around the miners' houses or boarding houses.

OUTPUT WAS CONSTANT

"During the last year while we were operating the tap room, one who did not know our pay days would be absolutely unable to pick them out by looking over our daily-tonnage reports; in other words we figured that we did not lose a single ton of output through our men being drunk; on the contrary, strange as it may seem, our pay days used to show not only a good tonnage, but, if I am not mistaken, our record tonnage was absolutely broken on one particular pay day. Things are decidedly different now; last week I should say, we lost fully 15 per cent. of our normal output on account of a couple of weddings and christenings.

"Generally speaking, I am as much opposed as anybody to operating the saloon, and personally I am extremely proud of the high attitude our company took in this matter; namely, that of refusing to participate directly or indirectly in any profit derived from conducting a saloon business; and I regard it as extremely unfortunate that our attitude in this matter not only lost us our license and took away from us the control of this traffic, in a large measure, but also that our motives were misunderstood by some of the temperance people in this county, and I can't help thinking that their mistaken assaults on us contributed largely to our present troubles.

THE SUCCESSOR OF THE CONTROLLED TAP ROOM

"As conditions are now, speaking for our own town, the amount of liquor that is shipped in by freight and express and hauled in by wagons is simply appalling, and I seriously question, if the figures could be accurately collected, if we could make anyone acquainted with this business believe to what extent it has grown. After having gone into this matter with the greatest care, and appreciating that with a certain portion of our foreign workmen the question of drinking beer is much the same with them as that of drinking milk with you or me, I have come to the conclusion that the only effective remedy is to put the control of the traffic in the hands of responsible parties who will handle it with common sense and who will refuse any money profit therefrom. And I am coming to believe that this can best be done, not by running tap rooms, but by being intrusted with the entire control of every bit of liquor that comes within our jurisdiction.

"I should also add that when we were running our tap room, most of the drinking was confined to beer while now, as

the liquor is shipped in by express, considerably more whisky is consumed, and I have no doubt it is of the rottenest kind. I do not need to point out to you how much worse this makes its effects."

In the above instance, the law was enforced to close the "controlled tap room." There are hundreds of cases where the law fails to be enforced to prevent methods which have no element of restriction, but which solely tend to demoralize.

Anthracite First Aid Meets

The team of the Brisbin colliery, belonging to the Lackawanna Coal Company, on Sept. 16, defeated its fifteen opponent teams in the first-aid contest held at Valley View park, near Pittston, under the auspices of the American Red Cross Society, the contest being in charge of Dr. M. J. Shields, who is the field agent for that institution. By its victory the team not only gains temporary possession of the Muckle cup, but also is entitled to represent the various coal companies at the National first-aid contest to be held in Pittsburg.

Several hundred people were at the park to witness the events and the teams represented fully 70,000 mine workers. Other successful teams were as follows:

First Event—First, Brisbin colliery, Lackawanna Coal Company; second, Clarence colliery, Hillside Coal Company; third, Centralia colliery, Lehigh Valley Coal Company.

Second Event—First, Law shaft, Pennsylvania Coal Company; second, Pine Brook colliery, Lackawanna Coal Company; third, Parrish and Buttonwood collieries, Parrish Coal Company.

Third Event—First, Forty Fort colliery, Temple Iron Company; second, South Pittston colliery, Pennsylvania Coal Company; third, Stevens-Seneca colliery, Lehigh Valley Coal Company.

Fourth Event—First, Hazelton colliery, Lehigh Valley Coal Company; second, Dunmore colliery, Pennsylvania Coal Company; third, Price-Pancoast colliery, of the Price Coal Company.

Fifth Event—First, Brisbin colliery, Lackawanna Coal Company; second, Stevens-Seneca colliery, Lehigh Valley Coal Company; third, Mayfield colliery, Hillside Coal Company.

The events were as follows:

No. 1—One man. Time allotted, 10 min. Fracture of bones of nose with severe bleeding, caused by the kick of a mule. Stop bleeding and dress with first-aid packet.

No. 2.—Two-man contest. Time allotted, 10 min. Explosion of keg of powder causes severe burns of hands, face and chest. Dress the injuries.

No. 3.—Man lying on live wire. Remove and treat.

No. 4—Right collarbone broken. Left foot badly crushed, not bleeding severely. Dress injuries.

No. 5—General team contest. Man unconscious and suffering severely from shock. Right hand smashed and cuts in palm. Wounds bleeding freely. Severe scalp wound and hemorrhage from artery. Simple fracture of third left thigh. Treat and dress.

The judges of the contest were: Capt. A. W. Williams, of Philadelphia; Major Charles Lynch, of Washington, and Major J. H. Allen, Ft. Myer, Virginia.

Shamokin Meet

The Susquehanna Coal Company held its second annual first-aid contest on Sept. 16, at Edgewood park, Shamokin. The teams participating represented the Susquehanna Coal Company's collieries at Nanticoke, Glen Lyon and William Penn, together with allied operations, the Mineral R. R. and Mining Company, of Shamokin and Mt. Carmel; the Summit Branch Mining Company, of Lykens and Williamstown; also the Lytle Coal Company, of Minersville. Special trains took the officials and corps from Wilkes-Barre, Nanticoke and Lykens. Supt. W. R. Reinhardt, with his aids, had completed admirable local arrangements. Upon arrival all parties were given a badge which entitle them to all the privileges upon the grounds. Luncheon was provided for 800 persons, including first-aid corps, officials, colliery bosses, clerks and guests, in the park pavilions. The baseball ground was used for the contest, canvas being placed on the ground. Penants bearing a number and the names of each of the forty-one corps marked the places. The program and tally sheets showed corresponding numbers.

Wilkes-Barre Mining Institute

Wilkes-Barre District, Y. M. C. A. Mining Institute, opened its yearly session by a social entertainment with addresses, Saturday, Oct. 7. The classes met for study on Tuesday, Oct. 10.

In addition to the night classes, which occur Tuesday and Friday evenings, a day class is offered for those men who work at night. This class will meet at 1:30 o'clock Mondays and Thursdays, and will take up the same subjects taken up in the night classes.

Charles Enzian, of the bureau of mines, will be supervising principal, as heretofore. W. D. Thomas, of the Kingston Coal Company, will teach arithmetic, mine law and ventilation to the first-year classes and ventilation to the second-year classes. E. B. Wagner, of the Lehigh Valley Coal Company, will teach arithmetic to first-year classes and mechanics, air compression and electricity to second- and third-year students. Thomas Price, of the D. L. & W. coal department will teach ventilation and gases to the first-year classes. Edward Roberts, of the Lehigh & Wilkes-Barre Coal Company, will teach the day class, which will meet Mondays and Thursdays at 1:30 in the afternoon.

Carbondale Mining Institute

The Carbondale District Mining Institute held its first regular monthly meeting for the 1911-12 season in Watts hall, Carbondale, Penn., Friday evening, Oct. 6, 1911.

Papers were read by James R. Williams and President P. J. Moore. Various members participated in the discussions. Mining Secretary C. L. Fay gave a short address.

The greater part of the evening was taken up with the business of the institute in preparation for the fall and winter work. Particular attention was given to the subject of night schools. Teachers Panchisin and Yurkorsky were present and reported that students at Forest City, Browndale and Mayfield were ready to enroll, and from all reports and indications there will be a satisfactory enrollment at each of these points. A large number of the men who attended the night schools at Forest City and Mayfield will continue this season and take up advanced English and arithmetic.

It is hoped that schools can be opened in Simpson for the fall term some time during the coming week.

First Aid Problems

The following are the problems to be exemplified during the National First-Aid Meet at Forbes Field, Pittsburg, in connection with the National Mine Safety Demonstration:

1. Treat a lacerated wound of the right side of the head (temple), and a lacerated wound on the top of right shoulder. One-man event; four minutes.

2. Treat a punctured wound over the left eye and lacerated wound of palm of right hand. One-man event; four minutes.

3. Treat a simple fracture of left collar bone and simple fracture of jaw. Two-man event; two minutes.

4. Treat a dislocated right shoulder and simple fracture of right knee. Two-man event; two minutes.

5. Treat conditions of a man who has fallen on an electric wire, back down, clothing burning; rescue, extinguish fire, treat back and upper arms. Team event; ten minutes.

6. Treat conditions of a man who has fallen on an electric wire face down; rescue and extinguish fire, treat chest and upper arms. Team event; ten minutes.

7. Treat gas burns of face, neck, ears and hands. Team event; ten minutes.

8. Treat gas burns of hands, right arm and shoulder. Team event; ten minutes.

9. Treat a broken back and simple fracture of right forearm. Team event; twelve minutes.

10 Treat a dislocated hip and simple fracture of collar bone. Team event; ten minutes.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Sines and Cosines and Their Use

Please explain the meaning of the words "sine" and "cosine" and the way in which they are used by surveyors.

By Special Request

The words are used to express or define the relative lengths of the sides of a right-angled triangle, that is, of a triangle having one angle of the three a right angle. The sine and cosine are not fixed quantities but vary in relation to the spread of the angles considered. Nor are they the same for any two angles in a triangle, unless two angles are equal. They are, however, the same for every angle of a certain given spread or degree.

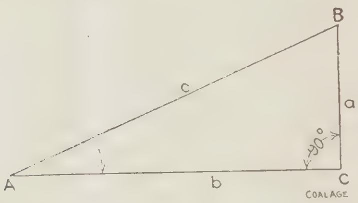

Figure Illustrating Sine and Cosine

In the triangle illustrated, which we name ABC after its three angles A and B and C, the sine of the angle A is defined as

$$\frac{\text{The length of the line between } B \text{ and } C}{\text{The length of the line between } A \text{ and } B}$$

or as it is usually written $\frac{BC}{AB}$. It is customary to say that the side, opposite angle A, has a length of a units—a feet or a yards or a meters. It is customary in a similar way to say that the side opposite C is c feet or c yards or c meters long or that it is c units in length. So we can cut the statement short and say sine A or *sin. A*, as we usually write it, equals $\frac{BC}{AB} = \frac{a}{c}$ because $BC = a$ and $AB = c$. But it must be remembered that the units used must be similar; that if a is in feet, c must be in feet. You will have to memorize that $sin.\ A = \frac{BC}{AB} = \frac{a}{c}$, because sine is merely a name for a ratio and it is necessary to remember what ratio it is, just as you would have to hold in memory the meaning of any other word. It is not a principle but a conventional name. The cosine of the angle A or cosine A, or as we still further cut the wording down to its lowest possible form,

$$Cos.\ A = \frac{\text{The length of the line between } A \text{ and } C}{\text{The length of the line between } A \text{ and } B} = \frac{AC}{AB}.$$

In other words the sine of an angle of a right-angled triangle is the ratio or comparative length of the opposite side of the triangle, to the long side, which forms one of the limbs out of which that angle is composed. This side we term the hypotenuse and, as you see, it is the side opposite the right angle.

The cosine is the ratio of the other, or short limb of the angle to the long limb. The short limb is called the "adjacent" or near side, though you will see it is not any nearer the angle than the long side or hypotenuse, but the reason for its being called "adjacent" is because it is near or adjacent not only to the angle we are discussing, but also to the right angle.

Now, seeing that the line AC is opposite the angle B, we shall say it is b units long, that is b feet, b yards or b meters, as the case may be, according with our use of foot, yard or meter units.

Thus the hypotenuse $= AB = c$; the opposite side $= BC = a$; the adjacent side $= AC = b$.

Suppose, for an example, in surveying we take a slope 1200 ft. long meas-

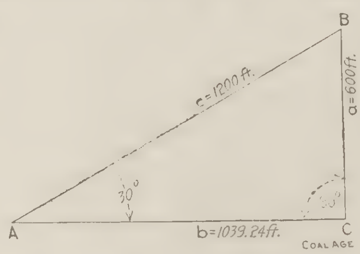

Figure Showing Rise and Length of Slope

ured on the slant, with an angle to the horizontal of 30 deg. We have seen that $sin.\ A = \frac{a}{c}$.

Now multiplying both sides by c, which will leave them still equal,

$$Sin.\ A \text{ becomes } sin.\ A \times c,$$

$$\frac{a}{c} \text{ becomes } \frac{a \times c}{c} = a.$$

Hence

$$a = sin.\ A \times c.$$

But $c = 1200$ and we find in the tables that *sin.* 30 deg. is equal to 0.5.

Therefore a will equal $0.5 \times 1200 = 600$ units. Now these units must be the same units as we used in measuring the slope; that is, they must be foot units or feet.

Therefore $a = 600$ ft., or the slope rises 600 ft. in its full length.

To get the horizontal length we take the cosine definition: $cos.\ A = \frac{b}{c}$; multiplying both sides by c we have $cos.\ A \times c = \frac{b \times c}{c} = b$.

Therefore, getting the cosine from the tables and remembering that $c = 1200$ ft., we have

$b = cos.\ A \times c = 0.86603 \times 1200.$

Therefore $b = 1039.236$ feet.

Therefore the slope extends a horizontal distance of 1039.236 ft. and if we go 1039.236 ft. on a level and then rise 600 ft. straight upward we will arrive at the head of a 1200-ft. slope like that in the problem we are solving.

Computation of Altitude

Original Question

In the illustration, P is the top of a church steeple; C is the projection point obtained by dropping a perpendicular line from P. At A a sight is taken to P and the angle of elevation from the horizontal is measured and is found to equal 20 deg. 15 min. At B, a point 500 ft. from A and on the extension of the line CA, another sight is taken and the angle of elevation to the top of the steeple P is found to be 10 deg. 42 min. Find the hight of the steeple (PC) above the level at which the sights were taken and the distance AC, designated on the plan as x.

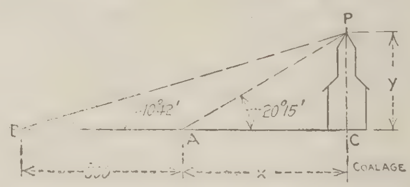

Figure Accompanying Problem on Steeple Hight

$$\frac{y}{x} = tan.\ 20\ deg.\ 15\ min.; \qquad (1)$$

hence multiplying both sides of the equation by x,

$$y = x\ tan.\ 20\ deg.\ 15\ min.$$

and $\frac{y}{x + 500}$ also equals *tan.* 10 deg. 42 min.; hence multiplying both sides of the equation by $x + 500$,

$$y = (x + 500) \times tan.\ 10\ deg.\ 42\ min. \quad (2)$$

The y mentioned in equation (1) is the y of equation (2), and since things which are equal to the same thing are equal to one another,

$$x\ tan.\ 20\ deg.\ 15\ min. = (x + 500)\ tan.\ 10\ deg.\ 42\ min.$$

From tables

$$tan.\ 20\ deg.\ 15\ min. = 0.36892$$
$$tan.\ 10\ deg.\ 42\ min. = 0.18895.$$

Hence

$$0.36892\,x = (x + 500) \times 0.18895,$$
$$0.36892\,x = 0.18895\,x + 500 \times 0.18895,$$
$$x\ (0.36892 - 0.18895) = 94.475.$$
$$0.17997\,x = 94.475$$
$$x = \frac{94.475}{0.17997}$$
$$x = 524.95\ ft.$$

We have seen that $y = x\ tan.$ 20 deg. 15 min. and now we know $x = 524.95$, we can write $y = 524.95 \times 0.36892 = 193.66$ ft. This is the elevation of the steeple above the level of sight.

Sensitiveness of Fan Doors

Ques.—The "explosion door" on the top of a fan shaft is curved to a radius of 16 ft. and measures on a straight line from hinge to lip, 8 ft., and is 8 ft. wide. If the water gage be 4 in. and the door rests at an angle of 45 deg., what must be the weight of the door if it is on the point of opening at that air pressure?

Ans.—The radius of the door does not affect the result. The gross effective steady pressure of still air on the curved surface $A\,B$ is no greater than on the plane chord surface between A and B. For the pressure on the surface of the curved face is at right angles to it, and at only one point of the cross-section is that pressure at right angles also to the chord $A\,B$. On one side of that point, the pressure is inclined to the left, on the other to the right, and the amount of inclination is the same for like points on the right and on the left, so that the amount one pressure unit would try to push the door to the right; another pressure unit would try to push it to the left. The only components of the pressure of the air, not so balanced, and made of no effect in the ultimate result, are those at right angles to the chord $A\,B$.

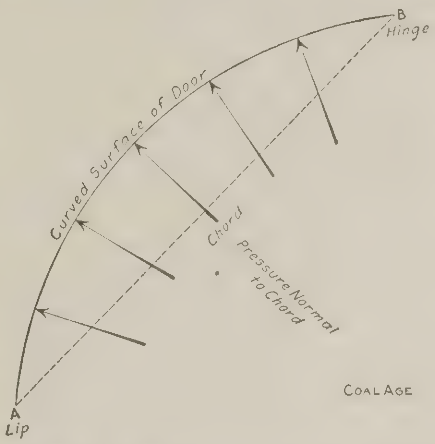
The pressure in pounds per square foot equals the water gage in inches times 5.2 lb.; because a body of water one foot square and an inch deep weighs 5.2 pounds.

So the pressure on the door in a direction at right angles to the chord surface $A\,B$, which is the sole effective pressure on that door, equals the length of the chord $A\,B$ in feet multiplied by the width of door in feet times the water gage in inches multiplied by 5.2 lb. equals 8 ft. times 8 ft. times 4 in. multiplied by 5.2, equals 1331.2 pounds.

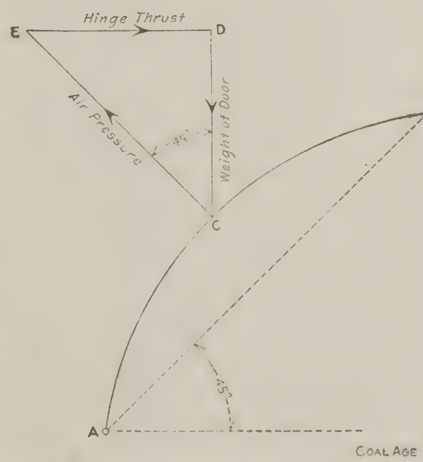
But the weight of the door acts vertically downward, so that only that part of the unbalanced air pressure which acts vertically upward can effectively oppose itself to the weight of the door.

We can now resolve the unbalanced effective pressure on the door into two components or parts, one acting vertically and one horizontally.

In the accompanying sketch let $C\,E$ be proportioned to the whole pressure on the door as calculated. Draw $E\,D$ horizontally from E and $C\,D$ vertically from C to meet $E\,D$ in D. Then $E\,D$ is the reaction of the hinge against the thrust of the door, and $D\,C$ is the weight of the door acting to balance the air pressure.



Normal Pressure on a Curved Door



Forces (Acting) on an Explosion Door

Now, $E\,C$ is at right angles to $A\,B$ and $D\,C$ is at right angles to a horizontal line. Therefore, the angle between $E\,C$ and $D\,C$ must be equal to the angle that $A\,B$ makes with the horizontal, namely, 45 degrees.

The forces in equilibrium are the air pressure $C\,E$, acting to open the door; and the weight of the door $D\,C$, acting to close it. These forces act about the hinge B as a center. According to the principle of moments,

$$CE \times \frac{AB}{2} = DC \times \frac{AB\ cos.\ 45°}{2}$$

or

$$C\,E = D\,C \times cos.\ 45\ deg.$$

and

$$DC = \frac{CE}{cos.\ 45°} = \frac{1331.2}{0.707} = 1882\ lb.$$

There is one consideration which has not been stated. The door should be symmetrically built so that its center of gravity is coincident with the center of pressure, otherwise the moment of the weight at the hinge will be unequal to the moment of the air pressure at the same point, and a correction would have to be made for this inequality of leverage. In fact, if built exactly of equal weight for unit length along the curve, the center of pressure would be a trifle further from the hinge than the center of gravity, owing to the curvature.

Example—Given a symmetrical door with a chord length of 6 ft., and 6 ft. wide, weighing 500 lb.; also having its chord line at an angle of 30 deg. to the horizontal. What would be the water gage of air under such pressure as would just suffice to open it?

Answer—2.3 inches.

West Virginia Questions

Glen Jean Examinations—General Preliminary Questions Continued From Oct. 14

Shafts and Hoisting Engineers

Ques. I—(a) What does the law require in shaft mines as to hoisting machinery with reference to its inspection, means of signaling and communication from top to bottom of shaft, safety catches and brakes, passageways and regulations as to the hoisting of men? (b) What kind of engineers must be placed in charge of hoisting machinery?

Ans.—(a) The law requires that the hoisting machinery must be inspected once in each 24 hours by some competent person.

A metal tube, through which conversation may be held between persons at the top and at the bottom of the shaft, must be provided, also the ordinary means of signaling, safety catches, cover on the cage, safety gates at ground landing and adequate brake on drum. There must also be a traveling-way made around the shaft, not less than 5 ft. high and 3 ft. wide. (Sec. 9.) The engineer must not allow anyone to interfere with any part of the machinery unless he is properly deputed to do so. No person shall interfere with or intimidate the engineer in the discharge of his duties; no more than ten men shall ride on a cage at one time and no person shall ride on a loaded cage or car in any slope or shaft. (Sec. 10.)

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Briefs have been filed with the U. S. Supreme Court in behalf of the railroad companies which are defendants in the so called coal-roads' cases. Probably the argument for the Reading road is the most representative of the set and brings out as clearly as any the point of view of the railroads in this proceeding. The Reading company, with the other defendants, was charged with violating the Sherman anti-trust law, because it had joined with them in the acquisition of the capital stock of the Temple Iron Company, and because of certain transactions of that company.

The new briefs, however, do not go over the ground covered in the other arguments that have been presented on earlier phases of the subject, but direct attention very largely to the control of the capital stock of the Central Railroad Company of New Jersey and its relation to the carrying of coal. The point made by the Government is that the action of the Reading in controlling the Central of New Jersey brought under one controlling power not only those two carriers, but also the Reading and the Lehigh and Wilkes-Barre coal companies, thereby destroying every motive for competition between these railroad companies, and establishing a monopoly of the transportation of anthracite coal and also ending a competition between the coal companies in the sale of coal.

Reading Company's Argument

The Reading asserts that the Central of New Jersey does not operate a line that is substantially parallel to its own and which, in the absence of a restraining agreement, would be a competitor for traffic. It contends that the two roads serve entirely distinct parts of the State. The reason for the acquisition is assigned as being the purpose of enabling the Reading to cope with harbor interests in New York, which made it difficult for that road to get proper terminal facilities there.

Furthermore, it is stated that the Central of New Jersey and the Philadelphia & Reading are, and always have been, since their construction, connecting lines supplementing one another in the formation of through routes for the transportation of coal. Since the acquisition of control it is claimed that there has been no material change in the relations between the two roads, but all of the arrangements existing between them were consummated prior to that time. The anthracite-coal deposits, it is contended, are divided into five or six separate and distinct basins located miles apart and segregated from one another by mountain ranges, so that neither of these roads reaches or serves the anthracite coalfields as a whole, but on the contrary, each penetrates only portions of separate and distinct fields not penetrated by the other and severally reaches some, but not all, of the collieries located in those fields.

No Diminution of Output

As for a diminution of tonnage on either line resulting from the combination, it is claimed that there is no evidence to that effect, but on the contrary the gross tonnage of anthracite over both roads has materially increased since the consolidation. Figures for anthracite tonnage show that on the Reading 13,537,464 tons out of 43,603,585 were carried in 1908 against 10,672,556 tons out of a total of 24,404,294 in 1900. The Central Railroad of New Jersey shows an anthracite tonnage of 9,663,927 out of a total of 26,240,555 tons in 1908 against 6,632,075 tons out of 16,668,997 in 1900.

Each of the producing coal companies, it is pointed out, preserves its individuality in the ownership, control and operation of its own property, under its own board of directors, having a different personnel, and each is separately amenable to the law insofar as its doings come within the regulative power of Congress. But as to the ownership of lands, the operation of mines and the preparation of coal for the market, none of these matters, it is asserted, is commerce at all, much less interstate commerce, and they are all beyond the regulative power of Congress, which is confined to that portion of production from the mines which has been or is to be put into transit in interstate commerce. Control over such commerce is the only way in which Congress can constitutionally regulate operations in coal.

Rebates in New Guise

Action by the Interstate Commerce Commission suspending the tariff on coal recently filed by roads connecting with the Tennessee Coal, Iron and Railroad Company is intended to pave the way for a discussion before the commission of the question whether short lines of railway, owned by industrial concerns, are to be allowed practically to obtain rebates by securing a favorable division of through rates from connecting lines of road. This is also a point upon which the Stanley investigating committee of the House of Representatives has been insisting in the course of its recent inquiry into the doings of the United States Steel Corporation.

Coke-rate Controversy

The coke-rate controversy has been brought to a definite stage of development before the Interstate Commerce Commission. The rates complained of are those from the Connellsville coke region to South Chicago, Indiana Harbor and other places in the same territory. These rates are now set at $2.50 per ton for coke as against $2.35, which prevailed prior to the middle of last June.

Originally the coke from the Connellsville region to the Middle West moved partly on a rate of $2.35 and partly on a rate of $2.65 per ton. About 95 per cent. of the coke, however, moved at the lower figure. When the classification committee of the Western roads sought to bring about a greater degree of uniformity in classification, this rate was changed in each case to $2.50, which amounted to an increase of 15c. per ton on far the larger part of the coke. The Wisconsin Steel Company promptly complained, alleging that it purchased annually some 460,000 tons, so that it was a heavy loser by the change in rates.

At first the Interstate Commerce Commission seemed to be inclined to put the old rate into effect, but finally allowed the increase to occur, so that the only course open to the consumers was a formal complaint to the commission which has now been made and briefs filed as already indicated. The contest will involve considerable discussion of the question of uniform classification and whether or not uniformity is to be attained at the expense of the shipper by raising rates from the lower to the higher level.

The Meeker Case Again

The United States Court of Comerce, after a lengthy hearing in the Lehigh Valley coal case, has overruled the application for an injunction against the Interstate Commerce Commission with reference to the new rates on coal from the Lehigh district to tidewater. This brings a famous case one stage nearer to conclusion. The Lehigh Valley case was formerly the so called Meeker case and brought before the Interstate Com-

merce Commission the whole question of rates from the Lehigh district to tidewater.

After full consideration the Commission directed the railroads involved to pay to the independent coal operators reparation of over $220,000 for excessive charges made during the time the old coal rates were in operation. In addition to this the new schedule of rates for coal moving from the Lehigh district to tidewater, which was to have been put in operation Nov. 15 of this year, was ordered into effect.

Alabama

Birmingham—A $30,000,000 merger of the Alabama Consolidated Coal and Iron Company and the Southern Iron and Steel Company, of Alabama, is said to be nearing completion.

Colorado

Boulder—As the result of the sale of the property of the Northern Coal and Coke Company to the Rocky Mountain Fuel Company, it is authoritatively stated here that the end of the long-continued coal strike is in sight.

The American Fuel Company, which some time ago purchased the Centennial mine at Louisville, has now also become the owner of the Economic and Mitchell properties.

Canon City—At the mining plant of the South Chandler Coal Company, about nine miles south of this city, known as the Cuckoo mine, practically all the buildings were burned, Oct. 5, as well as the shaft all the way to the bottom of the mine. Three mules in the mine were suffocated. The loss is in the neighborhood of $25,000 and it is said to be without insurance.

Illinois

Herrin—The Illinois Central strike is seriously affecting the operation of Williamson county coal mines, and many of them which are wholly dependent upon this line for an outlet, have had to suspend operations.

Streator—Negotiations have just been closed by which the Chicago, Wilmington & Vermillion Coal Company purchases in Franklin county, 6000 acres of coal rights. The land is situated between the town of West Frankfort and Ziegler.

The company proposes at once to start sinking a shaft on the property and expects soon to be turning out 4000 tons of coal per day. Another shaft will be sunk later.

Indiana

Evansville—While drilling for oil, a mile south of St. Meinrad, Spencer county, a vein of coal 5½ ft. thick was struck at a depth of 90 ft. Samples of the coal were sent to the State geologist, and he pronounced it of first-class quality. The coalfields will be developed by several shafts.

Vanderburg County

The J. Wooley Coal Mining Company, with offices in Evansville, is installing gasolene motors in the mines operated by the company, for underground mine haulage. The use of the motors and other improvements and equipments being made will more than double the capacity of the mines.

Iowa

Oskaloosa—Difficulties between employer and employees at the Excelsior coal mine have been adjusted and no Iowa mine strike will be called, as had been threatened.

Centerville—According to a decision rendered in the district court by Judge F. W. Eichelberger, the Southern Iowa Coal Company, a firm controlling the entire output of 22 coal mines along the Burlington railroad, must dissolve. The decision means an upheavel of the coal business in Centerville and adjoining counties. An appeal will probably be taken.

Kentucky

The Baltimore & Ohio, it is persistently reported, despite denials issued by officials of the road, is securing options for a road from Catlettsburg, Ky., to Jackson, Ohio. The building of this road would give the Baltimore & Ohio a low-grade line for the transportation of coal from the Kentucky fields to the Great Lakes over its own rails. This would divert considerable coal from the Consolidation Coal Company's 100,000-acre coal tract in eastern Kentucky, as the proposed line will parallel the Chesapeake & Ohio for some distance.

Clover Creek District—One of the largest transactions in eastern Kentucky coal lands in several years was consummated recently, when Louisville and Barbourville men concluded a lease of 10,000 acres in the Clover Creek district, Harlan county, from T. J. Asher. As soon as a railroad can be constructed to the property coal developments on an extensive scale will be commenced.

Ohio

Columbus—The Black Diamond Coal Company which has offices in Columbus and which operates a mine at Amesville will soon erect a new tipple and electrically equip the mine. Plans for the work are now being made.

Ouster proceedings brought by the State of Ohio against the Hocking Valley Railroad were ended Oct. 10 on the promise of the railroad company to dispose of its holdings in the Toledo & Ohio Central Railroad, the Sunday Creek Coal Company and other railroads and coal companies and to manage its business in accordance with the statutes hereafter.

New Straitsville—The Central mine, located near New Straitsville, has been leased to a company known as the Hocking Block Coal Company. The Central mine was one of the largest and best equipped mines belonging to the Columbus & Hocking Coal and Iron Company which went into the hands of a receiver about a year ago.

The Troy Coal Company, of New Straitsville, has been incorporated with a capital of $30,000.

Jackson—The Sun Coal Mining Company, of Jackson, has been incorporated with a capital of $40,000.

Nelsonville—The Monday Creek Coal Company, which was incorporated some time ago with an authorized capital of $30,000, has opened offices in the Brunson building, Columbus. The new company will operate a mine near Nelsonville, which has an output of 1000 tons daily.

Oklahoma

Muskogee—Edward Perry, of Coalgate, has sent an offer of $15,000,000 for the segregated coal and asphalt lands of the Choctaw and Chickasaw nations. It will be remembered that the Government, the guardian of the Indians, after spending $100,000 prospecting with diamond drills, reported that $15,000,000 was all the coal lands were worth. For that reason, it appears that the offer of Perry and his syndicate is worthy of consideration.

Oregon

Portland—The largest coal property now under development in Oregon is that of the Beaver Hill Coal Company on Coos bay, which sends about 300 tons into Portland every week during the winter.

Pennsylvania

Bituminous

Pittsburg—Final action was taken Oct. 10 in the absorption of the Monongahela River Consolidated Coal and Coke Company by the Pittsburg Coal Company. Transfers of stocks are being made and the deal is now consummated. The Pittsburg Coal Company has sixty mines in the Pittsburg district and employs upward of 30,000 men.

Both companies recently transferred great coking tracts to the United States Steel Corporation in a deal involving $18,000,000. It is on these properties in Washington county that H. C. Frick contemplates expending $3,000,000 for new coke ovens next spring.

Kittanning—Work has been started on the new tipple, which will be erected by the Rochester & Pittsburg Coal and Iron Company, at Lucerne. The tipple will probably be the largest of its kind in the world, even larger than the tipple of the

Buffalo & Susquehanna Coal Company, at Sagamore, which has a daily capacity of over 10,000 tons.

Anthracite

The production of anthracite coal in September was the largest ever reported in that month, 5,730,935 tons. This is an increase of 763,419 tons over the output of the same month in 1910. The production for the nine months ending Sept. 30, is 51,376,379 tons. This is the largest production ever made in the first nine months of any calendar year.

For their work in September the mine workers in the anthracite region of Pennsylvania receive an increase of 6 per cent. on the rate of wages fixed by the anthracite strike commission of 1902. The increase is applied to the October payroll.

Pottsville—The Mammoth and Seven-Foot veins of coal have been struck by diamond drillers at West Shenandoah colliery. The former is about 20 ft. thick and will mean new life to this colliery. The other is also a large vein.

It is reported that Maderia, Hill & Company, who operate mines in this region, have consummated a deal in Schuylkill county, which involves the control of the Lawrence, Bear Ridge and Stanton collieries in the Mahanoy valley. These collieries will be pumped out, extensive developments made and employment given to about 2000 hands. It is believed that these three collieries will be jointly capable of producing nearly 2,000,000 tons of coal.

Scranton—The Oxford mine with its appurtenances, located at West Scranton and belonging to the People's Coal Company, was sold Oct. 14 to F. A. B. Leach & Co., a New York brokerage firm, the legal transfer of the property having been consummated by placing on record a judgment note for $30,000. John G. Hayes, superintendent of the company, and also a stockholder, confirmed the announcement to a representative of Coal Age. Neither the People's Coal Company nor Leach & Co., would make known the amount of the purchase money, saying that it would be inopportune to do so, just at present.

Washington

Spokane—Alexander Shary, of Calgary, Alberta, who has charge of Patrick Burns' mining operations, announces that Mr. Burns will build a railroad from Calgary to his coal properties, at the headwaters of the south branch of Sheep creek, 45 miles southwest of there.

"When we started to open up the mine," Mr. Shary adds, "we were of the opinion that the ground contained only semi-anthracite coal. Ten veins of that character now have been prospected, the seams varying in thickness from 4 to 20 ft. and aggregating 160 ft. At another part of the property we have opened up four seams of bituminous coal, each from 6 to 10 ft. thick.

"Samples of the latter coal, sent for analysis to Mr. O'Sullivan, an assayer and coal expert of Vancouver, B. C., brought us the report that it was the highest grade bituminous coking coal he had ever run across. The coal contains only 3 per cent. of ash and the coke made from it runs 94 per cent. fixed carbon."

West Virginia

Wheeling—The Four States Coal and Coke Company, with operations located at Dorothy, has increased its authorized capital and is preparing to open a new mine on its property, adjoining the Dorothy operation.

Huntington—The Yawkey & Freeman Coal Company has been incorporated to engage in mining coal and manufacturing lumber. The capital stock is $700,000.

The announcement is made that the National Fuel Company, with offices in Columbus, O., has taken over the output of two mines, one located at Lynn and the other at Clothier.

Canada

Alberta

The Jaspar Park Collieries, Ltd., according to the president, Andrew Laidlow, is now in a position to maintain a daily output of 300 tons, which, by Jan. 1, 1912, will be increased to not less than 500 tons, and will be again doubled before next summer.

The property is located 205 miles west of Edmonton, Alberta, and 35 miles east of the Yellowhead Pass. It consists of 10,240 acres, covering six seams of coal, which traverse it for eight miles from north to south. The beds vary in thickness from 4 to 14 ft. Development work was started in April, 1910, and so far consists chiefly of a tunnel 3000 ft. long, which discloses a working face of coal 12 ft. 4 in. thick. A second and lower tunnel is now being driven.

The output of the mine is bituminous coal, running from 68 to 72 per cent. fixed carbon and less than 7 per cent. ash. The first carload was shipped June 15, 1911, and since that time the Grand Trunk Pacific railway has taken the entire output of the mine. A recent contract with this latter company calls for 100,000 tons of coal to be delivered as rapidly as mined.

An English syndicate, capitalized at $5,000,000, one-fifth of which is set aside for development purposes, has acquired 20,000 acres of coal land in the Copper River district, British Columbia. This announcement was made in Spokane, Oct. 9, by H. N. Galer, of Vancouver, managing director of the Royal Collieries and vice-president of the International Coal and Coke Company, who is himself interested in the land in question.

Personals

John Mitchell, former head of the miners' union, will address miners' meetings in Scranton, Wilkes-Barre and Hazleton on Oct. 30.

John F. Meagher has been promoted to the position of general superintendent of coal mines for the Birmingham Coal and Iron Company, effective Nov. 15.

H. K. McHarg, president of the Virginia Iron, Coal and Coke Company has resigned, and the directors have chosen J. B. Newton, vice-president, as his successor.

Eli T. Conner, Philadelphia, Penn., has been appointed by President Taft as a delegate to the American Mining Congress, to be held at Chicago, Oct. 24 to 28 inclusive.

H. A. Berwind, of Philadelphia, and Thomas Fisher, of Pittsburg, of the Berwind-White Coal Mining Company, with President H. Hartwell, of the Berwind Fuel Company, inspected the new $100,000 briquet plant at Superior, Wis., Oct. 10.

Ira C. Dalrymple has resigned as superintendent, Blossburg division, Tennessee Coal, Iron and Railroad Company, to accept the position of superintendent of the Mulga mine of the Birmingham Coal and Iron Company, *vice* John F. Meagher.

Announcement was made Oct. 2 of the elevation of Frederick M. Chase to the general superintendency of the Lehigh Valley Coal Company, Wilkes-Barre, Penn. Mr. Chase has been with the Lehigh Valley Coal Company for 32 years and has ranked next to the general manager since 1905.

Milton Fies, general superintendent of the coal mines of the Birmingham Coal and Iron Company has tendered his resignation from that position, effective Nov. 1. He will then go with the Pratt Consolidated Coal Company, to be in charge of Banner mines, where State convicts are to be worked on and after Nov. 15.

Dr. M. J. Shields, of the American Red Cross Society, has been recently engaged in carrying on a campaign for the Frick Coal and Coke Company, standardizing their first-aid work after the Red Cross system, and giving a course of lectures in Latrobe, Mt. Pleasant, Connellsville, Uniontown and Brownsville, Pennslyvania.

Promotions effective Oct. 1 are announced by the Consolidation Coal Company, Fairmont, W. Va., as follows: John G. Smyth is appointed manager, Elkhorn division, with offices at Jenkins, Letcher county, Ky. C. F. Ice is appointed manager Millers Creek division, with office at Van Lear, Johnson county, Ky. T. S Haymond is appointed general coal inspector, vice C. F. Ice.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The general coal trade, as predicted last week, is showing a slow but persistent improvement. While summer weather still prevails generally, local cold snaps reported from different points have had a decidedly stimulating effect on the domestic consumption.

In the East, anthracite is reported active almost without exception, with bituminous improving, or up to normal. The falling off of the lake trade in the Pittsburg district is tending to make the market there irregular, with coke still depressed and uncertain because of lack of activity at the furnaces.

Ohio reports trade the same, or improving in some districts touched by the cold snaps. Lake trade has improved but steam consumption is not up to that of previous years.

The indications of a protracted strike on the Illinois Central line, the effects of which are already being felt, is causing greater activity than the trade has seen for sometime, especially in towns entirely dependent on these lines. As a result of curtailment in some of the large mills in Indiana, notably the Gary plant with its enormous consumption, coal business there is unusually depressed.

Western States are having a good trade in both coal and coke, with every indication of still greater improvement as the season advances. Because of the strike in the Crows Nest field the northwest has been compelled to draw on San Francisco. Recent heavy water shipments have, however, placed them in a good position to meet these outside demands.

Boston, Mass.

Bituminous is slowly but surely changing for the better. The higher water rates have begun to have effect on prices for inland delivery, but no marked advance is yet apparent on coal at the loading ports. Offerings of Pocahontas or New River at less than \$2.50, f.o.b. Hampton Roads, either are no longer made or are now confined to the brands less favorably known, and to this extent there is improvement over last week in the tide-water situation. Weather conditions and slow movement have spurred the demand for contract coal and shippers are keeping close watch on their cargoes at distributing points. Were it not for quick loading, there would be some heavy demurrage bills. At Portland, Portsmouth and Providence, things are about in proportion. At one of these ports a large vessel was recently held for thirteen days. That almost no coal is being forced on the market is an encouraging feature. Another week may show an upward lift at Hampton Roads, and if that proves so, we shall know that bituminous is well on the mend. Prices at Mystic wharf, on cars, are from \$3.25 to \$3.35 for the better grades of Pocahontas and New River.

Coal from the Maryland districts, Georges Creek in particular, is coming down more freely than a week ago. A considerable tonnage is placed, in conjunction with anthracite, in Reading barges from Philadelphia, and for that delivery there is now an active demand. Rates on such hatch loads so far continue on the summer basis of 65c. to Boston; \$2.60 to \$2.70 remain the prevailing prices for Georges Creek, at Baltimore, with the usual 7c. differential up for Philadelphia.

The Pennsylvania soft coals have been in straits all season, and there is likely to be little change until the West Virginia coals definitely reach higher levels, and southern freights advance still more. Somerset county coals of high grade are offering at \$1.05@1.10 at the mines and that leaves the Clearfields rather a slim opening. The better movement of all-rail is largely to forestall the usual delays that come with the winter months. Bituminous all over is still on a low scale, and it will be interesting the next few weeks to see to just what extent it improves.

Anthracite is taking on its usual fall activity. There is a brisk demand for all sizes and dealers are refusing to guarantee prompt deliveries. The eastern dealers, and especially those up the rivers, are taking on supplies for the long season ahead, and their usual preparations are complicated this year by suspension possibilities in the spring, before the streams are again open to navigation.

Steam sizes are in good request and prices strong on all varieties. Owing to the smoke laws there is a large demand for anthracite screenings in the large cities, and in Boston the shortage has become such that within a few days the contract price to consumers was advanced from \$2.50 to \$2.75, net ton delivered with teams. The whole subject of screenings is a serious one.

Since September 1, retail prices per ton in Boston have been as follows:

Broken	\$6.75
Egg	7.25
Stove	7.50
Chestnut	7.50
Pea	5.75
Franklin	8.75
Shamokin	7.75
Lehigh egg	7.50
Bituminous	4.25

Water freights on large vessels, 3500 tons and upward, from Hampton Roads to Boston or Portland have advanced from 60c. and are now firm at 70c., with rates to other ports and on smaller tonnage in proportion.

New York

There is no spot demand in the market at the present time, for steam coal. Tonnage moving on contract, however, is quite heavy. The supply is good, there has been no slowing up as yet in railroad movement, and the car supply has been such that the mines have been in a position, with few exceptions, to work on full-time basis, if necessary.

The market as a whole, does not show the strength at this time, that had been anticipated, but the better grades of Pennsylvania steam coals are reasonably firm, owing to the substantial demand they are enjoying on contract business, and a moderate amount of new business for these grades would bring about an increase in quotations.

The market for inferior steam coals is not in such a good condition, as these coals are not sold so largely on contract, and with the spot demand at a minimum, the supply of this grade at the piers is considerably in excess, at the moment, of the needs of the market.

Philadelphia

Weather conditions here, from the coal dealer's standpoint, are far from ideal, but the anthracite is active. Orders are piling up, and in the residential part of the city, and coal wagons can be seen in every direction. A prediction of as long ago as the month of August, that there would be a rush for coal, starting about the middle of October, is being more than fulfilled. Coal dealers report an unusual demand for this season of the year, and that is saying a good deal, for the one- and two-ton lots are commencing to make their appearance, which after all cover a major proportion of the coal man's business. This demand does not seem confined to any one size. On the contrary, there is a strong market for chestnut, notwithstanding the advance in

price of this size which took effect last year, and was supposed to shift demand for this coal, which was in excess of the production, on to other sizes which were in surplus.

Hotels, apartment houses and office buildings are getting in their supplies, preparatory to the winter season, and as a consequence there is a marked increase in the consumption of the smaller sizes. Even thus early in the season, dealers hesitate about committing themselves for any specified tonnage, having no assurance that they will be able to secure sufficient to keep them supplied.

The wholesale market indicates even a better outlook than our last report. Orders are coming in thick and fast, which is but a natural reflection of the tonnage being handled by the retail dealers. All sizes are moving off. There is a slight apathy on egg, but it is understood that the individual operators show very little disposition to shade the price even on this size, so that it is not believed that there is any particular excess of this size on the market.

While it is reported that there is a fairly large tonnage of bituminous coal moving, there is a lack of snap to the market, and no general improvement over last week. Prices of the various grades of coal remain about the same.

Pittsburg

Bituminous—The market has grown more irregular owing to the lake trade's absorbing a smaller tonnage, and prices are being cut on all sales. Mine-run and nut are frequently sold down to $1 a ton, while slack is also being sacrificed, the decreased production owing to decreased shipments of ¾-in. in the lake trade not having had any effect as yet. Occasional sales are heard of as low as 30c., but these are exceptional. Demand for domestic coal is only fairly good. The nominal price for the year is $1.15 for mine-run and nut, with 10c. rise for ¾-in. and another 10c. rise for 1¼-in. We quote ordinary market prices, subject to additional shading in some instances, as follows: Nut, $1@1.05; mine-run, $1.05@1.15; ¾-in., $1.15@1.25; 1¼-in., $1.25@1.35; slack, 40@60c., per ton at mine, Pittsburg district.

The mines in the district are operating at an average of between 60 and 70 per cent. of capacity.

Connellsville Coke—Clinton furnace, in Pittsburg, will blow in about November 1, and has bought its coke supply for November and December, to run about 20,000 tons, at $1.60, ovens. The nominal asking price on contracts running over the balance of the year has been $1.70, but since early in September consumers have shown no interest in such a figure, since it was possible to buy prompt at $1.50, and the sale to Clinton, which was made by the Connellsville Central Company, indicates $1.60 as the outside price, as operators would presumably be more willing to sell for the three months, including October, than for only the two months. A few thousand tons of prompt furnace coke have been sold at $1.50. Foundry coke is very quiet as to fresh sales, but deliveries are being very well taken on contracts. We quote, at ovens: Prompt furnace, $1.50; contracts over balance of year, $1.60; prompt foundry, $1.80@1.90; contract foundry, $2@2.25.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ended Oct. 7 at 314,343 tons, an increase of 1000 tons, and shipments at 3929 cars to Pittsburg, 4669 cars to points west and 1033 cars to points east, a total of 9631 cars, a gain of 27 cars.

Columbus, Ohio

There has been a slight improvement in the domestic trade in this section during the past week, due to a slight lowering in temperature and a desire on the part of consumers to get their winter's supply of fuel stored. But the trade is not what the time of the year would warrant and coal men are speculating as to the effect of the slowness on the future trade.

Lake trade has improved in the past week. The slowness of a week ago has given away to a better movement and operators have been busy looking after Lake shipments. There is some congestion at the docks of the upper Lake ports but not sufficient to retard shipments to any great extent. Prices at the docks remain the same as during the summer. Shipments at the Toledo docks of the Hocking Valley Railroad during the past week were 85,000 tons as compared with 40,000 tons for the previous week. Shipments since the opening of navigation at the Hocking Valley Toledo docks aggregate close to 2,000,000 tons.

Operations in Ohio fields have been fairly active during the week, due to the better Lake trade and the improvement in domestic business. In the Hocking Valley field the output has been about 80 per cent. of the average and the same is true in the Pomeroy Bend field and in eastern Ohio. In the smaller fields given over to domestic trade the output has been quite large.

Retail trade is somewhat quiet in Columbus and central Ohio. There is a disposition on the part of consumers to wait until later to place orders. In the country districts farmers have been too busy with their work to haul their winter's supply. The improvement of the roads has caused this to come about. Retail prices are still firm at the usual fall schedule.

Prices prevailing in central Ohio are: domestic lump, $1.50 in the Hocking valley and $1.65 in Pomeroy Bend; ¾-in., $1.35; mine-run, $1.05@1.15 in the Hocking valley and 95c.@1.05 in eastern Ohio; nut, $1.15; nut, pea and slack, 45@55c.; coarse slack, 40@50c. Fancy grades of domestic coal are sold from $1.65@2.

Cincinnati, Ohio

Demand for both steam and domestic fuel continues about the same, with a slight increase noticeable as to the latter.

In the steam-fuel trade the market in nut and slack, both splint and Pocahontas, is weak. The latter is selling for 50@80c., with the demand so light that operators are making little effort to push the sale of the lump—at least until the present surplus of fine coal is reduced. The splint, nut and slack is bringing a variety of prices, depending upon almost every factor that might influence a transaction. A fair range of prices would be from 35@60c., although there are sales reported below the first figure, but for grades that would be under others in all but times of extreme demand. Splint block may be bought as low as 85@90c. and some is sold as high as $1.35. The mine-run brings 60@90c. The mine-run Pocahontas price is about 90c., with some sales reported at less, but under special conditions that could not be taken to determine the market. Lump brings $1.90@2 or even $2.25, depending on how badly the buyer wants it and how the seller feels about it. Practically none of it is seeking a market.

The retail prices for fuel delivered are about unchanged from what they were six months ago and have continued ever since, as follows: Smokeless lump, $4@4.25; smokeless mine-run, $2.60@2.75; bituminous lump, $3@3.25; bituminous nut and slack, $1.90@2; anthracite, $7.25, since Sept. 1, when the price was advanced 25 cents.

Charleston, W. Va.

Except for the natural increase owing to the coming cold weather, and a feeling of better prices soon prevailing there has been no change in the coal situation over a week ago. There does, however, appear to be a better feeling as to the future than for a long time, and this condition is indeed a welcome one to the coal men of the Kanawha and New River sections, who have been struggling against low prices for a long time—a condition really made by themselves, but which now has bright prospects of coming to an end.

Despite the fact that shipments have been heavy along the Chesapeake & Ohio railroad, there has been no general complaint about cars. The car distribution seems to have been very satisfactory—something that has not always existed in the West Virginia fields.

The shipment for the Norfolk & Western field was not as large in September as it was in August, but even at that it was up among the months that are near the top.

Governor Glasscock has indicated that he will be in Pittsburg about the first of November to witness the national mine demonstration, which will be held under the American Red Cross and the Pittsburg Coal Operators' Association. The governor is greatly interested in safety demonstrations, and is also a believer that an experienced person is a better individual to select inspectors than a person who is not a practical miner. This he demonstrated when he placed the appointing of all inspectors in the hands of Chief of the Department of Mines, John Laing, who himself had been a practical miner before becoming a mine owner. It will be no fault of the governor if the next Legislature in this State does not give more liberally to the Department of Mines that the greatest possible safeguards may be placed around the "men under the ground," as well as the mining property itself.

Chicago

One of the important factors of the coal trade in Chicago today is the Illinois Central strike. That it is having a marked effect on the coal business is conceded by nearly everyone except the management of the Illinois Central Railroad.

Deliveries are not being made as they should be and in some towns, dependent solely upon the service of the Illinois Central, there has been a marked shortage in the supply. Chicago coal dealers say that the chief effect felt here has been in the price of screenings. Screenings are as high as 65c. today, as compared with 35c. 10 days ago.

It is the belief of many close observers of the situation that the freight-traffic business of the Illinois Central has been seriously affected by the walkout of mechanical crafts on that system. They also prophesy that the struggle will not be ended for some time, and that meanwhile conditions will mend very slowly. There are also those who foresee a serious car shortage. A recent report of the American Railway Association showed a decided reduction in the number of surplus cars throughout the country, and it is thought by many that this curtailment will continue.

Eastern coals are just about holding their own. Lump and egg coal are somewhat weaker, the city price being about $2 to $2.10, while the country price stands at $2.25. The price quoted for Hocking Valley and splint is the same as that which has been quoted heretofore. On spot shipments direct from the mines the prices in net tons to retail dealers and steam users are as follows:

	Chicago	F.o.b. Mines
Carterville:		
Lump	$2.65	$1.60
Egg	2.65	1.60
No. 1 washed	2.80	1.75
No. 2 washed	2.35@2.45	1.30@1.75
Sullivan County:		
Domestic lump	$2.35@2.45	$1.50@1.60
Egg	2.25	1.40
Steam lump	2.10	1.25
Screenings	1.27@1.37	0.40@0.50
Springfield:		
Domestic lump	$2.07@2.22	$1.25@1.40
Steam lump	1.82@1.92	1.00@1.10
Mine-run	1.82@1.87	1.00@1.05
Screenings	1.22@1.32	0.40@0.50
Clinton:		
Domestic lump	$2.17@2.27	$1.40@1.50
Steam lump	2.00@2.10	1.25@1.35
Mine-run	1.77@1.82	1.00@1.05
Screenings	1.22@1.32	0.45@0.55
Pocahontas and New River:		
Mine-run	$3.00@3.05	$0.95@1.00
Lump and egg	4.05@4.30	2.00@2.25
Hocking Valley	...	——
1¼-inch lump	3.15	1.50
Coke:		
Connellsville	$4.50@4.65	
Wise county	4.50@4.65	
Byproduct, egg and stove	4.95	
Byproduct, nut	4.55@4.65	
Gas house	4.95	

St. Louis, Mo.

With the week beginning the 16th, everything indicates that the coal trade in St. Louis is coming into its own. There is a far better demand for coal from the country, and city business is picking up considerably. There has been a general advance in the Carterville and Franklin county prices of about 15c. per ton on lump and egg, although the price on nut has not advanced.

Standard prices are advancing a trifle, but not more than from 5 to 10c. per ton. Owing to the strike on the Illinois Central, there is very little coal coming in from mines on that road in the High Grade and Standard fields. This has caused a stiffening up of the market, and with the cold wave that arrived Tuesday, it has offered more encouragement to the trade than it has received in some time.

The prevailing prices are as follows:

Standard:	
6-inch lump	$1.05@$1.10
2-in. lump	0.95@ 1.00
Mine-run	0.85
No. 1 nut	0.80
No. 2 nut	0.65
Screenings	0.30
Carterville:	
6-in. lump	$1.50@$1.60
3x6 egg	1.50@ 1.60
No. 1 nut	1.15@ 1.20
No. 2 nut	1.00@ 1.10
Screenings	0.40
Mine-run	0.95@ 1.05

The Franklin county prices are approximately 15c. per ton higher in the St. Louis market than the Carterville prices.

Murphysboro Big Muddy lump and egg is strong at $2.10. The last mentioned coals take a rate of 67c. to St. Louis, and the Standard coals a rate of 52c. to St. Louis.

The higher grade coals from the Standard field, such as Trenton, etc., are still holding their own at about $2. The middle-grade Standard coals are still holding at from $1.25 to $1.35 for lump and egg, and the other sizes going at what the market will give.

Everything seems to indicate a good movement of coal from this time on, and the car shortage troubles on roads like the Iron Mountain and Illinois Central, and the lack of motive power on the C. & E. I. will boost prices on those roads and help the other coal-carrying roads in the way of tonnage.

Minneapolis—St. Paul

The volume of retail trade in the Twin Cities at this time is satisfactory. The weather has been cold and rainy, and it has been necessary to keep furnace fires going.

Prices for domestic coal are fairly well maintained, but on all steam sizes, including Youghiogheny, Hocking and splint screenings, it cannot be said that there is an established price. Smokeless run-of-mine is also sold considerably below list. This unfortunate condition exists because the wholesale companies last spring inaugurated a campaign for tonnage.

One thing noticeable this season is a more liberal supply of nut-size anthracite at the head of the Lakes. Last season, an attempt was made to curtail the demand for chestnut by advancing the price 25c. per ton, thinking that it would turn the demand toward stove size. But it had no such effect, and the anthracite operators are sending a larger percentage of nut size into the Western trade, with the result that all dock companies are easy on the nut size.

This change is accounted for by the fact that when the advance of 25c. per ton on chestnut size was made effective in the East, it did have the desired effect and the consumer turned to stove- and egg-size coal, until the operators cannot fill the demand for the egg size, and the chestnut size became a drug on the Eastern market.

Denver, Colorado

The domestic mines of Colorado were not favored during the past summer with business to absorb more than 60 to 65 per cent. of their capacity, due largely to extended drought and crop failures which affected to a greater or less extent the entire territory served by these mines. During the winter of 1910-1911 purchases of coal were in excess of the demand owing to the exceedingly mild weather. With this surplus on hand and an apparent shortage of crops, the trade reluctantly placed orders early for but a small percentage of the usual requirement. The season's advance brought little relief and the desired increase was not manifest. Prices remained firm throughout the period notwithstanding the light volume of business.

The winter prices were effective Sept. 1 and the advance over the previous month naturally had a tendency to make orders light for immediate shipment, but the

whole production of the mines has been but little under that of the same month in other years. Orders are being freely filled at present for shipments to be distributed during the balance of the year and 50 per cent. of the total winter production has already been contracted. Recent reports from all over this territory show much improvement and while no abnormal increase has been predicted, a busy season is anticipated.

During the summer season, cars were plentiful. The fall trade has, however, utilized this surplus and there is every indication of a shortage of railroad equipment due to an extremely heavy fruit crop. The local railroads have a great many cars with their connections which further adds to their immediate distress. There has been no serious delay reported at the mines as yet due to shortage of cars, but the outlook for the future with a normal booking of orders is not exceptionally promising.

The labor supply has been adequate but with the advent of full time this condition will doubtless be reversed as is borne out by the history of previous years.

The steam trade during the past summer has been fair, considering the light volume of business done by the Western railroads and industrial institutions.

The coke trade during the past summer has been good owing to a heavy demand at the steel works in Colorado and the smelters and foundries in Montana, Colorado and the Southwest taking their usual summer requirement. Orders are gradually increasing with future prospects promising.

New Mexico

The mines of eastern New Mexico rely, for their market, principally on the south portion of the territory reached by Colorado shippers with practically no advantage over Colorado in transportation facilities and as the drought in this territory has been exceptionally severe and railroad traffic exceedingly light, a low production has been reported for the last four months. The steady upward trend in general business is evidenced by an increase in orders and preparations are being made to take care of a heavy fall and winter trade.

The western New Mexico mines report a prosporous summer season with prices firm throughout the period. All mines worked full time, due to a wide range of territory and favorable existing conditions. The advance in price Sept. 1 had no adverse influence on the volume of orders being placed. A slight shortage of railroad equipment has recently been indicated, but this condition is believed to be only temporary. More labor could be used to advantage, but from reports of former years this proves to be the rule rather than the exception. The isolated location of these mines has always operated against a ready supply of labor.

Salt Lake City, Utah

With the cold weather fast approaching the situation of the Utah mines and dealers is assuming a serious aspect. As was reported last week, the mines are working half time or less, and they are from two to five weeks behind in filling orders.

The relief promised by the Denver & Rio Grande road in increased motive power and cars has not as yet been in evidence and from the inside it is quietly given out that none is to be had this year. It is said that the Utah Fuel Company's production at Castle Gate and Clear Creek, has fallen off to such an extent, that next year will see the company kept almost entirely busy in furnishing coal to the Denver & Rio Grande and Western Pacific roads, with which it is closely allied.

Another feature, in this same connection and which affects the local market, is that strenuous efforts are being made by the Gould interests, to build up a traffic for the Western Pacific, and that the California coal business is being worked to the limit in order to give the road the long haul from Utah to California points.

Salt Lake dealers are all using about 75 per cent. reserve-stock coal in order to fill their orders, which are not big, owing to mild fall weather.

San Francisco

The arrivals for the past week have been as follows:

	Tons
Coal from British Columbia	15,110
Coal from Washington	2,590
Coal by rail	300
	18,000

Our anticipations, as expressed last week, are now being realized. The retail trade is taking advantage of the good weather conditions that prevail, and the storage of coal for winter use is now the order of the day. The market is in a good, healthy condition, and we are looking forward to a brisk demand and profitable business during the next five months, which are included in our wet season.

The deliveries by rail are not up to the usual quota for this season of the year, which is doubtless due to a continuance of the railroad strike and the fact that the Northwest is drawing from our sources of supply, to replenish stocks that have been exhausted because of the strike in the Crows Nest (Canada) district.

There is no change in prices from those of last week.

Spokane, Wash.

Reviewing the local situation E. F. Waggoner, president of the Union Fuel and Ice Company, said, Oct. 9, "There seems to be plenty of coal available to take care of immediate demands." Prices for best domestic lump and nut, \$8.25@9; steam coal, \$6.25; Pennsylvania anthracite, \$17.50. These quotations are lower than for September and October, last year. Dealers are storing very little coal, and no shortage is anticipated here during the coming winter.

The demand for coal by Western railroads is less than during the year previous, as many of the roads are using oil burners. This has given larger available supply for domestic and steam purposes.

C. A. B. Jackson, of Toronto, Ont., formerly a coal-mine operator at Frank, Alta., said, on returning from Crows Nest district, that the strike of the miners is about over. Operators informed him they expect the men to return inside of two weeks on the open-shop basis, and the international union is reported to have stopped all strike benefits. The smaller mines are working full capacity.

Portland, Ore.

The weather is such that there is little demand for coal just now, the winter prices having gone into effect Oct. 1., which means an increase of \$1 per ton over those quoted prior to that time. Coal dealers here say that the consumers are gradually becoming educated to the fact that they can save \$1 per ton by placing their orders during the summer or fall months of July, August and September and that as a result a great deal of coal is being put in during those months. The great advantage of this is, as every coal dealer readily realizes, that during the cold winter spells it relieves them of an avalanche of business during a few weeks with nothing to do part of the year. It is said that this summer more consumers placed their orders than in any previous year.

The weather is almost spring-like here, balmy breezes and clear days, with occasional showers, and as a result the consumer who buys half a ton or a ton of coal at the time, has not yet made his appearance to any marked extent.

British Coal Market

Tonnage arrivals were again very scanty, and the market is easier for prompt shipment. Quotations are approximately as follows:

Best Welsh steam coal	\$3.96
Seconds	3.72
Thirds	3.60
Dry coals	4.02
Best Monmouthshire	3.72
Seconds	3.60
Best Cardis small steam coal	1.98
Seconds	1.86

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage, and for cash in 30 days, less 2½ per cent.

COAL AGE

Vol. 1 NEW YORK, OCTOBER 28, 1911 No. 3

"Aff agin, on agin,
Gon agin, Finnegan."

Such an oft reiterated story as the one given under the above title hardly needs repeating.

Some years ago when railroad equipment left the rails, with frequency because of—well, because there wasn't any provision to keep it on, the railroad authorities called for reports from the road foremen.

Some of these, being neither machinists nor engineers, and having no great skill in the writing of essays on track mismanagement, resented the literary effort demanded of them, though it must be conceded that they knew a lot about mishandled track; in fact, it might be succinctly stated that they didn't know about any other kind of track, for mismanagement ruled the day.

There was one, Patrick O'Finnegan, who firmly believed "the divil put the cars aff and 'twas Patrick put them on agin" or incinerated them if they were beyond salvage.

Said Patrick had a derailment on his section; he retracked the cars, wetted the point of a pencil and proceeded to write his version of the wreck on the elaborate form provided by the company, in the exact language of the heading of this article,

And Pat was satisfied, believing his last duty was done; he was surprised, therefore, when the "White Shirts" in New York returned his reply for further elaboration. The cars were off, he had them back on the track, and "divil a bit was there then to be said."

—o—

Now if Pat had been working underground, not 25 years ago, but today, it's probable that not only Pat, but the "White Shirts" in the main office would have felt all was done that should be done.

Derailment in the mine rarely takes a life, but it does destroy the track and cars and wastes valuable time. Again and again it will occur at the selfsame place, and the foreman says it can't be helped, puts the cars back on the track with a pry, a few blocks, much grunting and a pinched finger or two. "Well, they're on again," and when he sees the superintendent, he explains his loss in tonnage by saying: "Another wreck. I'll do better tomorrow."

—o—

There're too many Finnegans in charge underground who ought to be sextons in cemeteries or janitors in county court houses. There's no job in the mines where they're needed.

Be sure, Mr. Foreman, you inquire where, why and how that car was detracked and remedy the evil.

You say you have too many miles of track to watch. Perhaps you have; probably that's your fault. But I doubt if you've got so many it wouldn't pay to have them clean, ballasted, lined up true, free of humps, with even joints, perfect gage and no sharp curves.

Look at your equipment. Have you heavy, well spiked rails, supported by good ties, joined by fishplates? Are all the unnecessary frogs and switches ripped out?

And the cars. Do they run on three wheels and carry the fourth like a pointer on a hunt? Are they prone to knuckle up or down, right or left? Have they straight axles, true wheels and correct gage?

—o—

Oh! by the way, hang this colliery note in your den, "DERAILMENTS—A PREVENTABLE DISEASE."

Electrical Machinery for Coal Mines

By Sydney F. Walker*

The shunt-wound continuous-current motor and the three-phase induction machine are described and compared. Particular reference is made to their government and speed regulation in connection with various classes of colliery work.

*Bloomfield Crescent, Bath, England.

When electricity was first applied to the working of coal mines, continuous-current, or direct-current apparatus, as it is often termed, was employed, because it was the only apparatus on the market. In those days, although alternating currents were in use for town lighting, it was only single-phase currents that were employed, and the single-phase motor was not then suitable for mining work. The single-phase motor has been enormously improved during the last 15 years or so, and at the present time there is a keen struggle between it and the continuous-current motor, in regard to the driving of electric locomotives for urban and inter-urban traffic.

It is claimed by the advocates of the single-phase motor that it is more economical, and possesses certain other advantages over the continuous-current motor. On the other hand, it is very much more complicated in construction than either the continuous-current motor or the three-phase alternating-current motor that has come largely into use for coal-mining work; and so far as the writer is aware, no attempt has yet been made to adopt it in mining work of any kind. It may be mentioned, by the way, that the single-phase alternating-current motor is merely a modification of the continuous-current motor. It is a continuous-current motor, having the familiar commutator and also a special arrangement for delivering alternating currents to the coils of the motor, and special windings which enable it to perform, with single-phase alternating currents, the service ordinarily required of continuous-current motors.

Recent Gain in Popularity of Three-Phase A. C. Motors

During the last 10 to 15 years, three-phase alternating-current apparatus has been gradually displacing continuous-current apparatus. There are several reasons for this, but the principal one is the absence of the commutator which forms such an important part of the continuous-current motor and generator. The modern forms of continuous-current and three-phase alternating-current motors, are very similar in outward appearance. In each of them there is an outer containing cylinder, sometimes of magnetic steel, sometimes of wrought iron, sometimes of cast iron as shown in Figs. 1 and 2.

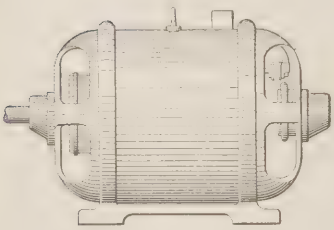

Fig. 1. Continuous-Current Motor

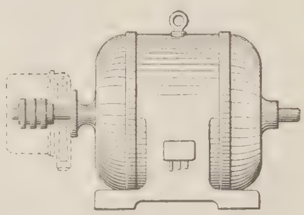

Fig. 2. Three-phase Induction Motor

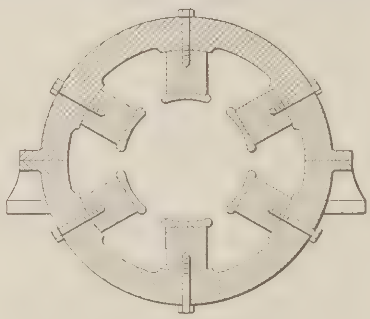

Fig. 3. Vertical Section through Field of D. C. Motor

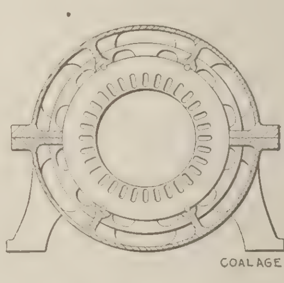

Fig. 4. Sectional View A. C. Motor

In the continuous-current motor, the electro-magnets which create the magnetic field in which the armature revolves, project radially inward from the containing cylinder, as shown in Fig. 3. Their cores are constructed usually of laminated iron, held in various ways to the containing cylinder, sometimes cast in the cylinder, sometimes held by other mechanical means. The coils containing the wires which create the magnetic field, are slipped over the cores of the field magnets, as they project inward, and crescent-shaped pole pieces are attached to the inner ends of the cores. These pole pieces more or less completely inclose the cylindrical space in which the armature revolves.

In the three-phase alternating-current motor, there are a number of thin disks of either wrought iron, or mild steel, or some form of iron or steel that will readily receive and give up magnetism, built up on the inside of the containing cylinder, so as to form a drum. Slots are made in the disks before they are placed on the inside of the cylinder, to hold the wires which carry the alternating currents. The drum formed by these disks incloses the cylindrical space in which the rotor, which corresponds to the armature of the continuous-current machine, revolves as shown in Fig. 4.

Similarity of D. C. Armature and A. C. Rotor

The armature of the continuous-current motor, and the rotor of the three-phase alternating-current motor, are also very similar up to a certain point. Each is built up of a number of thin disks of either soft iron or steel, material that will receive and give up magnetism quickly. The disks are slotted for the reception of the wires, which will cause the revolution of the armature or rotor, when the machine is working. The disks of the armature, the rotor, and the stator, as the drum inside of the containing cylinder of the three-phase alternating current motor is called, are all insulated from each other by being dipped in an insulating varnish before being strung together.

In both the continuous-current armature, and the three-phase alternating-current rotor, wires are laid in the slots. In the case of the continuous-current armature, however, the wires are in certain lengths and the ends of adjacent lengths, or coils, are connected to the segments of the commutator. The coils are all of the same length, are all placed in the slots and on the drum in the same way, and are insulated from each other, and from the iron in the slots of which they lie. This is shown in Fig. 5.

In the three-phase alternating-current rotor, there are two arrangements of the wires or conductors, known respectively as the squirrel cage and the wound rotor. In the squirrel-cage rotor, the conductors which lie in the slots of the iron or steel drum, are usually bars of copper, sometimes laminated. The bars are insulated from the iron and from each other, and

they are connected at each end to a ring of copper; the whole arrangement of the conductors, when viewed free of the iron drum, being similar to the well known cage in which squirrels are made to perform. Fig. 6 shows a section of such a rotor.

In the wound rotor, the conductors are usually smaller, more of them are laid in the slots, and they are wound on very much the same lines as the armature coils of a continuous-current motor except that there are three sets of coils instead of one set. The special feature of the wound rotor is the arrangement that is made to insert electrical resistances in the circuits of the coils, during the starting period. For this purpose, rings of copper are carried on the rotor shaft; carbon brushes bear upon the rings, and the arrangement is such that during the starting period, a connection is made between the coils of the rotor and certain resistances provided for the purpose. These resistances are cut out as the machine gets up speed, and when the speed is normal, the brushes are thrown off and the arrangement of the coils becomes practically the same as that of the squirrel-cage rotor. Fig. 7 shows a longitudinal section of a wound rotor with slip rings.

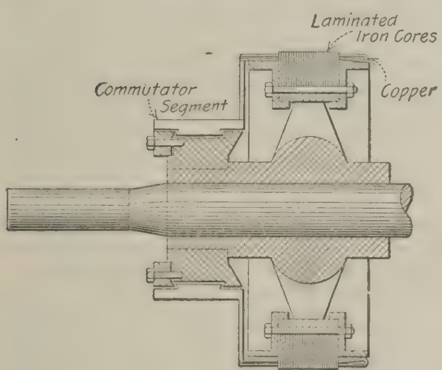

Fig. 5. Sectional View of Continuous-current Armature

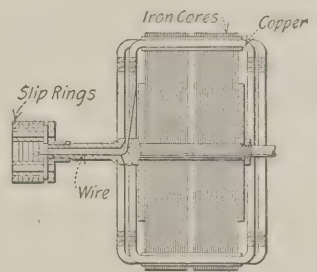

Fig. 7. Sectional View of Wound Rotor

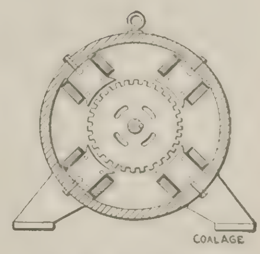

Fig. 8. Sectional View of D. C. Motor

Operation of the Two Types of Motors Compared

The working of the two machines is quite different, though the effect is the same. In the continuous-current motor, brushes bear upon the commutator. The commutator is a cylinder built up of segments of copper, insulated from each other by mica; the individual segments, as explained above, being connected to the ends of adjacent coils on the armature. The coils of the armature are so arranged that there is a continuous path or, as it may be termed, a continuous loop through all the wires by way of their connections to the segments of the commutator.

When the continuous-current motor is running, current is delivered from the electrical service to the brushes, from them to the segments of the commutator, and thence to the armature coils. Current is at the same time delivered to the coils surrounding the field magnet cores. The two sets of currents, that passing in the armature coils and that passing around the coils of the field magnets, create magnetic fields in the cylindrical space in which the armature revolves, of such a nature that attractions and repulsions are set up between the two and the result is that the armature turns in a certain direction, and continues to turn in that direction, as long as the current is flowing.

In the three-phase alternating-current motor, the slots in the drum formed on the inside of the containing cylinder, carry coils which receive the three-phase currents from the electrical service. There are three sets of coils, each set of coils receiving current from its own conductor, representing a particular phase. The delivery of the currents to the coils in the stator, as it is termed, is so arranged that currents are induced in the coils on the rotor, whether it be of the squirrel-cage or wound-rotor form, in such a direction that attractions and repulsions are set up between the two sets of magnetic fields, those created by the currents in the stator coils, and those created by the currents in the rotor coils, so that the rotor commences to revolve in a particular direction, and continues to revolve as long as currents are supplied to the stator coils.

Distinction Between the Magnetic Fields

The broad distinction between the magnetic fields created in the cylindrical space in which the armature of the continuous-current motor revolves, and those created in the cylindrical space in which the rotor of the three-phase induction motor revolves, will be noted. In the continuous-current motor, there is one magnetic field, of definite strength and of definite direction, created by the currents in the field magnet coils. There is another magnetic field created by the currents in the armature coils; and the motion which is given to the armature is due to the interaction of these two fields.

In the three-phase alternating-current motor, there are several magnetic fields created by the currents passing in the stator coils, and there are several magnetic fields created by the currents in the rotor coils. As mentioned above, there are three sets of coils, and three sets of currents in the stator. Each set of coils receives its currents in succession. Those connected to, say, No. 1 phase, receive their currents first; a little later those connected to No. 2 phase; and a little later again those connected to No. 3 phase receive their currents. In each set of coils, the currents are rising and falling and reversing, and all of these operations are taking place in succession in each set of the coils; the result is that what has been termed a revolving magnetic field is created within the cylindrical space in which the rotor revolves.

An eminent American electrical engineer has compared the action to that of a cat chasing its tail. A magnetic field of a certain strength arises at different points all round the cylindrical space in which the rotor revolves; the strength of the magnetic field so arising gradually increases, then gradually decreases, dies away and then reverses. Meanwhile the currents of the next phase commence to create another field just in front of the first, which increases in strength to a maximum and dies away just as the first did; then the third set of currents takes up the running, creates another field in front of the second, and so on.

The currents which arise in the coils of the rotor are really due to the same cause as in the static transformer. It is the rise and fall and reversal of the currents in the stator coils, which induce currents in the opposite direction in the rotor coils. These currents rise and fall and reverse in exactly the same order.

Simple Construction of the Squirrel-Cage Motor

It will be seen that the squirrel-cage form of the three-phase alternating-current motor, is simplicity itself. There is only the containing cylinder, the stator drum with its coils on the inside of the cylinder, and the rotor with its shaft and coils. There is nothing in the nature of

a commutator; there is no electrical connection between the rotor and the stator. The question of starting squirrel-cage rotors will be dealt with separately; but when the squirrel-cage motor is running, there is, or should be, nothing to get out of order.

On the other hand, with the continuous-current motor, the commutator and the brushes require frequent attention. With modern machines the attendance is very much less than was required in the early days, but nevertheless, the commutator is a solid disadvantage, when compared with an apparatus of the squirrel-cage type, which has no commutator and nothing that can be compared to one.

Disadvantages of the Commutator

The commutator may be said to have two disadvantages. Even the best forms of the latest construction require truing up from time to time, and brushes require renewing and regulating. The more serious objection, in the case of coal mines, is the possibility that an explosive mixture may be present in the neighborhood of the commutator. From experiments which have been made, it would seem that it is not easy to fire an explosive mixture at the commutator, but such a thing may happen, and at many collieries this possibility has led mining engineers to look askance at commutating motors for driving coal-cutting machines, etc. In the coal-cutting machine, the motor is necessarily inclosed, the commuutator being out of sight, while at the same time it is difficult to prevent coal dust finding its way to the surface of the commutator and where coal dust is present, it may lead to wear of the surface of the commutator, and to sparking.

There is also another and perhaps more serious danger in this connection. The brushes are held upon brass spindles attached to some part of the framework of the machine. It is necessary that the spindles shall be insulated electrically from the framework, or whatever they may be attached to. If they were not insulated, a short circuit would be created from the positive to the negative brush, and no useful work could be done by the motor. The insulation consists usually of rings of various materials, micanite being a favorite. In the early days of dynamos and motors, vulcanite and vulcanized fiber were used. Whatever the substance may be, there is always the danger of a deposit of coal dust, of carbon dust from the brushes, and of copper dust from the commutator, forming upon the surfaces of the insulating rings. A film of dust formed in this way, may lead to a dangerous arc. Nothing usually happens until a certain quantity of dust has been deposited, and then suddenly when the current is switched off, or when a large portion of the load is thrown off the motor, a spark may pass across the surface of the insulating ring, burning up the dust and causing a flash, which may possibly be followed by an arc.

The Induction Motor also Has Disadvantages

On the other hand, the three-phase induction motor has certain disadvantages. In the ordinary squirrel-cage form, with heavy copper bars, the starting torque, that is, the effort which the rotor is able to exert at starting, is small, and hence it is necessary to start upon no load, or to provide special arrangements, which tend to complicate the machine. In the case of coal-cutting machines, for instance, it frequently happens that heavy starting torque is required. With bar and disk and chain machines alike, it is more convenient if the machine can be made to start up in the cut. The ordinary squirrel-cage motor will not do this.

In addition, it often happens when cutting along a coal face, that a piece of very hard strata is met with. The continuous-current motor will exert practically any amount of power that may be required. It is a good natured horse, and will go on striving to deal with the load in front of it, even to the point of burning itself up. With the three-phase induction motor, a certain amount of additional work may be got from it by slowing up, and it necessarily slows up when faced with additional resistance, but there is a limit beyond which the motor will not go. It is an open question whether this is an advantage or disadvantage. It is very annoying to have the machine stop just when it is most wanted to put forth its best work. On the other hand, it is very annoying to have the machine put forth its best work, and to be useless afterward, as the continuous-current motor may be.

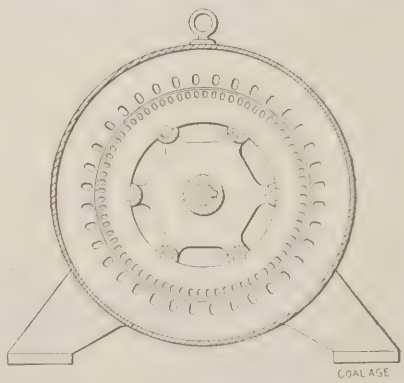

Fig. 9. Sectional View of Induction Motor

The Necessarily Small Air Gap a Disadvantage of Induction Motors

There is a further drawback to the use of the three-phase induction motor. In order that a high efficiency may be obtained, that is, in order that the largest possible proportion of the electrical energy delivered to the motor shall be obtained as mechanical energy at its axle, it is necessary that the rotor shall run very closely indeed to the stator drum. With every class of motor, whether continuous-current or alternating, it is an advantage for the moving parts to run very close to the stationary parts; but with continuous-current apparatus, the result of allowing greater space between the fixed pole pieces and the moving mass of the armature has not such a great effect upon the efficiency, as has a similar clearance between the stator drum and the rotor of an alternating-current machine.

With the continuous-current motor, a clearance of 1/16 in. is quite common, 3/32 in. is also often employed, and I much prefer as much as ⅛ in. With the three-phase induction motor, 1/32 in. is as much as can be allowed. This means that a very trifling wear of one bearing, or both bearings on one side, owing to a tight belt, for example, will cause the rotor to rub upon the iron of the stator, with the result that the machine is broken down. Figs. 8 and 9 show the difference between the clearance in a continuous-current motor and a three-phase motor.

In subsequent articles, I propose to deal with other points in connection with this subject.

Immunizing Coaldust by Water and Ground Rock

A brief report of the conclusions of the *Comité Central des Houillères de France* from experiments at the Lièvin gallery, printed in the *Annales des Mines*, September, 1910, page 227, contains among observations which are, by this time, trite reflections of mining men, a few important considerations.

A naked flame or electric arc, in the absence of firedamp, is less likely to start an explosion than a blown-out shot of a non-permissive explosive.

The amount of water needed to render coal-dust inexplosive is a weight of the former equal to the weight of the dust which it is designed to render immune from explosion. When it is purposed to immunize by the use of powdered rock, not less should be used than half as much rock as of coal dust, which it is desired to render inert. The dust of coal as referred to in the above is defined as being all fine coal, 2 mm. (0.078 in.) in diameter or finer. The dust for immunizing should be of extreme fineness and in estimating it, the ash of the coal should not be considered, as its action is uncertain. To stop an explosion in a wet zone, the admixture of water should be four times the weight of the coal dust to be rendered inert.

Preparation of Anthracite Coal

By M. A. Walker

Methods used in the Panther Creek region where there is much large rock present in an otherwise singurlarly pure coal.

In this section of the anthracite field the dominant factors in the preparation of coal are the presence of a large quantitiy of rock, in pieces often running up to as high as 800 lb. in weight, and comparative freedom from "bone" in the coal as it comes from the mines. The high proportion of big rock in the run of mine coal is responsible for a style of breaker construction which does not obtain in the northern and middle fields. The low proportion of "bone" practically reduces the problem in many instances to one of eliminating the rock.

In general, the preparation plants here consist of two distinct buildings: The head house and the breaker proper. The function of the head house is to remove all the large pieces of rock and as much small rock as possible down to and including that of steamboat coal size; also to render the coal of suitable size and condition for reception into the breaker. The head-house product is carried to the breaker as a rule by conveyers of either the scraper or carrier type. These are often inclined in order to gain the necessary hight at the breaker end and frequently 250 to 300 ft. in length. All jigging, final sizing and picking of the coal is confined to the breaker.

A Typical Plant

Fig. 2 is a diagram showing the run of coal in a scheme of preparation typical of this region. Tables 1, 2 and 3 are compiled from data relating to the Lehigh Coal and Navigation Company's breaker at Coaldale, Penn. This is a modern plant which has been in successful operation for nearly two years and may be taken as representative of the locality. It has a demonstrated capacity of 1350 mine cars per day from which it prepares about 3500 tons of coal with 118 men at a labor cost probably not exceeding 10c. per ton. From 10 to 12c. a ton is an average labor cost for this region which compares with 6 to 8c. in the Wyoming region, where large rock is not a factor.

It will be noted from Fig. 2 that the scheme of preparation in the head house is in general as follows: A disposition of the mine rock is made, when necessary, at the dump by means of a by-pass gate *A* in the bottom of the dump chute. The coal stream from the dump is passed over the platform shakers *C* having 6-in. round mesh, and a consequent separation made into two streams, one of lump size, the other of mixed steamboat and smaller sizes. Following first the lump-coal stream, it is seen to descend to the picking tables *D*, which are about 20 ft. long and have a pitch of 2 to 2¼ in. in 12 inches. Here all the rock is removed and the cleaned lump coal which passes off is broken down in the crushers *H* to steamboat size and smaller. Steamboat size is removed by the shakers *F* which have a 4½-in. round mesh, and is subsequently rebroken. All of this stream goes to that one of the two conveyers which is devoted to cleaned coal.

Following next the second stream, which consists of everything passing through the 6-in. mesh of the platform screens, it is found to be led over the shakers *E*, having a 4½-in. round mesh. The steamboat coal thus made is hand picked, then crushed and taken to the clean-coal conveyer. Everything passing through the mesh of the shakers *E* is led directly to what is known as the "dirty" coal conveyer, to distinguish it from its partner.

Fig. 1. Coaldale Breaker, Lehigh Coal and Navigation Company, Coaldale, Penn.

Preparation in the Breaker

There are thus two streams of coal passing up to the head of the breaker; one cleaned, the other not cleaned, and both a mixture of broken and all smaller sizes, except when it is desired to ship steamboat size, which is done by omitting to break down that size in the head house. The clean-coal stream is usually sized over two sets of shaking screens similar to those listed in Table 1, and is passed from them directly to the pockets with more or less examinatron in the chutes.

The dirty-coal stream is sized over four sets of shakers, or as a rule, double the number used for the clean coal, similar to those listed in Table 2. Broken size from these screens is usually cleaned by spiral pickers or some other mechanical device, supplemented more or less by

hand picking; occasionally it is jigged. Egg, stove, chestnut and pea sizes are usually led directly from the screens to the jigs. It is the practice in some breakers, however, to spiral or otherwise mechanically pick these sizes on their way to the jigs, and it depends a great deal on local conditions whether or not a profitable percentage of pure coal can thus be deflected to the pockets. Buckwheat size is jigged in a number of cases, but more often it passes directly from the screens to the pocket, as do also the rice and barley sizes.

Table 3 gives data relating to jigs of the "Lehigh Valley" plunger type, shown in Fig. 3, which are replacing other styles in a good many instances. The jigged coal is thoroughly examined and occasionlly resized before passing to the pockets. The usual provisions are, of course, made for breaking down the material rejected at the jigs and various picking places and for resizing and cleaning the same.

Rehandling Condemned Coal

There is today a very marked tendency toward more rigid standards of inspection at the collieries and a consequent prominence to the subject of rehandling condemned coal. Exact figures of general interest in this connection are hard to obtain, but it may be easily observed that rehandling condemned coal is liable to be a very expensive operation unless it is possible to pass it through the breaker while at the same time working on coal from the mines.

The disposition of refuse is a particularly important part of the subject in this locality for the reason that, as already observed, there is a large quantity of rock in the coal as it comes from the mines, of which a very considerable portion is in pieces of great size and also because the topography of the region makes it necessary to deposit all this material on the mountain sides, frequently at a considerable hight above the breaker.

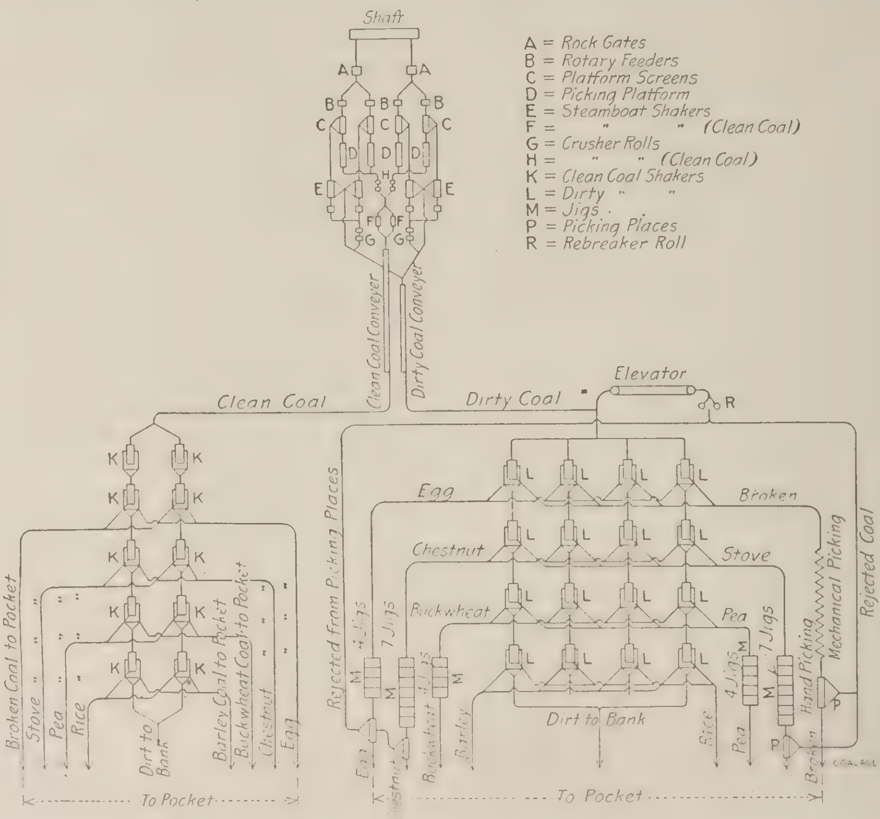

Fig. 2. Diagram Showing Run of Coal

TABLE NO. 1. PURE COAL SCREENS

At one plant the head-house rock and the breaker refuse are brought together by conveyers to a pocket which loads a skip hoist or "gunboat." This travels on an inclined plane and discharges into a pocket at the top from which are loaded trips of dump cars. The latter are then conveyed by a steam locomotive along the summit of the rock bank and dumped.

Disposition of Rock

Generally, however, it is found possible to omit one or more links in this series and the usual plan for handling refuse is to have two large rock chutes in the head house, each of a capacity sufficient for at least a half-day's run, and discharging into dump cars which travel to and from the rock bank. It may or may not be necessary to elevate these cars to the summit of the rock bank; in case it is, this is usually accomplished by an inclined plane and "barney" car. The breaker refuse is usually delivered to the same dump cars that take the head-house rock by means of a conveyer discharging through a loading pocket. In general the disposition of refuse adds a labor charge of from 3 to 4c. to each ton of coal shipped.

A matter which is probably receiving more attention than any other one thing in connection with the subject of coal

preparation in this district, as well as in other parts of the anthracite field, is the prevention of breakage in the chutes. Nearly all of the larger companies are continually experimenting on different forms and styles of chutes with various results and varying degrees of success.

One of the chief difficulties in connection with the building of a permanent chute, is the fact that the quality of the coal is likely to vary from wet to dry and from clean to dirty, in the sense that a large proportion of fine coal constitutes dirt as well as a large proportion of impurities. The same pitch of chute is not suited to both conditions, and in consequence the clean, dry coal is liable to go down with a bang, while the wet, dirty coal lags on the way.

To a limited extent, this difficulty has been overcome here, as elsewhere, through the use of retarding chutes, which operate on the principle of allowing the pieces of coal to expend their acquired momentum at frequent intervals by sliding up a slightly adverse pitch. These chutes are constructed in zigzag fashion, with comparatively short straightaway runs, and when built with enough pitch on the straight runs to suit the slowest coal likely to traverse them, they have here been giving excellent results within certain limits of application.

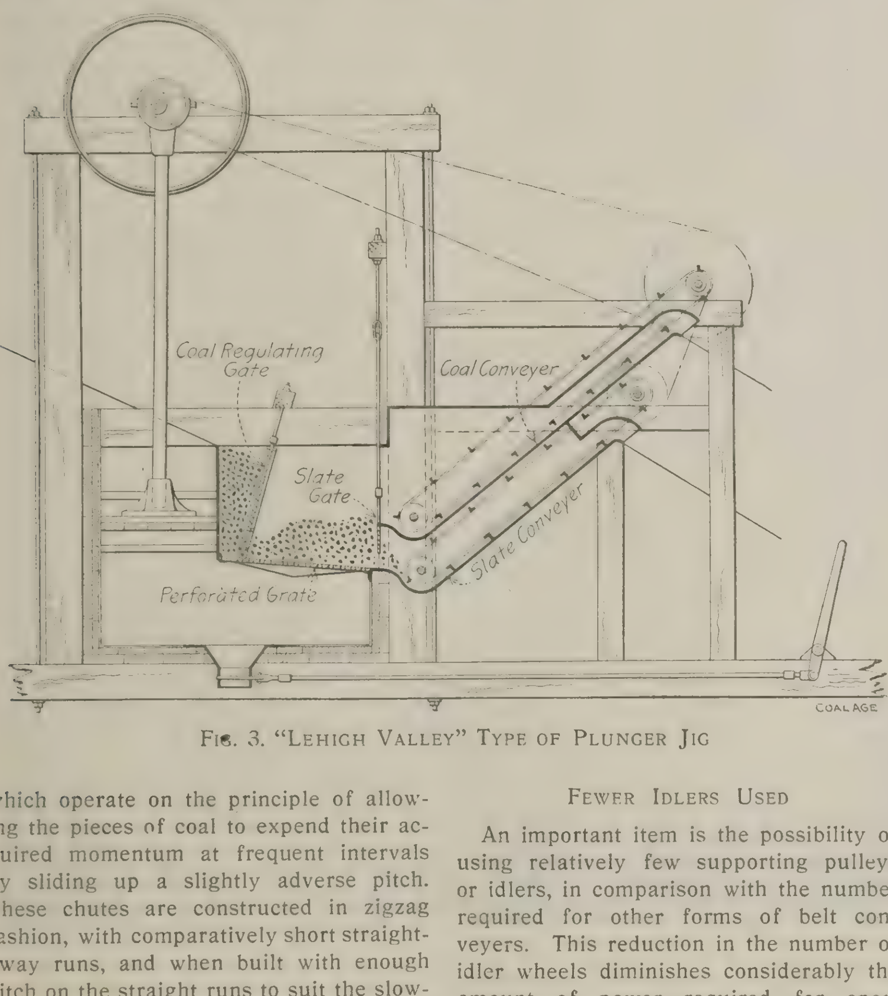

FIG. 3. "LEHIGH VALLEY" TYPE OF PLUNGER JIG

The modulus of elasticity of a hoisting rope varies during its working life, being small at first and afterward increasing to nearly the value of the modulus of the wire itself. If the rope is kept in use long enough, it will decrease. When this decrease is observed, the rope is deteriorating.

Steel Belt Conveyers

After several years of experimenting, a Swedish steel company has succeeded in manufacturing a steel-belt conveyer, which has given most satisfactory service in various plants of northern Sweden.

These steel-belt conveyers are made in lengths of 100 m. (328 ft.) and are 200 to 400 mm. (8 to 16 in.) broad, and 1 to 1½ mm. (0.04 to 0.06 in.) in thickness. To obtain a special length or width, two or three of these standard sizes are riveted together. They are made of high-grade charcoal steel, possess a high resistance against wear and tear and are extremely flexible.

These conveyers are used for transporting all kinds of material, and it is said are cheaper to manufacture and install than high-grade belts of other material.

Fewer Idlers Used

An important item is the possibility of using relatively few supporting pulleys or idlers, in comparison with the number required for other forms of belt conveyers. This reduction in the number of idler wheels diminishes considerably the amount of power required for operation. The maintenance cost of these conveyers is low, and repairs are easily made by riveting on a new piece of the required size.

A troughing of the belt itself is impracticable, and it is made to run in a guide channel or trough, which may be of steel, or wood covered with steel. The sides of this trough should be inclined at a slight angle to the plane of the belt. A longitudinal elevation of these conveyers as they are installed shows the upper or carrying run to be slightly convex. This is done to keep the belt in the guide trough in the event of material piling up along the conveyer.

Ordinary wooden pulleys, the faces of which are covered with a ⅛-in. to ¼-in. layer of rubber, give excellent service as driving wheels. When cast-iron wheels are used their faces should also be covered with rubber. The bearings of the tail wheel must be made adjustable, each side independent of the other, and a range of 4 to 6 in. is usually found sufficient.

The distance between supporting pulleys or idlers is made about 32 ft., and the last one of these is kept not more than 10 ft. away from the driving wheel. These idler pulleys are made of cast iron, or preferably wood, and have a diameter of 16 to 20 in. The various belt pieces are riveted together with lap joints, using two rows of ⅛-in. rivets, 1¼ to 1½ in. apart; the end connections are usually lapped about 2½ in. The inside, or pulley side, of the belt is given a thorough coating of paint.

Usual Speed and Power Required

The usual speed of these belts is 164 ft. per min. or thereabout. They may, however, be run at a considerably higher velocity. The proper breadth of the belt is governed by the character of the material to be carried. For boards, logs and other materials of great bulk, one and one-half times the average width of the stream should be allowed for the belt. For coal, ore, etc., the breadth should be sufficient to allow carrying the material without having it come in contact with the sides of the guide channel or trough to any great extent.

The amount of power required for running these conveyers, of course, depends on the material transported, inclination of the conveyer, and to some extent on weather and other conditions. At one installation a belt 394 ft. long, center to center of turn wheels, and 16 in. wide, which is carrying 1766 cu.ft. of charcoal per hour at the rate of 164 ft. per min., requires, including gearing, about 3.6 electrical horsepower when running empty, and 5.1 h.p. when running full capacity. Of this amount 2.1 h.p. are consumed by the motor and gearing alone.

Another installation consisting of two 12-in. belts, 492 ft. center to center of turn wheels, running parallel, carries 3500 cu.ft. of charcoal per hour, at a velocity of 164 ft. per min., and when running empty requires 6.3 h.p., against 9 h.p. when running full capacity.

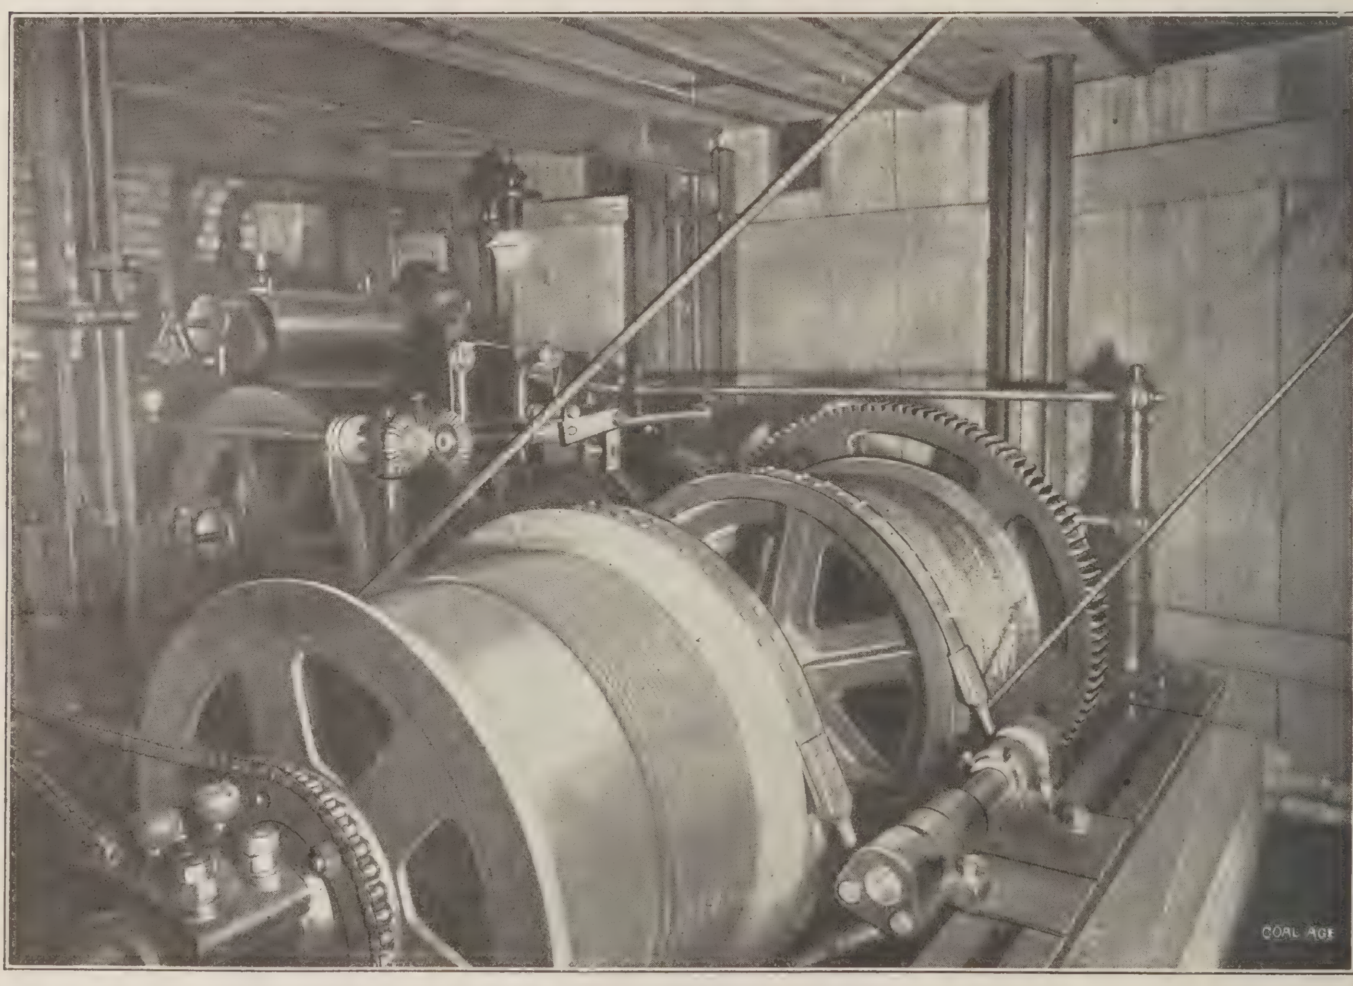
The best results are obtained from a shaker screen when the ratio of the length of the hanger to the travel of the eccentric is from 14 to 15 to 1.

Oil Engines in Coal Mines

Special Correspondence

European experience favors the use of oil motors, not only for haulage but also for general power purposes within the mines. No objectionable gases enter the mine air and the practice of using oil as a prime mover is on the increase.

At first sight it would appear that the underground working of a colliery is hardly the most appropriate place for an explosion engine, but, as a matter of fact, such engines have been adopted for locations of this description, and have proved in practice most useful and safe prime movers for the work which they have to do. In Europe, and particularly in Germany, the practical development of the gas and oil engine has proceeded with amazing rapidity in recent years, and there appears to be no end to the useful applications of these engines. Prominent among the firms who have participated in this progressive movement is the Gasomotorenfabrik Deutz, of Cologne, who are now building oil engines of both the stationary and the locomotive types for mine work.



UNDERGROUND HOIST DRIVEN BY OIL ENGINE, AMBERG, BAVARIA

Oil Motors for Mechanical Haulage

It is a well known fact that an appropriate mechanical motive power for the conveyance of small loads at moderate speeds has been wanted until recent years. This deficiency, which is especially troublesome in the working of mines, induced the firm mentioned to design a locomotive driven by an internal-combustion engine, as had been suggested by members of the mining industry. The trials made proved at the outset that the locomotive offered considerable advantages over other means of conveyance from an economical point of view, and the firm has already produced over 630 locomotives, aggregating 7000 h.p. As compared with steam motors, the advantages of the oil-driven locomotives are those of quick starting, attendance by one man only, no consumption of fuel when not running, no supervision of boilers, no risk of fire or explosion, no smoke nuisance, less dead weight to be carried than with steam locomotives, which require a large supply of coal and water, and, in combination with high efficiency, a small cost of upkeep, on account of economical consumption and the little attention needed.

Compared with the electric locomotive taking the current direct from overhead mains, the oil-driven locomotive secures independence of a central station; it is not subject to interruptions through absence of current; the first cost of the plant is considerably smaller, and there is no risk from contact with non-insulated overhead mains. Again, as compared with the electric locomotive driven by accumulators, time is not wasted in recharging, there is lighter weight, lower first cost, and less depreciation of important parts. For these reasons, the oil-engine locomotive has won for itself a definitely useful place in German mine practice.

The attention of mining engineers has, during the past year or two, been focussed largely on the relative merits of steam-driven and electric winders for collieries, but for capacities up to at least 20 h.p., the oil engine appears to have a good case. The illustration shows a 12-h.p. hoist driven by an oil engine at work underground, which was installed by the Royal Mining Administration of Germany, at Amberg, in Bavaria. The oil engine used is of the horizontal type in which an explosive mixture of liquid fuel and air is sucked through a conduit into the working cylinder on its suction stroke, the oil being introduced, intimately mixed with the air, in the form of a spray. At the end of the suction stroke, the valves are closed, the mixture is compressed on the return of the piston and ignited or expanded on the third or power stroke, the subsequent return motion scavenging the cylinder.

As the engine works on the Otto cycle, the cylinder is closed at one end only. Ignition is effected by means of a magneto. The drive from the engine to the winding drums or windless is effected through gearing, the engine and winder being mounted on an iron-frame bedplate, common to both.

Operations Consolidated by One Man

The spur-wheel transmission is seen in the figure, and note must be taken of the bevel gearing and rods and of a handwheel, which is fixed in the driving position, by the combined means of which the starting and reversing of the drums is effected through the medium of friction clutches. When these clutches are in their mid-position, both drums are free and at rest, the engine running light. A movement of the handwheel in either direction throws one or the other of the drums in gear. The brakes, which consist of a steel band passing around either drum as shown, are operated in this case, directly by foot pedal, although a handwheel and spindle may be utilized for the purpose. All the operations are under the control of one man, who need not move from his position either to attend to the engine or the winder. In some cases these gears have been fitted with the Koepe pulley, which is so often used in German mines.

It was at first conjectured that oil engines working underground would cause an offensive smell from the exhaust, but the waste gases in the Deutz machine are condensed so as to eliminate smell, and it is not found that any inconvenience is caused from this cause. For small underground haulages, either on the level or on gradients, these engines, from their self-contained character, appear to develop a new field of possibility which deserves careful attention, more especially as crude benzol or tar oil, petroleum, alcohol or gasolene can be utilized as fuel.

Coal Mine Inspectors and Their Appointment

In the various coal-mining States of America, it has frequently been urged, in the interest of safety and to make the inspectorate attractive to high-grade technical men, that the mine inspectors should be appointed in a manner similar to that used in Great Britain. In order that the question may be considered in its true bearing and from a point of view strictly uptodate, it may be appropriate to set forth the scheme of examination revised last month (September) by the Home Secretary with the advice of the Civil Service Commissioners.

The appointments are filled after a competitive examination, limited to candidates nominated by the Home Secretary. Applications for nomination should be accompanied by testimonials based upon personal knowledge of the candidate, indicating what experience he has had in mines, and giving information as to his character and fitness for the appointment. In their own interest candidates are particularly advised not to seek political or social influence, which will prejudice rather than assist their candidature.

In addition to the chief inspector and the electrical inspector, there are divisional inspectors (salary £750 to £1000); senior inspectors (£500 to £700); junior inspectors (£300 to £450). The divisional and senior inspectorships are filled by promotion, and vacancies for new appointments arise only in the ranks of the junior inspectors.

Every candidate must hold a first-class certificate under the Coal Mines Regulation Act, and must, within five years previous to his application, have been employed for two years as manager or under-manager of a coal mine or in some other responsible capacity, requiring regular attendance underground in a coal mine. Practical knowledge and experience of metalliferous mining and quarrying is also taken into consideration. Candidates must be between 23 and 35 years of age at the time of examination.

An inspector upon first appointment is subject to two years' probation. He must give his whole time to the official duties assigned to him. His tenure of office, increments of salary, promotion and pension, are dependent on good conduct and efficient service. Inspectors may be called upon to retire at 60 years of age, and retire in any case at 65.

Nature of the Examination

Already in possession of a first-class or colliery manager's certificate, the candidate is required to undergo examination in the following subjects:

English—Includes composition, the writing of reports and precise writing, but does not include indexing. Attention is paid to handwriting and spelling in this as in other subjects:

Elementary Mathematics—Will include arithmetic, algebra to quadratic equations, plane geometry, and plane trigonometry to the solution of triangles.

Elementary Geology—Outlines of physical geology, including the physical characters, chemical composition and description of rocks; elements of stratigraphy with special reference to the British isles; the construction and interpretation of geological maps and sections; the occurrence of coal, stone and metalliferous minerals. (In this subject there will be a laboratory test in addition to the written one.)

Coal Mining—Theoretical and practical; includes systems of sinking and working, methods of supporting roofs and sides, mechanical engineering as applied to coal mining, theory and practice of ventilation, surveying and making of plans, use of explosives, mine gases and their analysis, prevention of accident, rescue work, and the restoration of mines after explosions and fires. Mining hygiene.

Ore and Stone Mining—Theoretical and practical, including methods of sinking and working, methods of supporting excavations, mechanical engineering applied to ore and stone mining, ventilation of metalliferous mines, prevention of accidents. Ore dressing. Mining hygiene.

Electricity in Mines—Installation and use of electricity in mines, including the practical units of measurements and the use of simple measuring instruments; transmission and use of electricity by alternating and direct currents; the construction of cables and the jointing and testing of cables; earthing; the rules as to the use of electricity in mines and the prevention of accidents.

Law Relating to Mines and Quarries—Knowledge of the Coal Mines Regulation Acts, the Metalliferous Mines Regulation Acts, the Quarries Act, and the Rules and Orders made thereunder.

Oral Examination—Questions may be asked on coal mining, ore and stone mining and electricity.

Chemistry[1]—The principles of inorganic chemistry and the study of the occurrence, modes of preparation, and properties of the principal elements and their more important compounds. Questions may be given on the chemical principles involved in the commercial preparation of important inorganic substances. Elementary organic chemistry. (Also a laboratory test which will include the preparation and analysis of inorganic substances.)

Physics[1]—Will include heat, light, sound, electricity and theoretical and applied mechanics. (Also a laboratory test.)

[1]Chemistry and physics are optional: the applicant may take either one.

Anthracite and Bituminous Mining

By Eli T. Conner *

In the western-middle and southern anthracite coalfields, the inflow of surface water from extensive caving makes mining expensive. The coal of the southern field is friable and extensive briquetting may result. The third of a series of articles by Mr. Conner.

The Western-Middle anthracite-coal basin lies in Schuylkill, Columbia and Northumberland counties. It is 36 miles long, by four to five miles wide. For comparison with the deposits before described, there is incorporated a typical cross-section of this basin, from which it will be noted that the measures are distorted and the margins of the basin turned up so that the coal beds generally stand on steep pitches. This cross-section is taken from the second geological survey of Pennsylvania.

On account of the geological formation, the methods of attack, development and operation in this field are practically the same as in the Lehigh region, with such modifications as local variations have made necessary. Most of the older developments in this field were by slope on the coal bed from the outcrop, such as heretofore described, but on account of the cost of maintaining slopes in the Mammoth bed, there have been some notable departures from earlier developments by sinking shafts of large area and capacity at or near the center of the basin, and it is probable that future developments for the winning of the deeper lying coal must be by shaft.

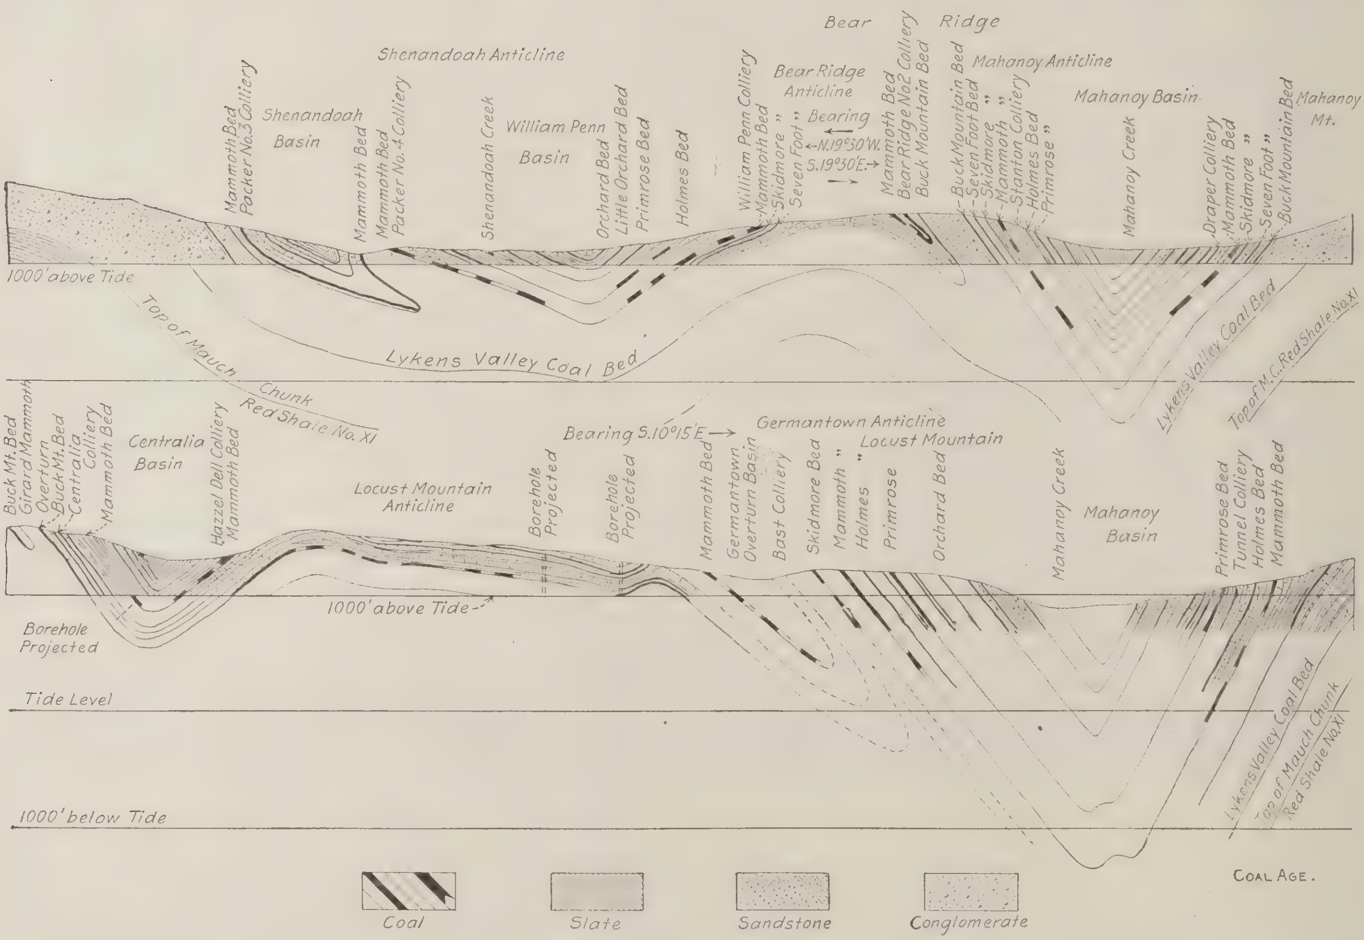
*Consulting engineer, Real Estate Trust building, Philadelphia, Penn.

The Mammoth Bed Is in Many Splits

In the easterly half of this basin, the Mammoth seam is similar to the same seam in the Lehigh region, but west of Mt. Carmel, this great bed of coal is found split into three and sometimes into four distinct and separated beds, which vary in thickness from 4 to 12 ft. This splitting of the seam, I believe, is a decided advantage, for if the workings are properly projected, and care is exercised to columnize pillars, in the several beds of coal, a better average yield from a given area is attainable than where the Mammoth seam is found all together, in one bed, 30 to 50 ft. thick.

The mining methods in this field being quite similar to those of the Lehigh region, they need not be further described, but I would like, in this connection, to call attention to the excellent paper by D. Bunting, on "Chamber Pillars in Deep Anthracite Mines," Bull. Am. Institute Min. Engrs., September, 1911; p. 739.

In this region, as in the Lehigh, the difficulties of operation and the consequent cost have been greatly enhanced by reason of the enormous crop fall, caused by the mining in the Mammoth seam, and by the running of chambers through to the surface at the outcrop. These tremendous surface openings admit large quantities of water to the mine workings, during the wet season, and necessitate the installation of large pumping plants. There have been many instances of the drowning out of collieries in which large amounts of money were invested.



Cross-section Western-Middle Anthracite Coal Basin

Large Influxes of Water during Floods

A notable experience of this character was in December, 1885, and January,

1886, when there was a long period of excessive rainfall, following a heavy snow. At that time I was superintendent of the Harleigh colliery, two miles north of Hazleton. On account of the terrific floods nearly every colliery in the Lehigh region was drowned out in the lower levels, and Big Black creek, which has its source near Eckley, flowing westward over the center of the coal basin, became such a raging torrent that its banks were overflowed on the Harleigh property, and the whole stream flowed into a crop hole leading from a chamber in the Mammoth bed. At that point, the center of the basin is overlaid by a considerable depth of marl and sand, so that in a remarkably short time the stream had cut a channel 20 or 25 ft. deep, at the edge of the crop hole.

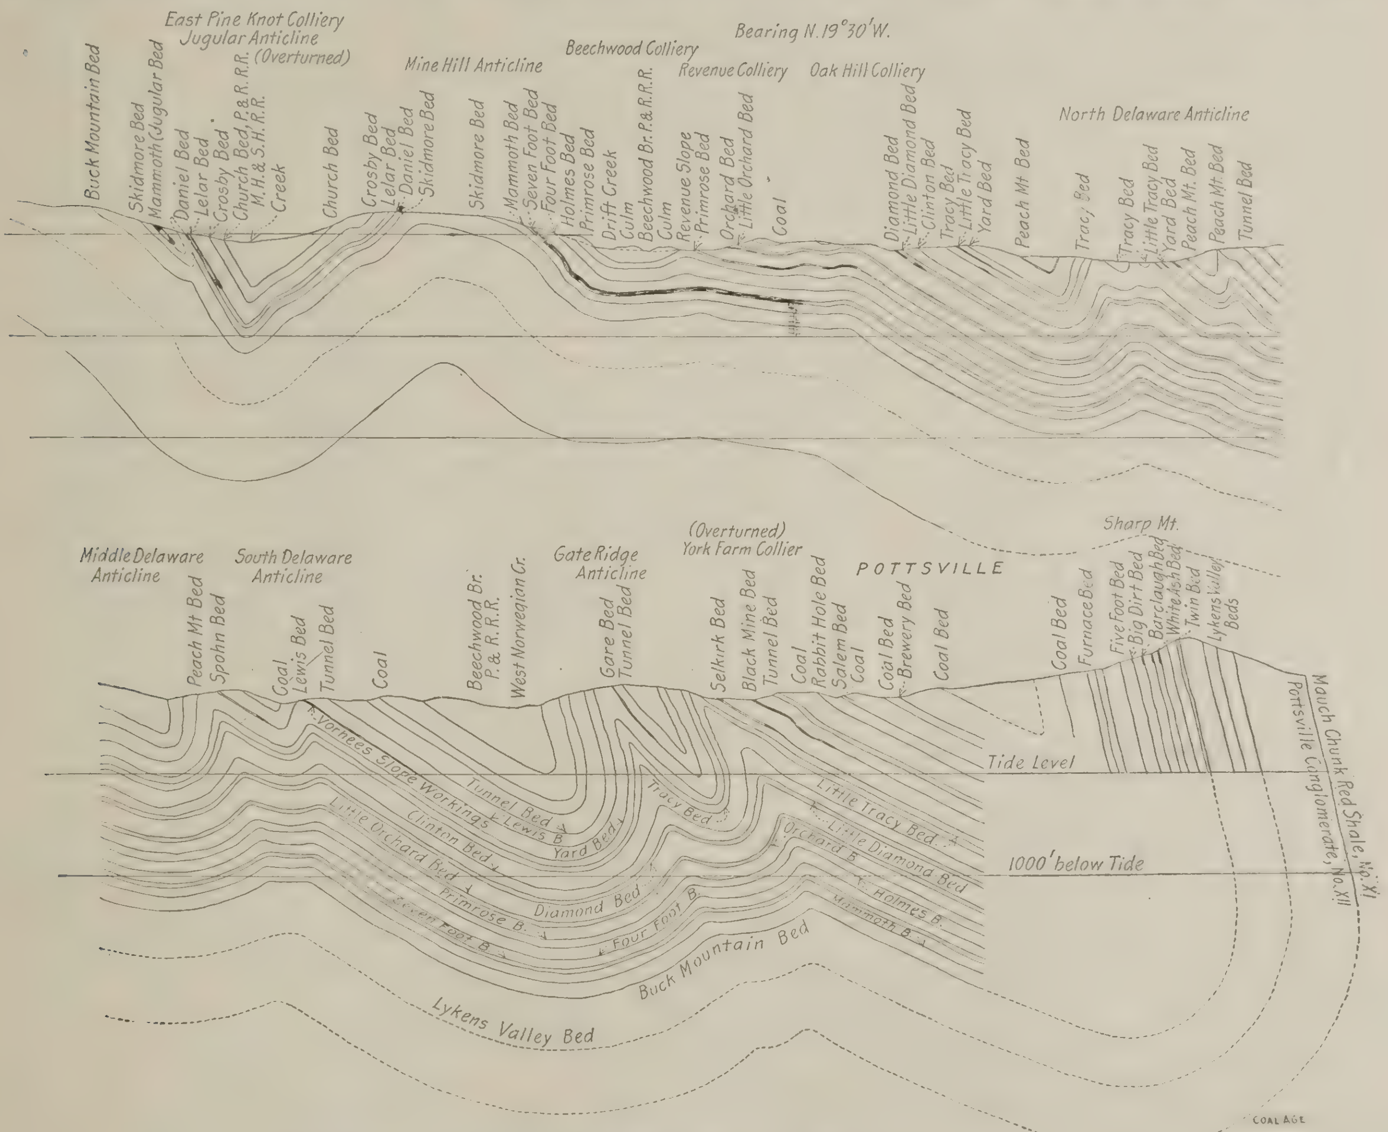
Strenuous efforts were made to direct the creek into a partially completed canal, constructed for the purpose of carrying this stream away from the coal basin, but before this was accomplished, the lower levels in Harleigh colliery and in Ebervale colliery, adjoining, which were connected by holes through the barrier pillar, were drowned. The continued rain in January caused a second break in the canal before mentioned, letting enough water into the mine to drown the pumps at both collieries. These two mines filled with water, and it was deemed impracticable to unwater them by ordinary methods.

The land owners and Messrs. G. B. Merkle & Co., operating the Jeddo collieries, who acquired possession of the property (Harleigh and Ebervale collieries), constructed from Conyngham valley a drainage tunnel about five miles in length, which tapped the workings in the Mammoth bed, near the basin on the Ebervale property. This tunnel has since furnished drainage outlet, not only for the two collieries originally drowned out, but also for the Jeddo collieries to the eastward.

Similar drainage projects have been completed at other points in these two coalfields, notably, at Beaver Meadow, by Coxe Bros. & Co.; at Centralia, by the Locust Mountain Coal and Iron Company and leasing landowners. Several others of lesser importance have been constructed. At the present time, a long and expensive drainage tunnel is in course of construction by the Lehigh Coal and Navigation Company, for drainage of its Panther Creek collieries.

Water Hoisting in Self-dumping Tanks

In the Western-Middle field, within recent years, several large shafts have been sunk by the Philadelphia & Reading Coal and Iron Company, the Lehigh Valley Coal Company, and mining companies under the control of the Pennsylvania railroad, for the sole purpose of handling water concentrated from several connected collieries. In these shafts, the water is hoisted in tanks by first-motion steam engines of large capacity located at the surface. This method of handling large volumes of water in the flood season presents advantages that strongly recommend it, under certain conditions, but detailed comparisons between the hoisting and pumping systems would be out of place here.



Cross-section of Southern Anthracite Coal Basin at Pottsville

(The lower section is a continuation of the upper)

It will be apparent from what has been said that the continued successful operation of collieries in these two fields means the investment of a large amount of capital, greatly in excess of what was necessary in the earlier days of the industry, when most of the operations in this field were developed by comparatively small companies and individual operators.

It is probably true that there are many collieries, which, considered purely as mining propositions, are unprofitable, and were it not for the freight profit accruing to the transportation companies controlling these collieries, they could not be continued in operation.

Elimination of Rock and Preparation of Coal

In the matter of preparation of the coal for market, after it has reached the surface; while the principles are the same in the southern field, as further north, the plant and equipment necessary differ materially. On account of the excessive pitch of the coal beds, most of the refuse in the seams of coal, together with roof rock that may fall, must be loaded into the mine car and brought outside. To handle this large quantity of rock, ample facilities must be provided at the head of the breaker. Recent new plants constructed by some of the large companies include a capacious head house provided with large platforms where preliminary separation of rock from coal can easily be accomplished, before sending the coal to the main breaker.

The Lehigh Coal and Navigation Company constructed a new breaker on these lines about two years ago, which has shown exceptionally good results and which is fully described in a paper prepared by the mechanical engineer of the company, Charles A. Straw, for publication in the transactions of the American Institute of Mining Engineers.

On account of the conditions described, and the manner in which the coal must be handled before it reaches the mine car, in these two fields, the average colliery produces much less prepared or domestic coal and a greater percentage of the low-priced steam sizes, than is produced in the Northern anthracite field, and consequently the average price realized for the total marketable product is lessened. In addition to this, by reason of what I have before said, there are many operations where from 40 to 50 per cent. of the raw product reaching the breaker is waste, either in the form of rock, slate, bone or culm.

It is obvious that it costs as much per ton to handle all this waste material as though it were a marketable product. All the cost of this refuse must naturally be charged against the going output. The conditions described largely account for the fact that the cost of production and consequently the operating profit in the Lehigh and Schuylkill regions cannot be as satisfactory as the average in the Northern anthracite field.

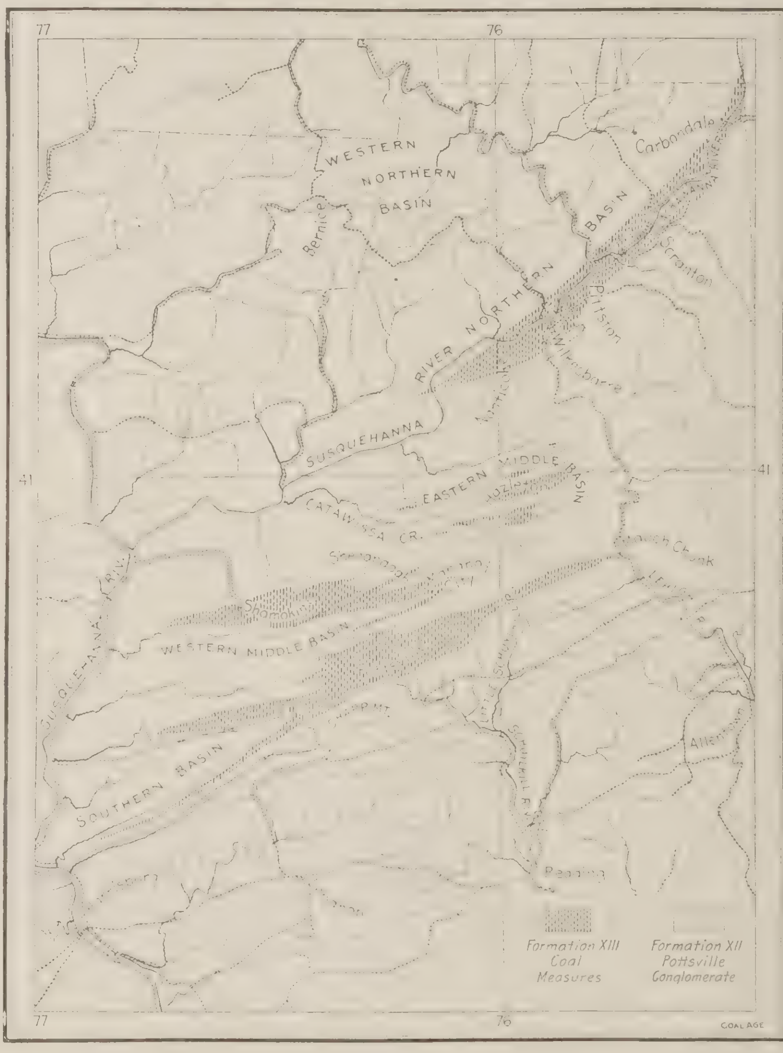
The Southern Anthracite Field

This is usually known as the Pottsville basin, and extends from Mauch Chunk, on the Lehigh river, nearly to Dauphin on the Susquehanna, a total length of about 70 miles, with a maximum width at the widest point of about seven miles. It consists of a number of connected basins, which increase in depth from north to south, culminating along the foot of Sharp mountain, in deep and greatly contorted measures, as will be noted from the cross-section herewith, which is taken from the second geological survey of the State of Pennsylvania. While this basin is usually termed the Schuylkill region, or Pottsville basin, the eastern end from Tamaqua to Mauch Chunk, controlled by the Lehigh Coal and Navigation Company, is generally classed as in the Lehigh region. The large number of coal beds underlying this basin and its great extent indicate an enormous quantity of untouched mineral. While it is true that there have been many developments made in this region, there is a larger reserve here relatively to its area, than in any other of the anthracite fields.

On account of the great distortion of the measures in this basin, it is frequently found that the coal is so crushed and soft as to produce in preparation an excessive amount of steam sizes, and culm waste, with a correspondingly small yield of prepared or domestic sizes. This is notably true at all of the collieries that have been developed under Sharp mountain. This condition has been the cause of the commercial failures of a large proportion of the operators who have made developments along the southerly side of the Pottsville basin, from Tamaqua westward.

The Eastern Part of Southern Field

East of Tamaqua, the character of the beds is somewhat better in regard to softness and friability of the coal. The same remarks, relative to the mine rock and refuse coming to the surface in the mine cars, apply in the major port of this field, as in the Western-Middle and the

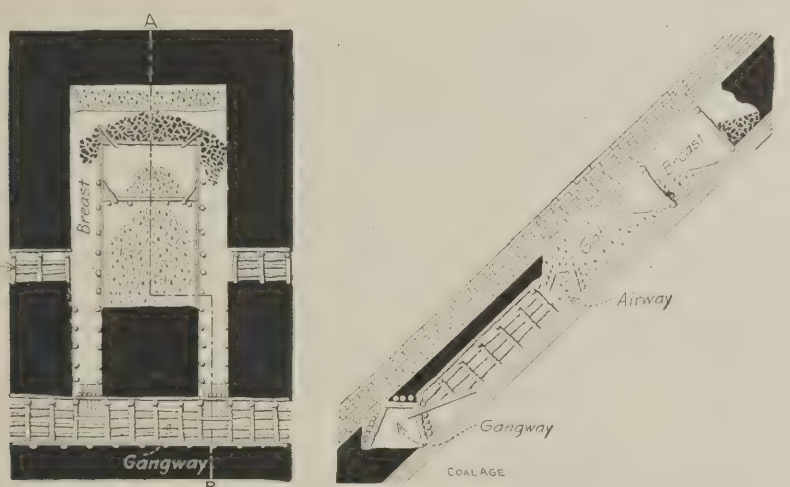


Map of Anthracite Coal Basins in Pennsylvania

Lehigh regions, but there is a larger percentage of culm in most instances, and consequently a lower yield of marketable sizes. Many operations in this field produce as low as 40 to 45 per cent. of domestic sizes, as compared with 55 and over in the two other fields and 65 and over in the Northern anthracite field.

It would appear then, that the only way to make profitable such operations as described, is either to secure a better average price for the output, or to find some means of converting the large amount of culm produced, into a marketable product.

To accomplish the latter, means must be found of burning dust in the form of a jet, which has been attempted by many people, but up to the present without marked success. Another solution will be found in briquetting the culm. This method has been perfected and two or three successful plants established, within recent years. The Lehigh Coal and Navigation Company has conducted extensive experiments, at Lansford, and recently completed a briquetting plant which is accomplishing good results. This plant is well described in an article by Charles Dorrance, Jr., which has been published by the American Institute of Mining Engineers.



METHOD OF WORKING PITCHING COAL WITH EXTRACTION OF REFUSE

BRIQUETTING COAL DUST IN ALBERTA

In connection with the subject of briquetting anthracite dust, I was privileged while professionally engaged by the Bankhead Mines, Ltd., of Bankhead, Alberta, to inspect thoroughly a briquetting plant which has been in service there for several years. This company has developed several beds of anthracite coal which, in geological condition, strongly resemble those found in the Pottsville basin. The coal is so soft that when prepared in a breaker, quite similar to those of the Pennsylvania anthracite regions, only about 22 per cent. can be recovered in sizes larger than chestnut, and only about 50 per cent. of the raw product of the mine will pass over a 3/32-in. round mesh, so that it will be seen that there is a large quantity of dust to be wasted. To utilize this material, and avoid the commercial failure of the proposition, a briquetting plant was installed, which, when I visited the operation, was producing about 500 tons per day, I was informed that some difficulty had been experienced in finding a market for the product, but these difficulties have been overcome, and all that can be produced is readily disposed of, at prices somewhat less than realized for prepared sizes of coal, but yet sufficient to make the briquetting plant a profitable operation, after paying to the mine $1 per ton for the dust, and bearing a cost of $1.75 per ton, of finished product, for the pitch used as a binder.

From these observations, I am convinced that such culm as is going to waste or being flushed into the mines in the anthracite fields of Pennsylvania, should be made into briquets now, or so deposited upon the surface, that it can in the future be utilized for this purpose. It would probably be impossible to find a market for all that could at present be produced, but as the culm banks deposited on the surface in the past are rapidly becoming exhausted, the market for briquets can, in all probability, be steadily developed.

SUBSTITUTION OF SAND FOR CULM

I think it is an economic mistake to flush culm into the mines where it cannot thereafter be recovered. The benefits of flushing for the recovery of pillar coal and the support of the overburden, should be secured by the use of other flushing material, as before mentioned.

In connection with the ultimate recovery of pillar coal, especially in basins where valuable improvements have been erected on the surface, and where it is found profitable to strip the outcrop of the coal beds, I think that instead of depositing the earth and rock at considerable expense on spoil banks, this material should be pulverized and flushed into the mine workings.

By this means, if properly deposited, the remaining pillars will be recoverable without serious rupture of the overlying strata, providing that as each pillar is extracted, the space from which it is removed is immediately filled with sand as has been customary with culm.

Water to Take the Place of Coal

INDIANA CORRESPONDENCE

A prediction that water power may come into extensive use in Indiana, to take the place of coal, is made by W. M. Tucker in the 35th annual report of the State geologist, which came from the printer recently. Mr. Tucker is engaged in a State survey of the water power derivable from rivers in the State of Indiana for the State Geologist Edward Barrett. He says that if fuels in Indiana and the country at large become exhausted as soon as it would appear from the rapidity with which they are disappearing, the lowlands along White river, the Wabash river and other streams will be condemned and used for storage basins from which water power will be developed for use throughout the State.

Mr. Tucker dilates on the problem of fuel supply in this and neighboring States, and shows how water power eventually may be necessary. He asserts that only about 10 per cent. of the water power of the State has been utilized by commerce.

ENORMOUS SAVING POSSIBLE

The State geologist asserts that if the State of Indiana could substitute steam-driven engines rated at 50,000 h.p. by water turbines of equal capacity, it would result in a saving of 500,000 tons of coal per year, in addition to a reduction of $12 for each horsepower saved by the substitution.

Water power is inexpensive and perpetual and requires less attention than any other power, when it is once installed. A proper development of the water power of Indiana would bring about several other important results. The navigation facilities would be greatly increased; the increased storage would tend to purify the streams and the reservation of water in the storage basins would tend to lessen the damage wrought by floods. The three problems—water power, navigation and protection from floods—are closely related. The great problem in each case is to bring about a regular stream flow. Immense reservoirs could be constructed in Indiana, and the water utilized for power, thus saving a large tonnage of coal each year.

Electrical Details at W. Va. Plant

By Henry D. Jackson*

> *The motor described was devised for driving a mine ventilating fan from a high voltage power circuit. Interesting features of the wiring installation at the plant of the McKell Coal Company are also described.*

Recent additions to the electrical equipment of the McKell Coal and Coke Company, Glen Jean, W. Va., are two new substations and an electrically driven fan. One of the substations, that at Tamroy, is similar in general construction and equipment to the previous installation.

At Kilsyth is an underground substation in the Kilsyth mine, about a mile and a quarter in on the main entry, and approximately 350 ft. underground. The high-tension lines to this substation are carried overhead to a shelter which is shown in Fig. 1. At this point a 6-in. hole was bored directly down into the airway just outside the substation. This bore hole was then fitted with an iron pipe approximately 3 in. in diameter, through which the cable was lowered. The interesting feature of this installation is the simple method employed for supporting the cable.

There were no means of supporting the cable in the pipe, and it was deemed necessary to arrange it so that it could be readily withdrawn at any time. The cable consists of a 10,000-volt, three-conductor No. 4 stranded wire, insulated with varnished cambric covered with lead 5/32 in. in thickness, and armored with No. 4 gage galvanized wire, the whole weighing 266 lb. per 100 ft. To support the cable, an iron ring made of metal 1 in. in diameter was slipped over the armor, the armor then bent over this ring, firmly wrapped about the cable and tied so as to form an annular branch near its end, and thus support the weight entirely by the armor.

The cable was then threaded through a hole in a steel plate 6x18x2 in. in dimensions, the hole being approximately 2½ in. in diameter, and large enough to allow the cable and the wrapping after it has gone around the ring, to fit snugly into it, so that the entire weight of the cable is carried by this steel plate, which in turn rests upon a concrete pier, as shown in Fig. 1. This enables the entire cable to be easily supported and readily removed.

At the top of this conductor, are installed the lightning arresters and choke coils to protect it and the machinery in the substation underneath. The method of bringing in the high-tension wires is more distinctly shown in Fig. 2, which is the layout for the wiring and the motor foundations at the fan, the second item of interest.

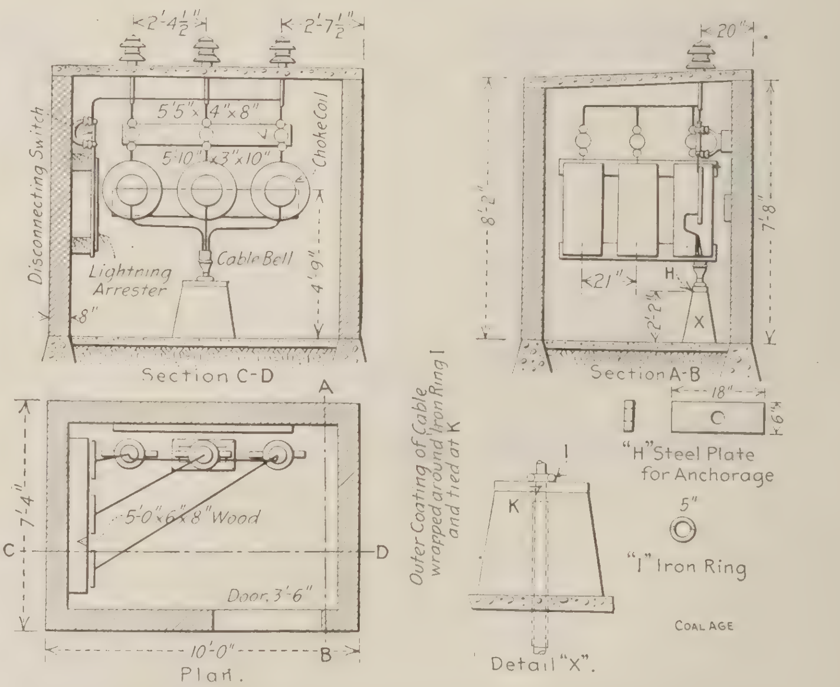


Fig. 1. Shelter over Bore Hole and Details of Support for Hanging Cable

The Fan Installation

The fan installation is of interest, because of the use of a special type of motor, and also possibly because of the use of a chain drive. When the question of the installation of this fan came up, it was carefully considered whether it would be advisable to use an induction motor of sufficient capacity to handle the fan during the early stages of the mine development, and increase the size of the motor as the development of the mine necessitated; or put in a motor which would be capable of handling the fan at its maximum capacity, varying the speed of the fan as conditions required, by means of changing pulleys.

The conditions at the plant were such that the power factor of the system as a whole was low, and it therefore seemed wise, if possible, to install a synchronous motor of a capacity equal to the capacity of the fan, utilizing the excess capacity of the motor during the early stages of the mine's development as a condenser, and thus raise the power factor of the entire system, improve the regulation and incidentally, a very important item however, obviate any necessity for installing an additional engine and generator in the main power plant, as the low power factor and the addition of the two new substations and the proposed fan would bring the current load on the generator considerably over its rating although the load on the engine was by no means up to its capacity.

The ordinary synchronous motor has a very slight starting torque, only sufficient to start itself without load, and owing to the generally severe operating conditions in coal mines where the employees are by no means well trained or careful, it was deemed unwise to use a clutch between motor and fan, as there would be always a possibility of wrecking the clutch or stopping the motor by too sudden application. This consideration, then, required a permanent connection between fan and motor, and made it imperative that the motor should be capable of starting the fan and bringing itself up to synchronous speed, thus requiring a type of motor which up to this time had not been successfully built.

It was quite possible to reduce the total load on the fan motor when starting, to approximately 75 per cent. of its full load power, by means of closing the inlet and outlet doors of the fan; but even this load was far beyond the capacity of any previously built self-starting synchronous motor. Further, the conditions of the installation were such that it was necessary to limit the starting

*Consulting engineer, 88 Broad street, Boston, Mass.

current on the motor to not over 2½ times normal current at full load. This in itself is a condition which is rarely attained in the best designed types of induction motors.

It required a great deal of correspondence, much urging and a number of interviews with the salesmen of the electrical manufacturers, to convince them that such a motor could be built, we feeling that there was no good reason why a combination motor could not be built which would have the characteristics of a high-resistance rotor induction motor, and a synchronous motor in one machine. The alternating-current side of the machine could be the same as for a synchronous motor, and the two windings, those of the induction motor and the field windings of a rotary field synchronous motor, placed upon the same shaft. Further, we felt that the marked poles of the synchronous motor field would act as anchor points, as it were, to hold the synchronous motor in synchronism at intervals during the rotation of the rotor, while acting as an induction motor.

A Unique Type of Machine

Two companies only would bid upon the work, these being the General Electric Company and the Westinghouse Company. The contract was awarded the Westinghouse Company, who built the motor shown in the illustrations, Figs. 3 and 4, it being a 250-h.p., 25-cycle, 6300-volt, 500-r.p.m. machine, provided with induction motor windings on the rotor, for starting.

The motor is started by means of two switches; the main-line switch when thrown upward connects the motor to half-voltage taps from the auto transformers; when the machine reaches full speed at this voltage, the second switch is opened, throwing an inductance in series with the machine. The first switch is then thrown down, sending the full line voltage on to the machine with the inductance in series, these inductances preventing a great rise in the current. When the motor reaches full speed under these conditions, the second switch is closed, short-circuiting the inductance, and leaving the machine on full voltage. The field rheostat is then adjusted to the excitation desired, and the machine automatically locks in step or synchronism.

During the test at the Westinghouse works, this motor pulled 95 per cent. of its full-load rating into synchronism, and the instantaneous current rise was less that 2½ times normal full load running current. It is to be noted that this test at the Westinghouse works was somewhat less severe than would be the condition under actual operation, as the test load was a direct-current generator, the current from which was carried through a fixed resistance, so that the load came on as the square of the speed. Under the conditions of operation, that of driving a fan, the load would come on as the cube of the speed.

The installation of this motor proved very satisfactory. The power factor was raised approximately 30 per cent., bringing the total load on the main plant considerably under the generator's rating and improving the operating conditions to a marked extent.

Owing to the limited space at the location of the fan, a belt drive was out of the question; and the idea of gears was eliminated on account of the noise, so that a chain drive was installed for the work. The final installation will require a chain 16 in. in width, and a speed of the fan of 210 r.p.m. The present installation uses a chain 4 in. in width and a fan speed of approximately 50 r.p.m., the power being approximately 30 kilowatts.

Under these conditions, if an induction motor had been used, the power factor of the system would have been approximately 55 per cent. At present, the power factor is between 85 and 90 per cent.

The success of this motor has led to the building of a large number of motors of similar character by both the Westinghouse and the General Electric companies for work of a similar nature. It is a type of motor exceedingly well adapted to coal-mining installations, inasmuch as it

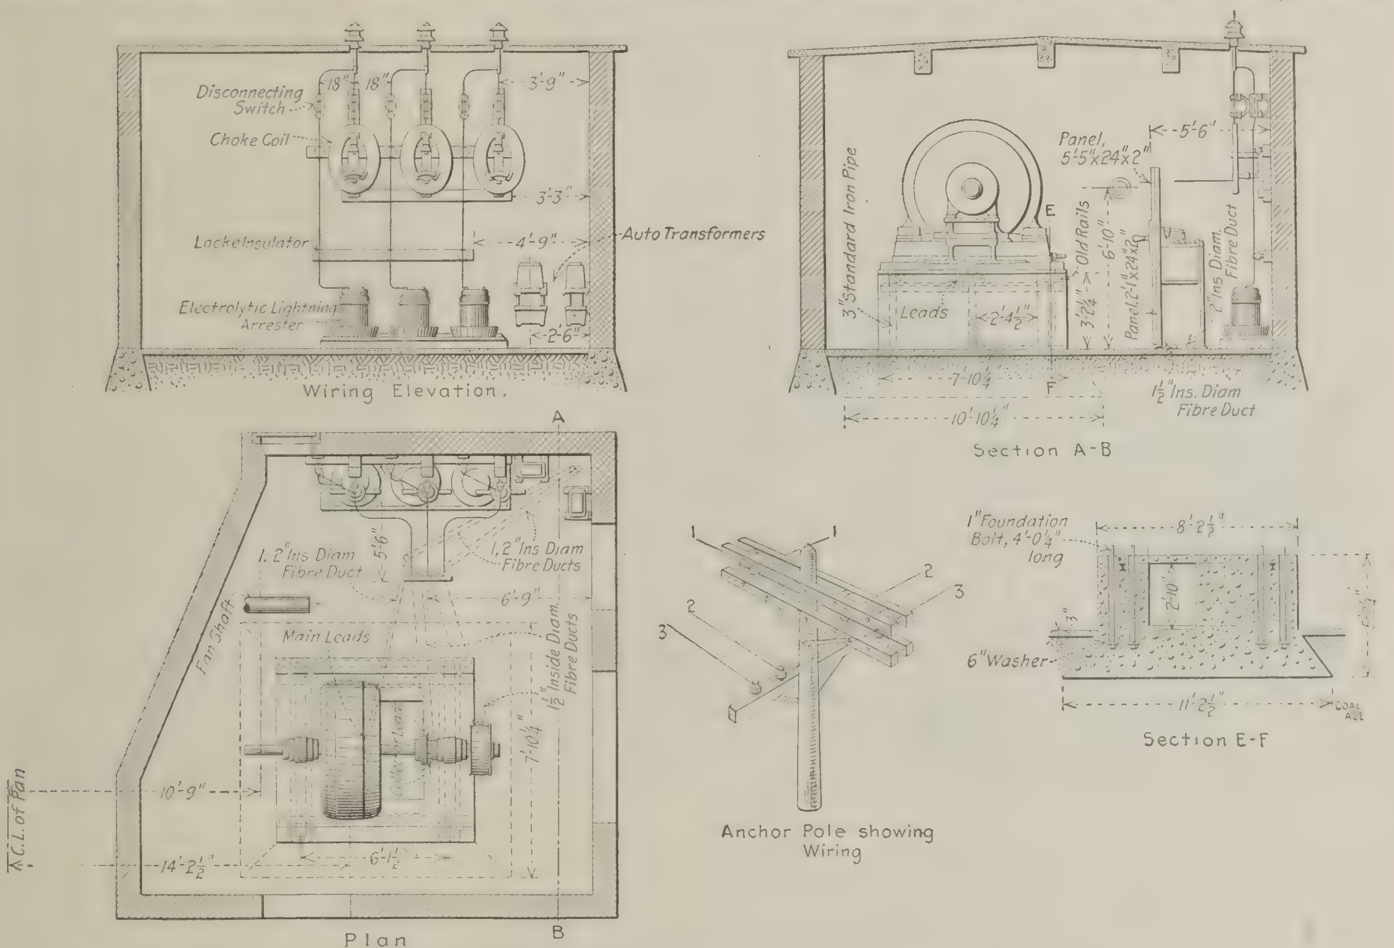

Fig. 2. Motor Room of Fan House, Showing Wiring Details

entirely obviates the necessity for clutches, and allows of the power factor on the alternating current circuit being kept high and the regulation of the system made good, a condition of affairs which cannot be accomplished where induction motors are used entirely, unless the motors are loaded to their full capacity.

It is well known that a motor of this type is likely to give more or less trouble in case of an accident to the prime mover or a short circuit on the line, owing to the fact that the inertia of the air in the mine and the inertia of the fan will keep the motor moving, and the motor, because of its exciter, will then act as a generator, turning back power into the line and supplying current to apparatus which the generator originally supplied before its circuit breaker opened. This sudden reversal from motor to generator may pull the motor off its foundation, unless means are taken to prevent such an occurrence. In the present installation this is accomplished by means of a reverse current relay, which, immediately upon reversal of the direction of current in the line, opens the switches and cuts the motor off the line.

Method of Bringing Wires into Motor House

It may be of interest to note the method of bringing in the high tension wires to this motor. This is shown quite distinctly in Fig. 2. The main wires are brought to a dead end at an anchor pole, and then are dropped to the insulators, which are cemented into the concrete roof of the fan house. These insulators are of the strain type, and therefore have a hole directly down through the center. The top of this hole is covered by means of a brass cap, which weighs approximately 3 lb. The wires are brought directly to this cap. A solid brass rod is screwed into the bottom of the cap and extends down through the hole in the insulator. This rod is fastened to a three-way connector, as shown in the drawing. In order to increase the sparking distance, this rod is covered by a porcelain tube, which extends well up into the hole in the insulator. This method of installation has proved very satisfactory, and allows the wires to be brought in without the necessity of open places, which would allow birds and insects to fly in and out of the substation and motor-house.

Exhaust Steam Turbines

The recovery of power from exhaust steam, by means of exhaust-steam turbines or mixed-pressure turbines is a subject which has come prominently forward during the past few years. The success which has attended the introduction of such turbines into various manufacturing and other industrial plants has led to their recent installation in connection with a group of English collieries.

Heretofore engineering effort in connection with extracting the energy from exhaust steam has been directed chiefly toward the use of condensers and feed-water heaters. The application of these to engines having rapidly fluctuating and intermittent loads has often been attended by marked difficulties, and as a result, the majority of colliery hoisting engines and large haulage engines are still exhausting into the air.

The scheme of the English installation referred to was based on an existent grouping of eight pit centers or mine openings within an area consistent with electrical distribution. At three of these centers were large hoisting engines having possibly 500 kw. in exhaust steam going to waste, and the conversion of this into electrical energy for distribution among members of the group, and thereby eliminating small isolated boiler plants, was the object sought.

It is claimed in this connection that even were the application of condensers to hoisting engines a comparatively easy and commercially safe matter, the turbine would still possess decided advantages as an extractor of power from exhaust steam.

Two Constituent Compounds in Coal

Recent experiments by M. J. Burgess and R. V. Wheeler, regarding the volatile constituents of coal, lead the experimenters to believe that coal can be separated mechanically into two distinct substances, and they hope to compare the results of destructive distillation of these substances, as regards both their liquid and gaseous products, with those produced by the action of heat on cellulose and its derivatives, because they feel justified in assuming that one type of compound in coal is a degradation product of cellulose.

Their experiments have already shown that two more or less distinct compounds exist in coal; one decomposes easily at a comparatively low temperature and yields the paraffin hydrocarbons; the other more stable compound is found to decompose rapidly at a temperature between 700 and 800 deg. C., and yields principally hydrogen, together, possibly, with oxides of carbon. The latter and more important compound they hope to identify as cellulose or one of its derivatives.

Hill Publishing Company

John A. Hill, Pres. and Treas. Rob't McKean, Sec'y.

505 Pearl St., New York.
6 Bouverie St., London, E. C.
Unter den Linden 71, Berlin.

Correspondence suitable for the columns of Coal Age solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 6000 copies. No copies will be sent free regularly. There will be no back numbers. The figures which will be shown here each week will represent live, net circulation.

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

COAL AGE

Fireproof Breakers

That anthracite breakers should be of fireproof construction if at all compatible with the expected life of the colliery, is a conclusion which has been definitely reached, to judge from the best of the recently completed and proposed new construction.

Over 20 years ago, Eckley B. Coxe built the Drifton breaker of cast and rolled metal throughout. In recent years the Reading, the Delaware, Lackawana & Western, the Erie and the Lehigh Valley companies have all erected breakers of fireproof or partially fireproof construction. The only valid objection is expense. Whether or not the additional cost is justified is a matter that must usually be worked out for each case on its individual merits; however, for new plants which have an expected life of 20 years or more, fireproof construction should be preferred.

Opinions differ considerably, however, as to whether steel, reinforced concrete, or a combination of concrete incasing steel members is the best medium for securing this result. Of structural steel it may be said that it is a well known quantity. Those familiar with its use can proportion a framework to its loading with an accuracy which practically eliminates that waste of material so often met with in heavy timber construction. It makes possible a light, strong frame which takes up a much smaller proportion of the housed-in space than either concrete or timber, and while not so elastic as timber, it is immensely more so than concrete.

On the other hand a steel frame has comparatively little mass, and unless given ample weight and a liberal supply of diagonal bracing, is liable to be seriously affected by vibrating machinery of the kind found in most breakers. In this connection, however, it may be remarked that much can yet be done toward reducing vibration by the proper balancing of the machinery. Some apprehension must also be had in regard to effectively protecting steel against the action of acid water. Certain special paints have given good results in this respect, but they must, of course, be frequently applied and the structure designed with this fact in view.

Reinforced concrete is a quantity not quite so well known as steel, and for a structure built along the lines of the usual wooden breaker, it is likely to prove exceedingly expensive. Some of the advantages of this type of construction are those which pertain to a rigid monolithic structure of sufficient mass to absorb the shock and vibration brought to it from the supported machinery, but unless so designed as to unquestionably secure this result, the outcome seems to have a rather dubious aspect.

Another advantage of concrete construction is its great durabiliy and consequent low cost for repairs. On this score, as with steel, apprehension need only be had regarding the effect of the acid water. Ordinary concrete is easily permeated and itself more or less disintegrated by such water, and the danger consequent upon acid attacking the inclosed steel is immensely increased by the fact that it cannot be kept under observation. There are on the market certain waterproofing compounds which may be able to give adequate protection in this respect at a price which is not prohibitive, and others are likely to develop, but so far the effectiveness of none has been finally demonstrated under the conditions which obtain in most breakers.

In regard to a steel framework protected by incasing with concrete, it may be said to offer an admirable and conservative, albeit expensive, type of construction, in which the known strength and reliability of steel is combined with the mass and durability of concrete. But unless the fact is indubitably established that the inclosing concrete will effectually protect the steel against the possible inroads of acid water, this type of construction should scarcely be considered for wet breakers.

On the whole these several types of fireproof construction all have their spe-

cial advantages, as has also that of heavy timber, the prevailing type at present in breaker construction. One thing obviously to be avoided in the design of new work is coming to an unalterable decision upon any one certain type of construction, and then merely for the sake of building something "all steel" or "all concrete," as the case may be, sticking to it even to the extent of using such construction in places for which it is absolutely or comparatively unsuited.

Concrete has its field in this work apparently close to the ground, where massive construction is easily possible and particularly desirable. Steel is admirably suited for the superstructure, and there are numerous places where nothing will do quite so well as a few sticks of timber or a plank flooring. In short it would seem that the desired end of a suitable breaker structure of fireproof character will best be attained by combining these various materials of construction in such way that each will constitute that part of the completed building to which it is peculiarly adapted.

Limitations of Shaft Output

The constant demand for greater outputs from shafts is met with a blunt *non-possumus*. While 4000 tons is frequently reached from easy slope- and drift-openings, such a tonnage is well-nigh impossible from a shaft. When a large output is desired, two or more hoisting shafts must be sunk and even then such tonnages as have been mentioned are difficult to obtain. The cars must be increased in size and two cars must be caged end for end. There are obvious objections to both these methods of circumventing the dilemma. Large cars demand large and high roadways and wide gage. Two cars set tandem, if not of equal weight, are said to put the cage so appreciably out of balance that it crowds the guides. Decking the cage involves stoppages which are undesirable in deep shafts and which render decking useless in shallow ones.

The tendency in mine haulage is toward the endless rope, traveling continuously in one direction. Slow speeds are possible with large tonnage where the haulage is not reciprocating because the outward flow of coal is not obstructed by the inward travel of empties.

But it is in shafts that reciprocation reaches its limit. Each car or pair of cars must be caged, the signal be given to raise, maximum speed be reached and almost immediately reduced. Then the cars must be landed and empty cars caged or else the cage must stop the length of time necessary for self-dumping, however short that may be. The reciprocation involves engines of great power acting only a small percentage of a full day and wasting much available energy in brake friction.

We may never see the abolishment of cages in shafts where coal is fragile and the market disposed to call for large lumps. But with the increasing sale for small sizes, there may well be a time when the demand may come to produce coal regardless of dimension. Even now small coal is preferred where it is produced for coking purposes, and in at least one field, the size of the fuel is not regarded as affecting its sale.

It is possible, then, that in a few years, we may see conveyer lines raising continuously up a shaft, buckets, skips, or even whole cars of coal, and dumping them automatically. It is easy to point out difficulties. There never was an innovation which did not involve them. But modern progress in conveying machinery will hardly fail at some time to solve these problems. There is still too much uncertainty in conveyer machines, especially in places where they are subject to corrosion from mine air, mine water and atmospheric moisture.

Furthermore, the weight of the coal to be kept in motion will be considerable and will furnish some difficulties. But the chief difficulty is to be found in the weight of the lengthy conveyer chains or ropes, yet even this is not insuperable. A German inventor by the name of Schwidtal in Silesia, has patented the interposition of sprocket-wheels in between the head and foot sprockets of a conveyer drive. These sprockets actuated by separate motors would serve to relieve the links and sprocket teeth from any weight except that of the chain, the buckets and bucket loads between one sprocket and the next below.

Coal Land Laws

No single detail of the coal-mining industry has received the national attention given the formation of adequate coal-land laws. The unfortunate Alaskan episode, together with Mr. Roosevelt's promulgation of an active conservation policy, has brought this topic home to all coal men generally.

The hue and cry is for laws favorable to the "poor prospector," and the exclusion of corporate interests. Few people appreciate the fact that in the West, as a rule, only the largest corporations are in the coal business—and these companies only because they are forced into it. The large railroads and metal-mining corporations are compelled to maintain their coal departments for the reason that there is not sufficient coal in the open market to meet their requirements. A cursory examination of a list of Western coal operators will show that only a small percentage of coal is mined by interests not connected either directly or indirectly with the large corporations. The obvious conclusion is that Western coal mines have not, as a rule, proved to be a profitable investment. To one familiar with the Cretaceous coals, also the geology and the topography of some of the Rocky Mountain States, this needs no explanation.

A law to be effective to the interests of the man of moderate means must be something on the order of the leasing system. To acquire a section of land at, say, $50 per acre (an average or even low price for land available to transportation facilities) requires an almost immediate expenditure of $32,000, not to mention the cost of prospecting and developing. Under these conditions the ordinary prospector must immediately enlist the aid of capital, thereby sacrificing a large share of his interest.

More Daylight

It is said that a sailor will build himself a house like a ship's cabin, but it would probably be considerably overshooting the mark to suggest that the coal-mining fraternity build their surface structures in simulation of conditions below-ground. Nevertheless, there are certainly some breakers, dark enough, dirty, damp and devious enough to give body to the idea, and nearly all colliery buildings suffer to some extent from the lack of light and space.

It is well to remember that daylight is usually about the cheapest thing that can be put into a building and has a wonderful earning power. Space, it is true, is likely to be expensive, but so is the necessity for having men climb, crawl, duck and dodge about their work instead of going easily, directly and confidently.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

English authorities are inclined to favor a stoppage of the fan after an explosion, so that poisonous gases are not spread through the mine.

Explosives should not be taken into the mine in a frozen condition as they are then very susceptible to shock and require extra care in handling.

A long exposure to humid conditions, it has been found, renders coal dust moist and inert, but the presence of moisture in the air at the moment of explosion is not sufficient to prevent an explosion; that is, not enough moisture is carried by the mine air to reduce materially the temperature of the flame.

It has been ascertained that fuses having a normal rate of burning of 27 sec. per ft. may, under the influence of pressure alone, burn as fast as 8 sec. per ft. On the other hand, conditions of temperature may cause it to burn as slowly as 70 sec. per ft. It is suggested that accidents may arise owing to the liability of explosives to exude nitroglycerin from cartridges.

The advantages of the endless-rope method of haulage are regularity of delivery and low speed. This latter need not exceed 2 to 2½ mi. per hour, which means fewer runaway cars and other accidents, reduced cost in wear and tear on the road bed, longer life of the rope (four times that in main and tail haulages), and not so much power required because the empties can be run in by gravity.

Pine and red or black oak commonly used in mines, each have their own destructive fungi. *Fomes .annosus* .attacks pines and *Polystiaus versicolor* is confined to the oaks. The germs may enter the timber before or after cutting, but usually decay is contracted in the mines from nearby decayed timbering; hence the importance of removing timber as soon as it shows signs of decay.

When it is desired to secure an approximate idea of the movement or velocity of an air current that appears almost stagnant, and if an anemometer is unavailable for immediate use, a heavy rag, or a piece of brattice cloth charged with dust will prove a ready means of making the test. A rap of the hand on the rag or cloth will raise a cloud of dust which the air current will carry away, allowing the observer to form an estimate of the velocity.

The fumes from colliery waste banks may constitute a danger to the crops of surrounding farms and fields. For instance, the fumes from a waste bank, in Yorkshire, were blown on to a field of turnips. The effect of the fumes was to cause sulphuric acid to settle on the ground, kill the bacteria in the soil and stop the growth of the crops. The crop of turnips was short by ten tons and the farmer sued the colliery company, which was fined and made to pay costs.

At the Whitburn colliery, in Durham county, the mine ponies are fed with a mixture of 35 per cent. chopped hay, 29 per cent. crushed oats, 27 per cent. crushed maize and 9 per cent. crushed beans. At the week end they have occasional bran mashes. Each stableboss looks after an average of 15 ponies, and each pony is provided with a separate set of harness. During the week, a stableboss is on duty in the stables during practically the whole of the 24 hours.

The only absolute cure for what is known as the "clinkering" of a poor coal is said to be low-temperature combustion. This clinkering is due to the presence of calcium, iron and sulphur. It has not been definitely ascertained in what proportion these elements may be present without causing clinkering, but Brost's formula is generally applied, namely, the fusion temperature rises as the alumina increases, and falls with the increase of the other elements, but it cannot be relied upon for any particular ash.

The native miner in India is usually accompanied by his wife, who conveys the coal from the working place to the main road where the cars are kept. The man cuts the coal and the woman carries it out in a basket on her head. The Hindoo will not work in a mine where he cannot stand straight up with a basket on his head. Some of the seams in the Iharia district are 30 ft. thick, and in the average working day a man and his wife will fill two cars. The rate of pay is from 10 to 12c. per car, and a man can keep his wife and family on about one-third of his earnings.

Nystagmus is a disease common among miners. It is claimed that it is much increased with the increased use of safety lamps. The miners put this forward as an argument against the use of the safety lamps, maintaining that these should never be used while it is possible to so thoroughly ventilate the mines that naked lamps can be employed without danger of explosions. This indicates one of the difficulties which have to be contended with in introducing safety appliances in the mines. In some cases, English miners are paid from 2 to 4c. a ton more when they use safety lamps.

Speaking from a practical point of view, R. R. Smith considers that its excessive speed is an objection to the turbine pump in collieries, especially in the event of a breakdown occurring. Makers claim that a turbine pump cannot break down, but motors can, and it is very necessary to be in a position to put on another motor quickly. Motors, however, are not often made for the higher speeds of from 1500 to 2000 r.p.m., and he, therefore, considers that gearing or a belt drive should be arranged so as to allow of a low-speed motor being used.

A memorandum of the Manchester Steam Users' Association explains that dense smoke indicates either that a boiler is overworked, that the draft is insufficient, or that the stoking is badly done. Light smoke indicates efficient stoking. With poor draft the fires should be kept thin and level by firing frequently and at one side of the grate at a time. If necessary, keep the air grids in the fire doors slightly open just after coaling, but a continuous admission of much air is wasteful; it spoils the draft and merely dilutes the smoke. When low water is discovered, cool the furnace plates from both sides as quickly as possible.

The average life of a pony underground varies a good deal. At the Harton collieries, in Durham county, it is slightly over six years, but in many cases the actual working life is very considerably more. The general manager of these collieries says that ponies under four years old are not sent underground. Recently three ponies were drawn out of these pits, which had been at work below ground for 15, 17 and 22 years, respectively. The one which had been at work 22 years was still fit and fresh and had both his eyes, but he was getting a bit stiff. To the foregoing we may add that in July at the New Hawne colliery, Worcestershire, a pit pony died which had worked in coal mines for 40 years, during 12 of which it never saw daylight.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Working Coal in Dips

In a certain butt heading there is a continuous dip from the top of the hill at *A* to the bottom of a small basin at *B*. The dip to the basin is so steep and the measures are so saturated with water, that from the top of the hill to the center line of the basin, the rooms when started would have to be widened to the left. The roof is very weak. How should the coal be worked so as to provide for adequate drainage for the rooms and for the safety of the men in drawing pillars? It is assumed that the ordinary room-and-pillar system has been adopted up to the point marked *A*.

MINE FOREMAN.

It is assumed that, as the roof is weak, a break can be secured anywhere so that it is not necessary to carry on the break obtained in the first rooms of the heading. It is permissible, therefore, to lay plans to obtain a new break in rooms near the dip. The rooms should be marked off, on the heading rib from the last already turned to the end of the heading. The first of these rooms so marked off should be set at the regulation distance, plus the standard widening of a room, added to 10 ft., so as to permit of a reversal in the widening of that room and an increase of pillar width in order that a skip may be taken off one side of it. All the other rooms down to the dip should be regularly spaced, but in the bottom of the basin the width between two of the rooms should be reduced by the amount of widening of one room.

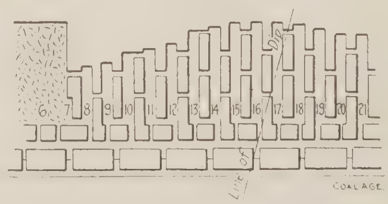
The rooms should be started first at the bottom of the dip and in due order other rooms should be opened to the left and right of the same. Those to the left of the dip should be widened to the left; those to the right should be widened in like manner to the right. It is assumed that the roof in the first section has already broken down. When the last room in the dip section on the left, marked for recognition as Room 8, is driven half way up, a track should be laid through a crosscut to the next room (Room 7), and a skip taken off the side of that room all the way up to the face.

The accompanying illustration shows the status of the working, when the skip is just commenced.

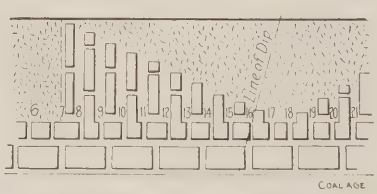
The pillars of the rooms at the bottom of the dip should be first attacked, following with those to the right and left. The order of progress in starting and drawing the room pillars should be a continuous recession from the center of the dip. The room made out of the skip off Room 7 should be drawn back when its turn comes. The figure following illustrates the manner in which the pillar drawing should proceed.

This method of work only satisfies mining conditions where the roof is weak. If the rooms up to and including No. 7 had not caved well, the skip could not be taken with any safety, for it would be involved in the ultimate fall of the first seven rooms. If, again, a large area was being upheld, because fracture did not occur, it would be wrong to attempt to try to create another fracture at Room 7, because the pillars between rooms 7, 8 and 9 would probably be lost, if more were not involved. As a general rule, where the roof is good, it is not well to arrange to use such strategy that pillars have to be drawn between two falls. Moreover, where the roof is sound and gives plenty of warning of its caving, some variance from accepted method can be safely permitted. It is customary in strong roofs to drive rooms 40 to 50 ft. wide, with a road on each side. The miner, who is removing the coal on the side nearest the fall, whether that fall be actual or anticipated, is situated in what would be considered a very perilous position, were the roof weak. On the other hand, if the roof be weak, especially if it be also broken, the system set forth in the illustrations would necessarily be used to safeguard the miner.

BEFORE ROOMS ARE DRIVEN



DRIVING OF ROOMS AND SKIP



PILLAR DRAWING

Size of Shaft and Fan Required

We have a 1500-acre tract of coal land underlaid with a 5-ft. seam of bituminous coal, gaseous and lying flat. If a capacity of 2000 tons per day is desired, what should be the size of a double-compartment shaft, and what size of fan would be required to furnish the air for this mine, in accordance with the Pennsylvania bituminous-mine law?

PENNSYLVANIA OPERATOR.

This is a large daily output to obtain from a shaft with one car to a cage and working only 10 hours per day. Practically, the size of the hoistways is determined by the necessary dimensions of the mine cars, which again are determined by the required output per hour, the speed of hoisting, and the conditions in the mine with respect to the thickness of the seam or the available headroom and width of mine roads.

In the absence of actual data, it may be assumed here that the coal (5 ft. thick) is overlaid with an 18-in. drawslate, which is allowed to fall, a few feet behind the face. The total hight in the passageways and rooms is then $5 \times 12 + 18 = 78$ in. Using 18-in. car wheels and allowing 12 in. for ballast, ties and road; 3-in. car axles, and 13½ in. for crossbars, clearance and creep, gives $78 - (12 + 9 + 1\frac{1}{2} + 13\frac{1}{2}) = 42$ in. for allowable depth of coal in car, including topping.

Assume the track gage is 4 ft. Calculate the cross-section of the mine car as follows: $g = 4$ ft., $d = 18$ in. Then: Lower section, $42 \times 9 = 378$ sq.in.; middle section, $\frac{56 + 42}{2} \times 7 = 343$ sq.in.; upper section, $56\,[42 - (7 + 9)] = 1456$ sq.in. Total sectional area $= 2177$ sq.in. $= 15.12$ square feet.

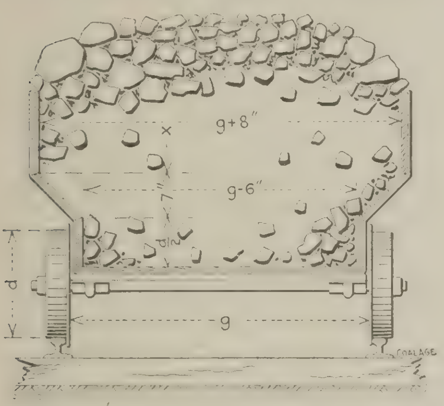
To find the length of the car it is necessary, first, to find the weight of material per hoist and the cubic contents of the car; thus, assume, for this depth of shaft, that the maximum speed of hoisting is 40 ft. per sec., and allow 30 sec. for starting and stopping each trip and dumping car. The time of hoisting one trip is $\frac{400}{40} + 30 = 40$ sec. Now, allow 30 min. for unavoidable delays each day of 10 hours, making the actual time of hoisting coal

$10 \times 60 - 30 = 570$ min. The total number of hoists per day is then $\frac{570 \times 60}{40} = 855$ hoists. The weight of material per hoist is then $2000 \div 855 = 2.34$ tons, or $2.34 \times 2000 = 4680$ lb. Average bituminous coal (run-of-mine) may be estimated as occupying 40 cu.ft. per short ton (2000 lb.) The cubic capacity of a mine car, including topping of coal, must be, then, $4680 \div 40 = 117$ cu.ft. To have this capacity the inside length of the car must be, in this case,

$$\frac{117 \times 144}{2177} = 7.74 \text{ ft., or } 7 \text{ ft. } 9 \text{ in.}$$

Allowing, say 21 in. for end-boards and bumpers and 18 in. for clearance at the two ends, the necessary width of the shaft should be 11 ft. The inside width of the car is 4 ft. 8 in., and allowing 2 in. for side of car, 4 in. clearance, 4 in. for exposure of guides, 8-in. buntons, and a pumpway and manway 6 ft. wide, makes the length of the shaft 20 ft. in the clear. The size of the shaft is, therefore, 11x20 ft. inside dimensions.

It is only right to add that as miners in the bituminous parts of Pennsylvania work only eight hours, with considerable deductions at both ends of the day, coal being relatively scarce in the early morning and late at night, it is not well to look for a production of 2000 tons from a single shaft with a one-car cage, even if the hoisting should continue 10 hours.



Capacity of Mine Car

On many days the delays will much exceed an aggregate of 30 min.; also holidays, their approach and their aftermath, cut a wide swath on the exact results of mathematical calculation, for even if men are plentiful, the absence of a few will disturb the balance arranged between headings and diminish tonnage. The problem, however, excludes a larger car than that proposed and does not seem to warrant a five-compartment shaft with two hoisting engines, nor a double-deck cage carrying two cars on one deck. It would seem better to meet a problem involving only 1500 acres of 5-ft. coal by preparing an equipment which might produce 2000 tons, but which might fail to reach that tonnage by a few hundred tons.

In regard to ventilation, the revised bituminous mine law of Pennsylvania requires the circulation of 200 cu.ft. of air per min. for each person employed in a gaseous mine. The records of the past nine years show that the average daily output of coal per man employed underground is as follows:

Pittsburg Coal Company	3.7 tons
H. C. Frick Company	6.2 tons
Monongahela River Consolidated Coal and Coke Company	4.2 tons
Berwind-White Coal Mining Company	3.5 tons
Average	4.4 tons

Taking this average as a basis of calculation, the number of men employed below ground in a mine putting out 2000 tons of coal a day would be $2000 \div 4.4 = 454$ men. It would, therefore, be amply sufficient, as far as the mine law is concerned, to estimate on air for, say 500 persons, or a circulation of $500 \times 200 = 100{,}000$ cu.ft. per min. However, the practical needs of this mine, which is gaseous, may require, in emergency, more than double this quantity of air; and the normal working of the mine may even require more air than the law demands.

Estimating Size of Fan

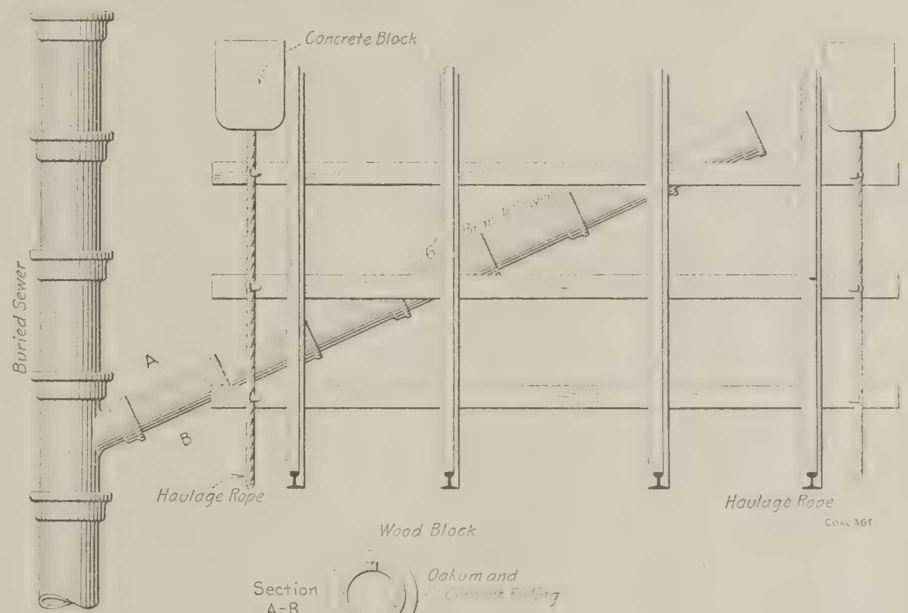
For this reason, in estimating the size of fan required for the proper and safe ventilation of the mine under all conditions, it should be designed to pass, say 150,000 cu.ft. of air per min. against a 2-in. water gage, at a moderate speed of, say 100 r.p.m., requiring for this service an indicated horsepower of the engine of, say 80 h.p. This would be the normal working condition. The engine driving the fan, however, should be capable of increasing the speed to 190 r.p.m., at which speed the fan would deliver about 250,000 cu.ft. of air, and, for the same mine conditions, the water gage would be increased to about 5.5 in. This would require about 360 i.h.p. The fan for this service should be 15 ft. 10 in. diameter, 5 ft. 7 in. wide, with a central opening 8 ft. 11 in. diameter. This makes the radial depth of blade 3 ft. 5½ inches.

Anchoring Gravity Planes

I have much trouble with a steep gravity plane which is always washing out; I cannot keep the ties in place. Please recommend a cheap remedy.

Roadman.

Your best plan is to lay a line of tile on one side of the track with properly cemented joints. All the water you can divert from the head of the plane should be passed down this drain. Several wyes should be put in the line and 6-in. branches run from these under the track. These branches should be cemented on the under half. The upper half should be left uncemented so as to drain the roadbed. Cover the ditches in which the branch pipes are laid, with broken stone.



Draining a Gravity Plane and Securing It By Haulage Ropes

Some planes are laid with anchored wood-sills into which the cross-ties are notched. The notching results in speedy rotting of the timber and the expense of such a method is considerable. The use of long ties common to both tracks is to be recommended, but perhaps the best security and the cheapest is the use of a spiked haulage rope at the end of ties secured to a heavy timber, masonry or concrete support at the head of the plane. If the plane is long, two or three of these may be necessary so as to divide up the expansion from heat. Old, disused ropes will do, and a heavy coat of tar will prevent them from rusting away, this coat being applied before and after their attachment to the ties.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Electric Lamps in Mine Rescue Work

The use of portable electric lamps in mines is rapidly becoming general. In gaseous mines. the portable electric lamp has been used effectively in so many instances to replace the ordinary so called safety lamp as to call properly for its classification as a safety lamp.

In the meaning of the anthracite mine law an electric lamp is not a safety lamp. Indeed, the law needs revision in this respect. When the present law was passed there were only two general types of safety lamps in use, the Davy lamp and the Clanny lamp. These laws, however, are now obsolete in respect to many present methods of mining anthracite coal, and we can but hope that the new law when drafted will provide effectively and intelligently for these changed conditions of mining, and treat specifically the new methods and new devices introduced since the old law was made.

Not long ago the government rescue car visited our coalfield, and trained men in the use of electric lamps in gassy mines, in connection with rescue apparatus. In the strict meaning of the mine law the electric lamp is not a safety lamp. I firmly believe in the electric lamp as the lamp that can be most effectively used in mine-rescue work; because where this lamp is carefully used the chances of ignition of gas are reduced to a minimum, and because the lamp gives a good light, which is very necessary.

A short time ago there occurred a heavy cave, in a mine, along the gangway road, in a steep-pitching (80 deg.) seam. An entire pillar of coal came down on the gangway, as shown in the accompanying sketch. Two men were working in the face of the gangway at the time of the cave, and their escape by that road was completely cut off. The ventilation was also cut off by the cave, and gas began to accumulate rapidly in the workings beyond. Soon a fireboss with an ordinary safety lamp reached the point marked *X* on the airway, but could go no farther. At this point, the gas was so thick that it extinguished the light. There was no way to reach the entombed men except through the airway or monkey heading above the gangway. Two ladders were brought in and placed in the manner shown in the sketch. Two men, each provided with rescue apparatus and electric lamps, traversed the fall by means of the ladders, and reached the entombed men in the gangway. These men were found in a very weak condition, at the point marked *X X*. The two rescue men were unable to take them out, so one rescuer returned for help while the other stayed with the men. The man who went out brought in another rescue man and two sets of rescue apparatus, which they put on the unfortunate men. The three rescuers then took the men out, one at a time, thereby saving these two men who were almost at the point of death. They would have perished had the electric lamps not been used.

This incident illustrates one case where the electric lamp was used effectively in saving life, under conditions that rendered the ordinary safety lamp useless. The question may be asked here, however, if anything had happened to the rescue party or the men through the use of these lamps, would those responsible for their use in a gaseous mine have been held accountable to the mine law?

Should not the electric lamp be classed in the mine law as a safety lamp? The true aim of the law is to protect lives and property, but when a law becomes obsolete it is then a menace rather than a safeguard, and should be changed to meet the changing conditions.

A RESCUE FOREMAN.

[EDITOR'S NOTE—The term safety lamp is a misnomer, and too often misunderstood by miners; particularly by those who are unacquainted with the use of the safety lamp. This misunderstanding may and often does lead to serious accident, because the one using the lamp has the idea that it is *safe* under all conditions, and cannot pass flame or cause trouble.

This is a grave error. The so called safety lamp is safe only when properly used by one who understands the principle of the lamp and the properties of mine gases, as well as the dangers to which he exposes himself and others by a careless use of the lamp. As a matter of fact, no lamp, however well protected, is safe under every condition of mining, and therefore, care and intelligence are necessary on the part of the person using the lamp.

Our correspondent has drawn attention to a very important point and one that is growing in importance every day. Portable electric lamps are rapidly coming into general use in the mines. We think the day is not far off when they will entirely displace the lamps and torches now in use. Mining law should take cognizance of this fact and special reference should be made to the use of such lamps. The electric lamp has the same right to classification as a safety lamp, as the present types of so-called safeties now in use.

The determining feature of the safety lamp is the more or less complete isolation of the flame of the lamp from the surrounding atmosphere. In the incandescent lamp the carbon filament of the lamp is more completely isolated from the outside atmosphere than is the flame of any oil-burning safety lamp. The glass globe of the incandescent lamp needs to be protected, but is not so apt to be broken as the glass cylinder of the mine safety lamp is liable to be cracked and broken by the heat of the flame and gas burning within the lamp.

The disadvantage, thus far, of all electric lamps, for mining use, is the fact that, as constructed at present, they do not reveal the presence of gas. It is to be hoped, however, that even this difficulty may be overcome and that some device will soon be found that will supply this lack.]

Siphon vs. Gravity Drainage

The accompanying sketch shows a mine in skeleton, with the elevations of the rail and ditch above tide. When the mine was first opened, there was much water at *A*, which was handled by a small hand pump, but later this water drained through crevices in the limestone measure below and no more trouble was experienced till the workings in the headings beyond *B* and *C* were reached. The further developments gave so much water that a sump was established in a low-lying room, as shown, and the water was removed by a siphon, much dissatisfaction resulting from its irregular service. It might be noted that the drawing is more of a diagram than an actual plan. This was necessary to avoid making too large a drawing. The obvious criticisms that it would be better to shoot the dip and to disregard the accumulation of water to the right of the drift mouth would not be obvious nor even applicable to the actual mine.

The following method was suggested for improving the drainage system:

By drawing a dotted line on the map, representing all the area in the mine above the elevation of the highest point of the drainage ditch, we obtained the area which could be drained if we constructed another ditch in the mine fol-

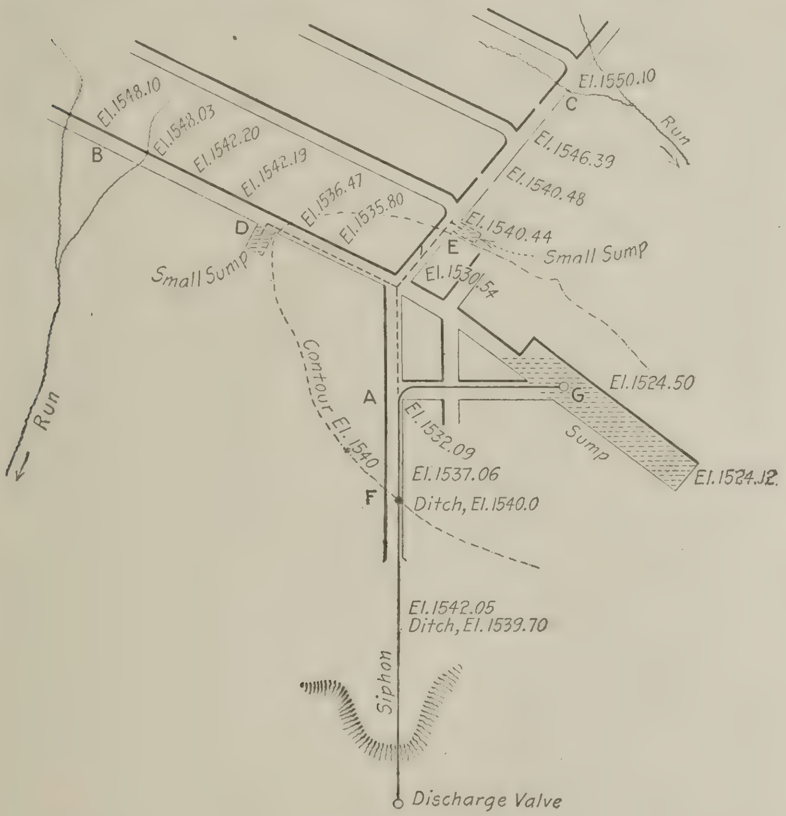
lowing that line, with ditches leading leading thereto. It was apparent in the early development work that all water originating below that line would pass away through the creviced substrata. What originated above the dotted line could, for the most part, be led to the several adjacent headings and run down to points *D* and *E* and piped from those points to the surface, by stringing pipes from *D* and *E* to the siphon line at *A* and connecting thereto. This suggestion was followed. The flow of water then depended not so much on the vacuum at the summit *F* as on the pressure of the water in the pipe, driving it forward and eventually upward to its own level. The custom of leading all water immediately stored at *D* and *E*, in order that it would not be necessary to drain the upper part of the mine continuously.

Preparations were made for using the old siphon, priming it with the water in the higher part of the mine. A valve *H* was put in the water line just above *A*, where the siphon line and the high-level branch join. A valve was located at the point of discharge *I*. By closing the valve *I* and removing the plug at *F*, all the air could be driven out at that high point. When the plug *F* was replaced and the valve *H* closed in the order named and the valve *I* opened, then as both legs of the siphon were fully primed, the siphon began working and continued to pass the water through the line till the

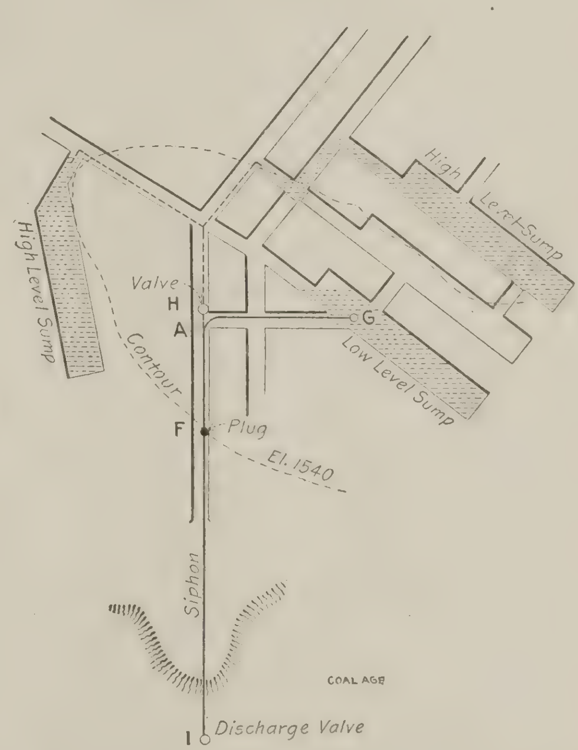
For 12 months inquiries and investigations have been in progress to determine the best sites for the shafts and, in July, Mr. Edden obtained permission to introduce a bill giving legislative authority to acquire lands and establish mines.

The scheme is to have a mine in the north, one in the west and another in the south, one of the proposed shafts to be in the neighborhood of Lithgow. When successfully launched these three mines will supply all the requirements of the government railways, street railways, brickworks, steam vessels, etc. Any surplus coal will be sold to private consumers.

At present the railway department has contracts with 24 collieries from which it



SYSTEM OF DRAINAGE WITHOUT USE OF SIPHON



SYSTEM OF DRAINAGE BY BOTH GRAVITY AND SIPHON

to a common sump situated at the lowest point in a mine and thence laboriously lifting it out is a common and deplorable source of waste of energy. A check valve was placed at *G* to avoid the discharge of water into the original sump. The water was accelerated in the pipe by occasionally opening the plug in what was once the high spot in the siphon, viz., *F*. When the flow of water was reasonally continuous, no air accumulated at that point.

Later, the crevices in the floor proved insufficient to drain the area below the contour line 1540, partly because of leakage from higher levels, the drainage of which could not be controlled after the pillars were drawn. Provision was then made so that water could be temporarily

low-level sump was empty. As soon as that occurred the valve *H* was reopened and the drainage of the upper area continued as before, for the check valve *G* prevented any water running down to the low-level sump. The siphon, being rapidly and efficiently primed under that system, gave better satisfaction and had less water to handle than it did before.

Chicago, Ill. A. O. BURT.

Government Coal Mines

COAL AGE readers may be interested in a plan of the Minister for Mines in New South Wales. He has in hand a project by which the government there will supply all its own coal requirements from its own collieries.

obtains approximately 840,000 tons of coal per anum. The Minister of Mines estimates that by owning its own collieries the state will effect a saving of half a dollar on each ton of coal, or roughly $420,000 on the total yearly supply.

The idea of state-owned coal mines is not a new one. New Zealand and Victoria own mines with, it is claimed, satisfactory financial results. It may also be recalled that in Germany, France, Russia and Belgium the various governments have their own mines for railway purposes, and in the United States and Canada certain large private companies have found it a paying proposition to own and run their own coal mines.

Liquor Problem in Mining Communities

By C. L. Fay*

One of the curses of the mining town is the "beer wagon." A superintendent of one of the large anthracite companies said recently: "It would be a forward step if we could stop the sale of intoxicating drinks which are hauled in by teams and peddled through our 'Patches.' It is against the law and if it could be stopped, I believe good would result. If the men had to order liquor or go after it, they would not use nearly as much as when it is hauled to their doors. In the 'Patches' where the beer wagons do not visit there is the least trouble, and the men do not lose so much time from work." Quoting further: "At one of our collieries, I never saw a beer wagon enter and I have never had complaints from there regarding quarreling or fighting; at one of our other mines, they are never without drink and the people are always in a 'scrap' about something—one lawsuit after another—there the women drink almost as much as the men."

Another official of the same company says: "Some time ago I went with the paymaster on payday and saw the beer wagons standing on the public roads selling beer at 5c. per bottle, or six bottles for 25c. I am told they do not do this now, but that they sell it by the case right from the wagon, which also is a violation of the law."

The "speak-easy" reveals the fact of the need of law enforcement.

In one county, officials in a position to speak with authority, say that there are as many illegal selling places in the county as there are licensed saloons.

In the last issue we saw the outcome: Here we have an illustration of an interpretation of law preventing an industry from minimizing the drink evil and here also we have a lack of enforcement of law, which permits the increase of liquor consumption to the detriment of an industry which is the support of the community.

While both the interpretation of the law and lack of law enforcement may act as obstacles to dealing with the liquor problem on the economic basis, there are also local conditions that add to the difficulties.

*Secretary, Coal Mining Institute of America, Wilkes-Barre, Penn.

Note—This is the third article discussing the above subject.

Brewery Stock for Moral Support

A mine superintendent, in discussing this phase of the problem, said that the brewing company in his district offered him a block of stock in the brewery syndicate at 50 per cent. less than par value. He did not accept the proposition and the stock was then offered to him at 25 per cent. of par value. Again he refused the offer. The agent of the brewery then told him that he (the superintendent) was a "key man" in that district, and that the brewery syndicate desired his good will, and that they would make him a present of the block of stock. The superintendent again refused to accept the offer. One of the chief officials of that brewing syndicate told me that the same year they paid a dividend of 66 per cent. on every dollar's worth of stock.

Surely a tempting investment for a mine superintendent or foreman. But when officials of coal companies hold stock in a liquor syndicate and that stock pays large dividends, effective measures to reduce the sale of liquor in the communities they control will be out of the question, even though the coal company may lose in tonnage every month.

But the industries are asking, "How shall we deal with the problem?" and that is significant. In the meantime, before a satisfactory answer is given, several large operating companies are projecting various plans in an effort to mitigate the demoralizing conditions.

One of the largest holding companies in West Virginia has written into all leases to operating companies the following article: "The lessee shall not sell or knowingly permit the sale or introduction of any intoxicating liquors upon the above described tracts or parcels of land or any lands adjacent thereto."

In a letter dated Sept. 28, 1911, the general manager of one of the largest railroads in this country says: "In our book of rules and regulations governing employees, we have the following rule with reference to the use of intoxicants, etc. 'The use of intoxicants by employees while on duty is prohibited. The habitual consumption or the frequenting of places where intoxicants are sold is sufficient cause for dismissal.' It is the duty of our division officials to see that this rule is enforced.

"Our superintendents, trainmasters, master mechanics, road foremen of engines and other officials, whose duties require them to be on the road a considerable part of their time, are in a position to observe whether or not the employees are violating the rule, and when they discover a case of this kind it is the usual practice to caution the offenders and give them good advice; then if they persist in violating the rules, the penalty is enforced by dismissing them from the service.

"While, of course, with the large number of men employed on a railroad it is impossible to get at every case, we believe we are fortunate on our road in keeping the infraction of this rule down to the minimum, as the number of men dismissed for intoxication, is a small per cent. of the total."

A Law Unto Themselves

As society progresses, the leaders of any period may discover the conditions that ought to be maintained in society and industry. Such leaders are a law unto themselves—and by making conquest and planting their flag on the advance line, they gradually draw other leaders to that line, then the law is brought up to the same mark and the law brings up the mass.

When society and industry demand another forward step, leaders blaze the way till finally a new advance line is established. Again the law is gradually brought to that line, causing the masses to struggle toward that new advance line and thus the wheels of progress go round and round, but what a "sprag" in the wheels is nonenforcement of the law!

Enforcement of law reveals its strength or weakness, whether good or bad, whether or not it is equal to the needs of the times and the demands of the present advance line of progress.

In the succeeding article on the "Liquor Problem in Coal-Mining Communities," I will describe what is, perhaps, the best method in operation at this time for minimizing the drink evil in mining camps.

First Aid Movement in Hard Coal Region

During the past six weeks the First Aid Corps of the mines which have organized these helpful institutions have been holding contests throughout the anthracite regions, and remarkably interesting and instructive these have been. The contests have now become annual events in most mining localities in northeastern Pennsylvania. The men who are engaged in these contests take a personal

pride in the efficiency of the corps to which they belong.

During the time that these contests have taken place, exhibitions have been given in various centers, generally in the vicinity of Scranton, Wilkes-Barre, Pottsville, Shamokin, Mahanoy City, Carbondale and occasionally in the neighborhood of mining settlements. The contests are not competitions in the conventional sense. Although medals are sometimes distributed among the winners of a contest, the men are for the most part indifferent to the honor conferred by these, and to their intrinsic value. Indeed they seem almost to deprecate their institution as awards.

About two hundred corps have taken part in these contests during the time that they have been in progress. It is no exaggeration to say that first aid to the injured, scientifically administered, is now as much a part of the machinery of the anthracite mines as any other department of the executive administration of the colliery. Each mine with a first-aid corps has its dispensary at the foot of the shaft, fully supplied with such appliances as are immediately needed in any ordinary emergency.

While distributing medals at one of these contests recently an old clergyman declared, with considerable truth, in the presence of the men and officials of the two collieries between which the contest was held, that within his own recollection, some 35 or 40 years ago, the lives of the mules in the anthracite mines were much more carefully guarded than those of the miners, it being accepted as a managerial axiom that the loss of a mule was estimated at $3 a day for the period of its working life, while the life of a miner was of no economic value, no material difference in the profit and loss account of the working of the mine resulting by his accidental death.

Marriage

By F. A. Boag

The conditions of the gold-mining camps of the West are being duplicated in the coal camps of the country, near and far. The unrestrained wildness of the erstwhile inhabitants of the gold diggings was due mainly to abnormal earnings, the lack of home restraint and the absence of the matrimonial curb. True! the earnings of the miners do not appear extravagantly large to Americans, though they are larger than is commonly supposed. But to peasants from Central Europe they seem so bounteous that to spend the balance after their frugal appetites for food are appeased, demands frequent carousals. The new environment acts as new wine in exciting their spirits. But more obvious than all is the effect of the lack of family ties.

The same adventurous spirits of a like people went to the Dakotas and to Colorado. But the Oregon adventurers were quiet homemakers, were married and peaceable. The Colorado men, on the other hand, prided themselves on their wildness and wooliness. They had, no less than their neighbors, the qualities of good citizenship, but the rewards being high and the restraints weak, a wild period intervened between settlement and steady development. The governors and mayors of the West have not been unmindful of the strife-assuaging virtues of marriage and have from time to time sought to restore the uneven balance of male and female by assisted or encouraged immigration of the latter. Moreover, today, a trip west to the region of the Rockies of an Eastern maid almost invariably spells matrimony, usually under the most favorable auspices.

Two Ways to Meet Problem

There is but little question but what marriage would make a healthy improvement in the foreign population of our mining villages. The difficulty is to find a way to increase it. The immigration authorities, dreading the already too great advance of the white-slave traffic, would not favor any activity toward increasing the immigration of females even if the law permitted it. There are two ways by which the difficulty might be met: The operator can always discriminate in favor of married men, and Congress, which is always discussing the restriction of immigration, might provide for the exclusion of unmarried foreigners who did not meet certain other important requirements, leaving the bars a litle lower for married men.

Occasionally we read of a lifelong romance. An Italian peasant girl comes to America to marry an acquaintance of boyhood days, on money furnished by her future husband. Such accounts furnish good headlines, but, as a matter of fact, the Italian laborer unable to find a countrywoman in his new home, and too undesirable to be able to cross the race line for a wife, recalls an unmated girl acquaintance of earlier days and sends for her. Without thought of love, she recalls the fact that there is a living for her in America, a chance to escape an enforced diet of *polenta*, with hard stone-picking and burden-carrying in the fields, and joyfully she comes over to meet her *promessi sposi!*

Brawls, the Outcome of Celibacy

One does not wonder that an American-born Italian woman is in many cases a chattel for profitable sale and barter, so many are the would-be husbands, so few the would-be brides. Nor can we wonder at the fights and jealousies engendered when five kegs of beer and one woman are together in a house where there are as many as 14 boarders; for though statistics prove that the Southern European is more chaste than the American or Briton, his lust for revenge and the temptations of liquors to which he is unaccustomed, more than overbalance his other moral qualities.

It sometimes appears to me that more urgent than a reduction of white slavery, is the need for a suppression of white lawlessness in the mining centers. It is a need, moreover, deeply felt that, more and more, Europeans who come here should be naturalized and stay, leaving their wages here, not sending them abroad. Furthermore, we desire to be saved from the trouble of nationalizing continually new influxes of strangers who come, develop a little and leave, to be replaced by others equally needful of the action of the American "melting pot," to quote Israel Zangwill. Marriage is the hobble that will effectually hold such men. Without marriage, life is essentially incomplete and the lack of it always makes man a wanderer.

Mine Safety Demonstration

The National Mine Safety Demonstration takes place Monday and Tuesday, October 30 and 31, at Pittsburg, Penn., the board of managers comprising H. M. Wilson, representing the Bureau of Mines; Dr. M. J. Shields, the American National Red Cross Society; S. A. Taylor, the coal operators of the United States; Francis Feehan, the United Mine Workers of America; John Laing, the State mine inspectors; and Thomas B. Dilts, the industrial department of the Y. M. C. A.

On October 30 a meeting, commencing with an address of welcome by Director J. A. Holmes, at 9 a.m., will be held at the arsenal grounds. Following the address the visitors will be shown the various buildings and the nature of the work being conducted in them.

For the afternoon an inspection is arranged, at the Bruceton mine, followed by an explosion in the same with a further inspection later.

The Tuesday meet is to be held at the Forbes field, beginning with ten first-aid problems open for solution to teams from all over the United States. Then will follow tests in a dust gallery, where similar experiments will be made to those made at the arsenal on the previous day, but with coal dust present and with gas entirely absent. A demonstration of the action of afterdamp on birds will be a feature of this meet.

The prizes for first-aid work will be presented by President Taft and addresses given by John K. Tener, governor of Pennsylvania, Walter L. Fisher, Secretary of the Interior, of whose department the Bureau of Mines is a part, and Miss Mabel Boardman, of the American Red Cross Society.

A parade of 19,927 miners, each of whom represents one of the 19,927 men killed in the coal mines of the United States in the last twenty years, will impress on the spectators the terrible toll of life taken by the coal industry.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Suggested Questions

Strike, Dip and Pitch

Ques.—Explain the meaning of the terms *strike, dip* and *pitch*, as they relate to coal seams or "veins."

Ans.—These terms all describe certain lines or directions in inclined seams. For example: The *strike* of an inclined seam may refer to any level line in the seam, or it may refer to the direction of such a line. The strike line, or the line of strike, is always a level line, and may have any position in the seam. The outcrop of an inclined seam on a level surface is a line of strike. The term *dip* relates to the inclination of the seam. Any line drawn in the seam at right angles to the strike is a line of "full dip" or "full pitch" according as it is drawn to the rise or to the dip of the seam. The terms *full pitch* and *full dip* of the seam describe the same lines drawn in opposite directions. Any line in a seam drawn in a direction oblique to the strike or to the full dip of the seam has a dip or a pitch less than that of the seam. By the dip or pitch of a seam is meant its *full* dip or full pitch.

Direction of Slant Road

Ques.—In what direction must a slant road be driven in a seam having an inclination of 5 deg. in order that the road shall have a grade of 3 per cent.? The direction of the full dip of the seam is S 34 deg. 30 min. E.

Ans.—In an inclined seam the ratio of the tangent of the grade angle of a road driven across the pitch, to the tangent of the angle of full dip of the seam, is equal to the cosine of the angle the road makes with the line of pitch. Calling this angle *a*, in this case,

$$Cos.\, a = \frac{0.03}{tan.\ 5\ deg.} = \frac{0.03}{0.08749} = 0.3428;$$

and a = 69 deg. 57 min. Therefore, the angle between the road and the full pitch of the seam is 69 deg. 57 min. But the direction of the full pitch of the seam is N 34 deg. 30 min. W, and since the required slant road may be driven either to the right or the left of the full pitch, its direction may be either N 35 deg. 27 min. E, or S 75 deg. 33 min. W.

Ventilation in Anthracite Mines

Ques.—How is ventilation produced in mines in the anthracite region?

Ans.—In the anthracite mines of Pennsylvania, ventilation is most commonly produced by mechanical means. The larger mines are mostly equipped with different types of centrifugal fans. Many mines are still operating the old style of 14-ft., open-running fan; and some disk fans are in use. The modern type of mine ventilator, however, now being generally installed, is the large centrifugal fan inclosed in a spiral casing, and having its blades curved to conform to the conditions at the mine. This type of mine fan when designed to run normally at a fairly moderate speed of, say 150 r.p.m., gives the best service and the highest efficiency. In case of need the speed of the fan can then be increased at will to supply a larger volume of air.

Mine Ventilators Compared

Ques.—What are the comparative merits of the several appliances for producing ventilation in the collieries of the anthracite coalfield? Give reason.

Ans.—The mine ventilator that is designed to meet as far as possible all the conditions that are liable to arise in the operation of the mine is the ventilator having the greatest merit. Owing to the widely varying conditions in mines, no absolute rule can be given. There is, however, a growing preference among mine operators for the large centrifugal type of fan, designed to run normally at a speed that can be increased or decreased as the requirements of the mine may demand. Such a ventilator possesses a greater margin of service than the small, high-speed types of fan, which are better adapted to the work of blowing air against a considerable water gage.

The open-running type of fan, still in use at some mines, is very inefficient, because it discharges the air at a high velocity all around the circumference of the fan, which means a great loss of energy. Closed fans having a tight-fitting casing are also inefficient, because the air is only discharged from a small portion of the fan-wheel at one time. The spiral casing, on the other hand, permits the discharge of air almost completely around the circumference.

The disk fan is not an efficient type of mine fan, except for the ventilation of small mines. It is a convenient form of ventilator, however, when it can be used, for the reason that it admits of reversing the air-current in the mine, simply by reversing the engine driving the fan. The necessity for reversing the air in a mine frequently arises.

Blowing versus Exhaust Fan

Ques.—Give your opinion as to the advantage, if any, of a forcing fan over an exhaust fan working under the same conditions.

Ans.—Both of these types of fan are equally advantageous under the particular conditions to which each is adapted. The blowing or forcing fan is adapted to the ventilation of a non-gaseous mine where the main-return airways can be made the haulage roads. In a gaseous mine, however, haulage must generally be performed on the intake airways to avoid the danger of the ignition of gas by the lamps of the drivers. In this case, in order to avoid the use of doors on the main haulage roads, at or near the shaft bottom, it is necessary to adopt the exhaust system of ventilation and use an exhaust fan.

This much is offered in explanation of the proper use of the exhaust fan. For the same conditions, however, the forcing fan is the more efficient ventilator, because it is operating on the cooler outside air and under the mine water gage or pressure, while the exhaust fan is operating on the generally warmer mine air and under atmospheric pressure only. The forcing fan, therefore, by virtue of its position in the air-current is always operating on denser air than the exhaust fan, which gives it a higher efficiency under like conditions in the mine or airway.

In the mine, the forcing or blowing system of ventilation possesses a greater advantage over the exhaust system, because the gases generated in the old abandoned workings of the mine are forced out, in this system of ventilation, through any crevices or openings extending to the surface. They are not drawn into the mine as they are necessarily in the exhaust system. If there is a breakdown, however, and the fan must be stopped suddenly when the men are in the mine, there is greater danger of the outflow into the mine airways, of the gases accumulated in the old workings, in the blowing system than in the exhaust system of ventilation.

Opening a Colliery

Ques.—It is proposed to open a colliery on the following workable seams: Buck Mountain, 10 ft. thick; Skidmore, 8 ft. thick; and Mammoth, 25 ft. thick, pitching respectively 30 deg., 35 deg. and 38 deg. On which seam would you sink your slope; where would you place your

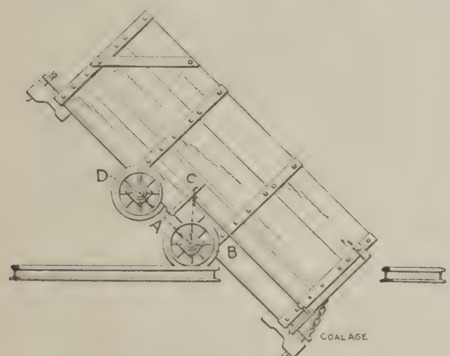
fan; and what kind of a fan, in your opinion, would give the best results, a forcing or an exhaust fan?

Ans.—Assuming that the conditions on the surface, at the outcropping of these seams, are equally favorable for locating the plant and for the loading and shipping of the coal, it would be generally preferable to drive the main-haulage slope in the thickest of these seams; namely, the Mammoth seam. This will give a good roof of solid coal while providing all the headroom desired in the slope. It would also afford easy access to the largest supply of coal. The other seams would be reached by driving cross-tunnels from the Mammoth seam, at the different levels. An exhaust fan should be located at the mouth of an airway driven in the middle or Skidmore seam. This main-return airway should be large enough to ventilate both the Buck Mountain and the Mammoth seams.

Balance Point of Tilted Car

Ques.—If the tilting of a car through an angle of 40 deg. puts it into balance on the front wheels so that no force need be applied to hold it in place, how far is the center of gravity located above the plane of the axles when the wheel base measures 2 feet.

Ans.—The accompanying figure shows a car tilted on the rails 40 deg. and the point marked *C* shown thereon is the arbitrarily chosen position



Balancing of Tilted Car

that is to be found. A line is drawn joining the centers of the two axles *B* and *D* and then from *C* a vertical is dropped to intersect *B D* in *A*. Join *C B*.

While the car stood on both wheels on a level track, *C A* was perpendicular to that track. Now *C B* is perpendicular to it or else the vertical line through the center of gravity must pass to the right or the left of the center of support (which is, of course, the axle of the car and the wheel tread beneath it). If it pass to the left, the car will fall back on the track, for there will be a gravity moment to replace it. If it pass to the right the car will fall forward, for there will be a gravity moment to upset it. But the terms of the question declare that at 40 deg. uptilt the car balances. Hence *C B* must be perpendicular to the track when *C* is rightly located. As the car has tilted 40 deg., *A C*, the original vertical, must form an angle of 40 deg., with *C B* the new vertical. *A B*, being half the wheel base, measures 1 foot.

$$AC = AB \times \textit{cotangent } 40 \textit{ deg.} = 1 \times 1.19 = 1 \textit{ ft. } 2\tfrac{1}{4} \textit{ in.}$$

Thus the center of gravity of the car, when standing on the track, must be 1 ft. 2¼ in. above the plane of the axles.

Example—A car has its center of gravity situated 9 in. above the plane of its axles, and has an 18-in. wheel base. Assuming that the car is symmetrical, how many degrees must it be tilted to balance on its front wheels?

Answer—45 degrees.

Glen Jean, W. Va., Examination

January 11-12, 1911

Fireboss Questions

Ques. 1—What are the qualifications and duties of a fireboss as required by law? What other qualifications should he possess which are not defined by law? State fully.

Ans. 1—The West Virginia mine law requires that a fireboss shall be a citizen of this State and have such knowledge of firedamp and other dangerous gases as to be able to detect the same with the use of safety lamps, and shall have a practical knowledge of the subject of the ventilation of mines and the machinery and appliances used for that purpose, and be a person with at least three years' experience in mines generating explosive gases.

In addition to the qualifications required by the mine law, the "fireboss" should be sober, reliable and a man of good character.

Safety Lamps

Ques. 2—(a) State in your own words the principle of safety embodied in the safety lamp. (b) How are safety lamps usually constructed? (c) Why are they usually made in a cylindrical form and within certain limits as to size and shape? (d) Under what conditions do they become unsafe? (e) What constitutes a good safety lamp? (f) Name six essential features of a good safety lamp for general work. (g) Are there any conditions under which the flame will pass through the gauze of a safety lamp?

Ans. (a) The safety lamp depends for its safety on the cooling effect of the metal gauze on the flame when an ignition of gas takes place within the lamp.

(b) They are usually constructed with an airtight glass surrounding the flame, the gauze being above it, in the upper part of the lamp. Where the air supply to the burner is brought into the lamp below the flame, there is usually a gauze below the glass also. The bottom of the lamp is usually the receptacle for oil, wick, igniters, etc.

(c) They are made in cylindrical form so that when an ignition of gas takes place in the lamp, the wires are all equidistant from the center or hottest part of the flame and all equally absorb, conduct and radiate the heat generated. It has been determined by experiment that if the diameter of the gauze is too great, the wires at the top of the gauze have more than their proportion of heat to dissipate, and for this reason a gauze cap is sometimes used, making, at the top, a double thickness of gauze.

(d) A safety lamp becomes unsafe, when an ignition of gas takes place in the lamp, and when it is allowed to stay in a gaseous mixture until the wires of the gauze are heated up to such a degree that they will ignite the gas outside the lamp, or, when the glass is broken, the gauze dirty, or the lamp unlocked or damaged in any way, or when a heavy current of air deflects the flame against the gauze. The safety lamp is also unsafe when it is placed in the hands of an ignorant, inexperienced, incompetent or uninstructed person. It should be constantly guarded against the possibility of breakage.

(e and f) Six essential features of a good safety lamp for general work are:

1. It must give good light and the glass should be of good quality and clear so as to make the utmost of the illumination.
2. It should contain oil enough to last a whole shift.
3. It should go out in a gaseous mixture.
4. The gauzes should be protected by a metallic shield.
5. The lamp should be strongly constructed.
6. It should have a lock that cannot be tampered with and the lock should show when it has been meddled with. The size of the lamp should be such as to admit of its being placed as near the roof as possible.

(g) The flame of a gas ignition will pass through the gauze of a safety lamp when the wires are sufficiently heated or when the lamp is placed in currents of high velocity.

Outburst of Gas

Ques. 5—If a large outburst of gas took place in your mine when all your men were at work, what would be your first consideration to prevent an explosion? Explain fully.

Ans. 5—All open lights should be extinguished and the men gotten out as rapidly as possible, through the intake airway. No one should be allowed to travel the return airway. The fan should then be "speeded up" so as to increase the quantity of air circulating in the mine as much as possible without causing a breakdown or disabling the fan.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

The Court of Commerce has begun consideration of the Hillsdale coal-car distribution case which has come up to it from the Interstate Commerce Commission, and already has had, on Oct. 11, an important hearing. In this case is involved the question of the distribution of cars to those coal companies which already own private cars.

The Pennsylvania railroad has had a rule that any company owning private cars should be given all its own cars available and that the number of these should be subtracted from the previously determined allotment to which the company's business entitled it. The Interstate Commerce Commission not long ago established a rule that private cars should be considered as railroad property. Thus in some cases the private cars of a mine would be taken away from it and given to another mine. Hence arose opposition on the part of the Pennsylvania company and of various private-car owners.

In the argument before the Court of Commerce it has been contended that the rule of the commission did not hurt the railroads and was intended to prevent discrimination as to the time and availability of coal cars at the mines. The railroad lawyers have argued that the commission had no right to establish a condition under its rulings, whereby cars would be taken away from their owners at any time and turned over to other competing operators for their use in shipping coal. It is believed that the Court of Commerce will attempt to deal with this subject at an early date.

Report from Bureau of Corporations

The Bureau of Corporations has just issued its complete report on the first section of its investigation of the iron and steel industry in the United States. In the course of the discussion of the United States Steel Corporation and its subsidiary concerns, considerable attention is paid to the question of coal holdings and coal values.

The purchases of coal made by the corporation are carefully surveyed. Since its organization, some substantial additions to its holdings of coal and coke property have been made. In December, 1901, it secured a lease of 50,000 acres of desirable coking-coal and fuel-coal property in the Pocahontas region.

Other important additions have been; the coal property of the Union Steel Company; 2650 acres in Fayette county, Penn., taken over with the Clairton Steel Company in 1904; 1200 acres of coking coal in the Connellsville region and 1072 beehive ovens originally belonging to the Hecla Coke Company; and 1766 acres variously acquired in the same region.

Coal Holdings of Tennessee Coal and Iron Company

In 1907 an enormous addition to the coal property of the corporation and an important addition to its coke property were made through the acquisition of the Tennessee Coal, Iron and Railroad Company. These properties are very extensive. The 1904 report of the company placed the total tonnage of coal at over 1,600,000 tons. The 1906 report stated that the coal reserves were, as computed by competent authorities, estimated to be 2,000,000,000 tons.

More careful estimates were made subsequently by agents of the Steel Corporation. The estimates of these agents grouped the resources in three classes, namely, "proven," "probable," and "possible." Their estimate of the coal property of the company follows:

	Proven	Probable	Possible	Total
	Tons	Tons	Tons	Tons
Coking coal	217,000,000	90,000,000	150,500,000	457,500,000
Steam and domestic coal	68,000,000	351,800,000	520,000,000	939,800,000
Total	285,000,000	441,800,000	670,500,000	1,397,300,000

In 1909 and 1910 the Corporation acquired extensive coal properties in Illinois and Indiana. An exceptionally important addition was made in June, 1911, through the purchase from the Pittsburgh Coal Company of about 7000 acres of coking-coal property, known as the Colonial Coke Company tract and also about 9000 acres of virgin or unimproved tracts of coal rights owned by the Monongahela River Consolidated Coal and Coke Company, the control of which is held by the Pittsburgh Coal Company. The total consideration was reported at approximately $17,800,000.

Value of the Steel Corporation's Coal Properties

The value of the original investment in coal and coke properties is estimated by the Bureau of Corporations as $80,000,000, although an estimate originating from a private source places it at $99,915,000. It is stated that the value of the coal lands has been materially increased by concentration of ownership. In consequence the Steel Corporation now estimates its coal property at about $47,000,000 more than does the Bureau of Corporations.

Alabama

Bessemer—Coal mines are again active throughout this district. Operators do not concede that there will be a falling off in production in Alabama this year.

Birmingham—On account of the increased demand for coal and coke, the Tennessee Coal, Iron and Railroad Company has started up the No. 6 Blue Creek coal mine, which has been idle for the last year.

The Tennessee Coal, Iron and Railroad Company has ordered from the General Electric Company eight motor-driven air compressors of the reciprocating type for its coke ovens at Corey. These will be used to raise and lower the coke-oven doors by remote control with compressed air.

Colorado

Denver—The sale of the Northern Coal and Coke Company to the Rocky Mountain Fuel Company, which has been pending for some months, has been announced here. The consideration was close to $2,000,000.

The sale included all the Northern Coal and Coke Company's mines, both in northern Colorado and in the southern part of the State.

As a result of the sale the Rocky Mountain Fuel Company will increase its stock to $8,000,000.

The American Fuel Company, with a capital stock of $1,000,000, has been formed to control eight mines in the northern fields with more to be taken over in the near future. The eight mines already controlled are in the vicinity of Louisville, Lafayette and Frederick.

Illinois

Peoria—The five self-appointed directors of the Wolschlag Coöperative Coal Company, who have for the past few months managed the affairs of the company, were ousted from their offices by the ruling of Judge Puterbaugh, Oct. 13, and the regular directors were reinstated.

Belleville—Nearly all the operators in the St. Clair county field appeared before the board of assessors recently and claimed a reduction in assessments, on account of the past unprofitable year.

Harrisburg—Eight miners were killed and eight others temporarily overcome by an explosion in O'Gara No. 9 mine, Oct. 23. The dead and unconscious were removed from the mine by rescuers, three of whom were overcome by gas, but were later resuscitated at a hospital.

The explosion occurred as the shifts were changing, and only 16 men were in the north entry, where it originated, although 360 had reported for work, but had not gone into the workings.

Two men were instantly killed, and six others, sent to the surface, died within an hour.

Indiana

Linton—The dullness of the coal market has caused the shutting down of mines Nos. 2, 4 and 21 of the Vandalia Coal Company. There are nearly 1000 men out of employment in the mines here. The strike at the Chicago and Indianapolis mine is still unsettled, the men having failed to arrive at a satisfactory agreement with the mine operators.

The Shirley Hill Coal Company is installing at its No. 3 mine a washer to clean coal for the market just as eastern coal is cleaned. This is the first attempt of the kind in the Indiana coalfield and the experiment is being watched with much interest by the other operators.

Brazil—Work on the new tipple at the Schrepferman Coal Company's mine south of this city has been completed and the mine will resume operation.

M. H. Johnson, who was appointed receiver for the Treager Coal Company, some time ago, has sold the mine and mining equipment to Oscar Schlatter and son. The new owners will begin operations at once.

A fire in the No. 8 mine of the Brazil Block Coal Company, Oct. 20, threatened the lives of 100 or more men. A rescue party, amounting to two cage loads, was organized and finally succeeded in extinguishing the fire. One member of the party was killed by a fall of rock; this was the only fatality.

Terre Haute—The Deep Vein Coal Company recently leased to the Deep Fourth Vein Coal Company the mine known as Deep Vein mine for a period of five years. The consideration specified is 10c. a ton for all coal mined and the lessee agrees to mine not less than 2000 tons of coal per day.

North Dakota

New Salem—The new machinery in the plant of the Dakota Coal Products Company at this place has been installed and is now in working order. The building and the mine are lighted by electricity. The first electric-power coal-cutting machine has been placed in use.

Kentucky

Louisville — The Consolidation Coal Company, of Baltimore, has under advisement the opening of two additional coal mines in the Miller's Creek district at an approximate cost of $600,000.

Barbourville—Two new coal mines are being opened on Brush creek. The Brush Creek Coal and Manufacturing Company is making an opening near Jones' trestle, on the Cumberland railroad. The incline is being graded and a siding put in. The Gibson-Carr Company, of Middlesboro, is putting in a plant on the Croley lease on Tye fork, and both companies expect to be shipping coal by the first of the year.

The Interstate Coal Company still retains the Brush Creek coal plant, which it leased some months ago and closed down.

The Greasy Creek Coal Company is opening a new mine on Greasy creek, near the Knox-Bell county line. A long extension track is being added to the Bell-Jellico railroad. The Continental Coal corporation is running all of its fourteen mines in Bell and is calling for more miners.

The Martin's Fork Coal Company has been organized recently in Bell county and will develop land held by it near the town of Harlan.

Ohio

Columbus—The tipple, power house and other buildings of the Black Diamond Coal Company at Amesville are nearing completion and when finished will make one of the best equipped mines in the country. All buildings are of reinforced-concrete construction, and perfectly fireproof. The management hopes to be mining coal by the first of November.

The Big Run Mining Company, of Bellaire, has been incorporated with a capital of $150,000 to mine and sell coal.

As a result of the agitation against the wholesale stealing of coal from the cars of the Big Four railroad while passing through Columbus several changes have been made lately in routing coal. The Norfolk & Western is now turning its cars for local business over to the Big Four at Urbana while the Hocking Valley is switching at the Mound Street crossing.

Pennsylvania

Bituminous

Pittsburg—It is reported that a merger of the interests of the Pittsburg Coal Company, Monongahela River Consolidated Coal and Coke Company, H. C. Frick Coke Company and the Ellsworth Collieries Company, owned by the Lackawanna Steel and Iron Company, is being arranged, and that these interests will be taken over by the United States Steel Corporation.

Government representatives are at work in the Irwin coal-mining field, gleaning information regarding the recent strike there which lasted 18 months and involved over 18,000 miners. They will make a report of their findings to Congress when it convenes in December and it is expected that some action will be taken by that body regarding the industrial struggle.

Engineers of the H. C. Frick Coke Company have made preliminary surveys of the coal and coke properties in Washington county, purchased recently from the Pittsburg Coal Company and the Monongahela River Consolidated Coal and Coke Company, preparatory to building additional ovens.

The Crucible Coal Company of Pittsburg is erecting 250 coke ovens and contemplates building 350 ovens additional at its mines and docks at Rice's Landing. A contract has also been awarded for the construction of three eliptical reinforced-concrete shafts, each 150 ft. in depth, two coal shafts and one air shaft. There will also be two railroad and one river tipples, the structural steel for which will be furnished by the American Bridge Company. Five new tow boats and 90 steel barges are in course of construction, which will be utilized in transporting coal from the company's mines, to Midland, Penn.

Anthracite

Wilkes-Barre—Carelessness on the part of an employee is given as the cause of a fire in the No. 9 colliery of the Lehigh & Wilkes-Barre Coal Company, at Sugar Notch, on Oct. 14, shortly after the men had left the mine. The fire was found within a short distance from the mule barn, and for a time it was feared that the blaze would develop into a serious mine fire.

Scranton—Work has been completed on the new concrete breaker of the Lackawanna Coal Company, at Taylor, and the officials are making plans for its opening within a few months.

The first meeting of the Pennsylvania State Anthracite Mine Cave Commission since its organization late last June, was held recently in Scranton. W. J. Richards, of Pottsville, presided, and George M. Davies was secretary.

The next meeting will be held the second week in November. It will be probably several months before the commission will have completed enough of its labors to interest the public, for much detail work must be done before anything definite as to remedial legislation can be formulated for the next legislature.

Pittston—The discovery of an expected cave-in on the tracks of the Delaware & Hudson railroad, saved a train from

plunging into a hole on the curve below the Cork Lane station. Officials of the Erie company had previously notified the Delaware & Hudson company that they were going to remove the pillars under the tracks and that a settling was inevitable.

Washington

Seattle—There seems now some prospect that the valuable deposits of anthracite discovered some years since in the neighborhood of Glacier, in Whatcom county, may at last be utilized in this State, where such a coal is imperatively needed. It is believed that the forestry service will consent to patents being issued to half a dozen claims. If this is done, a tramway four miles long will be constructed from the mines to the Bellingham Bay and British Columbia railroad at Glacier, and the coal can then be put upon the market.

There is apparently no doubt that the coal measures are large and unbroken. The coal itself is of good quality. It is the only workable deposit of hard coal of the kind in the State so far discovered, and the coal is badly needed here, where even the local soft coals are constantly advancing in price, with production never fully equal to the demand.

West Virginia

Fairmont—Fifty four-room brick houses have recently been built at the Annabelle mine of the Four States Coal and Coke Company, near Worthington, W. Va., and now are ready for occupancy. This is one of the best drained, ventilated and equipped mines in the State.

Grafton—The Maryland Coal Company, with mines located at Windell, has been reorganized, and a new board of directors and new officers have been elected.

Canada

Cape Breton, Nova Scotia—The Glace Bay mines of the Dominion Coal Company have this summer had the best season in their history. The company has now 12 collieries in full operation, and four in course of development. In the month of August the output was 387,927 tons, about 16,000 tons in excess of any previous monthly production. For September the output was 324,311 tons, making the total output for this year 2,973,791 tons, compared with 2,607,591 tons at the end of September, 1910.

The two years agreement which the Dominion Coal Company has with the Provincial Workmen's Association expires at the end of this year.

Alfred, Ontario—The mines department of the Canadian government has now about 1000 tons of peat fuel manufactured at its demonstrating plant, which will be disposed of at $3.50 per ton. The experiments have shown that in order to manufacture this fuel on a commercial scale, hand excavators will have to be replaced by mechanical excavators. The present cost is about $2 per ton.

Personals

S. K. Smith, formerly with the Vintondale Colliery Company, Vintondale, Penn., has opened an office in St. Louis, Mo., as a mining and consulting engineer.

Dr. C. W. Hayes, who last Saturday resigned as chief geologist of the U. S. Geological Survey, has left Washington for Tampico, Mex., to assume his new duties as first vice-president and general master of the exploitation department of the Compania Mexicana de Petroleo "El Aguila," at a salary of $25,000 gold per annum. For two years he has been in charge of the exploratory work of these oil interests, having taken leave without pay two months each year for this purpose. He, therefore, goes to his new work having a complete familiarity with the conditions under which oil productions must be carried on in Mexico.

In transmitting to Secretary Fisher the resignation of Doctor Hayes, Director George Otis Smith, of the Geological Survey, paid him high tribute, saying in part:

"I deem it my duty to bring to your attention my estimate of the loss which the public service sustains. As his associate for 15 years I know and appreciate the scientific attainment and the administrative thoroughness with which he has devoted himself to the Geological Survey, first as a field geologist, and later as its chief geologist, a contribution that has meant much in bringing the geologic work of the Survey up to its present high degree of efficiency. Doctor Hayes' standard of the highest attainable accuracy and his policy of absolute fidelity to scientific truths, whatever the consequences, have won for himself the respect of his associates, and for the work under his charge the confidence of the public."

Obituary

Eugene Nelson, for a number of years prominently identified with the coal trade of Boston and New England, died Oct. 16, at his home in Malden, Mass. Mr. Nelson was vice-president and sales agent of the Metropolitan Coal Company of Boston.

John R. Walsh, banker, publisher and railroad owner, died at his home in Chicago, Oct. 23. He was an important financial power in Chicago and the Middle West until 1905, when speculations in Indiana coal lands and railroads brought about a collapse of all his interests and led to his subsequent sentence to the Federal penitentiary for misappropriating the funds of the bank of which he was at the head.

Recent Coal and Coke Patents

United States

Mine-car stop; George W. Jenkins and Edward Lowry, of Nelsonville, Ohio. No. 1,004,652.

As shown in the sketch, Fig. 1, this device consists of two cams, mounted on shafts which lie parallel to and just outside of the rails. A spring tends to keep the cams in a vertical position where they act as car stops, the inside face of the cam being curved to suit the car wheel.

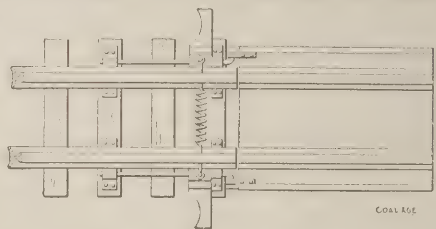


Fig. 1. Mine-car Stop

The cam shafts extend out into an elevator or cage way, and their projecting ends are given a right-angled bend. When the cage descends to a level with the landing, projections on it engage the bent-out portions of the cam shafts and throw the cams down toward a horizontal position, releasing the car.

Rail and rail-tie plate; Harry E. Haight, Marshfield, Wis. No. 1,004,778.

Signaling system for mines; Edgar M. Johnson, Hancock, Mich., assignor of one-half to Ross D. Blackburn, Hancock, Mich. No. 1,004,879.

Axle lubricator; George C. Benjamin and John C. Benjamin, Barre, Vt. No. 1,004,972.

Tie and rail fastener; William G. Lucas, McKeesport, Penn. No. 1,005,050.

Great Britain

An improved apparatus for quenching, screening and loading coke from byproduct coke ovens; J. Mackenzie, Middlesbrough, England. No. 24,086 of 1910.

Improvements in coal-washing machinery; A. Sheppard, Bridgend, Glamorgan, Wales. No. 29,307 of 1910.

Trade Publications

Jeffrey Manufacturing Company, Columbus, Ohio, Catalog No. 26-A, Mine Fans, 6x9 in., 36 pp., contains numerous illustrations and engineering formulas.

Roberts & Schaefer Company, Chicago, Ill., bulletin No. 24, Modern Coal Washing Plants, 6x9 in., 42 pp. A large number of coal-washing installations are described and illustrated.

Ingersoll-Rand Company, New York, pamphlet 6x9 in., 12 pp., descriptive of class "N E-1" power-driven single-stage air compressors.

Yarnall-Waring Company, Philadelphia, catalog 7½x9½ in., 12 pp., descriptive of "Lea" water-flow recorders.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The condition of the coal market is slowly improving as the season advances, and coal men generally appear to have optimistic views for the winter trade. The late season has no doubt seriously affected the market in most sections, but the tonnage reports of the large carriers are equal to or greater than those for the same period last year, which is encouraging.

In the Eastern market, trade is reported good almost without exception. While there is little demand for spot coal, contract is moving well and strike talk may cause an unusually active market this winter. The Lake shipment from Buffalo has been far in excess of any previous season, and demands for anthracite are, in some instances, becoming urgent.

Lake shipments in the middle East are about finished, and no improvement has appeared in the Pennsylvania market, especially the coke trade, which is unusually heavy. The demand for Ohio and West Virginia coals is increasing, with a consequent steadying of prices, and the tonnage report of the Chesapeake & Ohio railroad for August shows an increase of 14 per cent. above that for the same period last year.

The smallest car surplus, since Nov., 1910, is reported at Chicago, and it is said some mines on the Illinois Central have been unable to get cars because of the strike on that line. Trade continues unusually poor in Indiana, with apparently no hopes of improvement.

In the Rocky Mountain States the market is reported normal or active. The strike situation on the Harriman lines remains unchanged, and there is a serious car shortage as a result of which many mines are behind with their orders. The mild weather on the Pacific coast has left conditions unchanged with the market rather dull.

Boston, Mass.

Tidewater prices on bituminous are up, so far as deliveries alongside and on cars are concerned, but the net figures at the mines do not yet show the hoped for improvement. This is due to the volume of coal that is being applied on contracts, and to the continued shortage in water transportation. Current sales of cargoes are so few as to be negligible in amount, and the sharp advance in marine freights has not yet been made apparent to buyers less closely in touch with the market.

There is generally, however, a better tone than last week, and while the weather has been continuously rainy and mild, it is felt that we are now facing the seasonable demand that is always so welcome to the wholesaler. Inquiry for inland shipments is active and we shall soon be settling into a November market. With wise prophets pointing to the thick feathers on the birds, and salesmen making knowing remarks about strike prospects, it is fair enough to say that the fall season will be a good one, both in anthracite and bituminous.

The demand for anthracite is getting to be urgent, and there is delay with almost all the shippers. Barges have been moving very slowly along the coast, there having been just one day during the past week when there was any considerable tonnage arriving. With no longer any inducement in prices for anticipating their needs, many of the smaller dealers had postponed placing orders, with the result now that they are all insistent on prompt delivery.

All-rail bituminous is looking up, and prices are slightly better for spot coal. A good tonnage is coming forward on contracts. Georges Creek is being held at \$1.50 to \$1.60 at the mines, with the better brands of Cambria county, South Fork district, selling at from 10c. to 25c. less.

Pocahontas and New River have been advanced, on cars, Mystic wharf, Boston, and at other points in proportion, to \$3.43 and \$3.53, more nearly the level at which the spring prices opened, but these figures are really no better, from a coal standpoint, than were the prices of a fortnight ago, at 20c. less, that amount representing the recent advance in water freights. Coal, f.o.b. Hampton Roads, remains at or around \$2.50, or \$1.10 at the mines, less the selling commission, not by any means a remunerative figure for some of the mines.

Marine freights from the Virginia ports are now firm at 75c. to 80c., 2500 tons and upward, with very little tonnage offering. It rather looks as if there might be a still further advance, and if there is we are likely to see a more active bituminous market.

New York

Although there is no letup in the demand on contract, the standing tonnage at the New york piers is today somewhat above the amount of the normal supply, and the spot market shows some signs of weakness. As there has been no car shortage to restrict the output, and with the railroad movement prompt, coal is arriving here faster than most shippers are prepared to dump it.

There is scarcely any new business coming into the market at this time, and the trade has to look to contracts for disposition of accumulations. Contract business is heavy enough to keep the better grades of steam coal moving ahead of demurrage, but inferior steam coals, which are not contracted to any extent, are not in so fortunate a position, and shippers of these grades are experiencing difficulty in avoiding detention penalties. At some of the piers where accumulations have been heaviest, those shippers who have brought down more coal than they could readily provide disposition for, have been embargoed.

On the other hand, while the market is so weak for the lower grades of steam coal, it is noticed that some of the shippers of fancy grades of Pennsylvania steam coals are having all they can do to take care of the deliveries required of them on their contracts, and in some instances consumers buying of them have supplemented their supply by purchasing on the market.

Prices, except for free coal on demurrage, show little, if any, change from those ruling for the past two or three weeks, ranging from \$2.35, f.o.b., for West Virginia steam coals; \$2.55 for ordinary Pennsylvanias; \$2.65 fair-grade Pennsylvanias, and \$2.75 to \$2.85 for the better grades.

All-rail business in the territory adjacent to New York City is moving in good volume on contract, but as in the tidewater market, there is but little, if any, spot inquiry, owing, no doubt, to the fact that consumers are receiving from their regular suppliers all the coal needed for immediate use.

Buffalo, N. Y.

The demand for soft coal improves slowly from week to week and is now in a volume to be fairly satisfactory to the trade except for the low prices, which will hardly be likely to advance this fall unless there is a stir in iron, which is not looked for. Many iron manufactories are reporting a good run of trade, and this is enough to satisfy a very fair demand.

The complaint of poor business in soft coal is almost entirely on account of the

small margin of profit to the jobber and still smaller profit to the operator. There is much building on the expectation that the stocking-up demand, against expected labor troubles next spring, will begin soon after the first of the year. This keeps all members of the trade eager to maintain their present tonnage in order to be in close touch with the consumer the moment he begins to lay in a stock to hold till the labor difficulties are adjusted.

The prices of bituminous continue rather weak at $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack, with Allegheny Valley 15 to 25c. lower. There is no improvement in coke, which is quotable at former prices, $4.25 for best Connellsville foundry, down to $3.50 for stock coke.

The anthracite circular prices remain without change, but such is the natural demand for chestnut in excess of production that independent mine owners are already sending out notices that they expect to ask a premium for that size in a short time. At present the shortage is almost entirely in the stove size, with egg very plenty.

The Buffalo city market for soft coal holds up well, and there is a steady improvement in the demand for hard coal, though the activity of the natural-gas companies is cutting in on the anthracite trade, especially in the residence districts, where the extension of gas mains is going on at a rapid rate.

The heavy movement of hard coal by lake continues. With about 300,000 tons in excess of any former season to date shipped, the average loading is still more than 100,000 tons a week, which will continue till either the lake season closes or room on the upper-lake docks is exhausted. There is considerable delay in unloading coal at most of the docks on Lakes Michigan and Superior, but it is much more serious in the soft-coal trade than with hard coal as yet.

The movement of soft coal from the mines, which was somewhat interrupted by freshets, has been resumed fully. As a rule the filling of orders is much more prompt than it used to be, for which reason the consumer is carrying only a light supply as a rule, confident that he is in close enough touch with the mines to make this course quite safe.

Philadelphia

There has been practically no change in the retail situation since our last review. All the dealers report good business for the various sizes of coal. Stove is getting to be quite scarce, and dealers' orders are not filled as promptly as they would like. The past week, while not at all cold, at the same time has been damp and gloomy, and a small fire in the furnace has been necessary to keep the house in a good, dry condition. Taking it all in all, the anthracite trade is good.

In the wholesalers, the same optimistic spirit still prevails. All sizes of coal are moving off promptly, and the companies report large increases over their tonnage for the corresponding period of last year. Chestnut coal is moving in such large quantities that if the demand keeps up, stocks will soon be depleted, and the individuals will be asking a premium for their product. Prices, egg and stove, $3.75 at the mines; chestnut, $4; pea, $2; buckwheat, $1.50; rice, 90c. This last size is going to be very scarce this winter, from the present outlook, and it is understood that the companies are very chary about making any new obligations.

There is a slight improvement in bituminous circles, particularly with certain coals. It is understood that some coal was on demurrage at this point, and quite a sacrifice had to be made to move it off. However, this may be only an individual case, as most of the bituminous operators insist on having their orders in hand before shipping the coal down to tidewater, rather than taking a chance on placing the coal in the open market.

Pittsburg

Bituminous — Manufacturing demand for coal has shown no improvement, although at this season there is usually a slight increase in the movement, for the purpose of increasing stocks. Industrial conditions in this district are hardly as good as they were a month or two months ago. The domestic trade has also been slack, dealers buying with a great deal of reserve.

Lake shipments have been greatly curtailed. Instead of the spurt toward the close of the season, which has long been expected, the season is closing unusually early. Less difficulty in securing vessel room is being encountered than was expected, as the iron-ore movement is holding out quite well. Prices continue irregular, and the regular season prices are being uniformly shaded, sometimes to an extreme degree. Slack has not shown the strength which usually occurs at this time, owing to decreased production through the curtailment in shipments of ¾-in. in the lake trade. We quote ordinary market prices, which are below the nominal figures, but are sometimes shaded further: Nut, $1@1.05; mine-run, $1.05@1.10; ¾-in., $1.15@1.20; 1¼-in., $1.25@1.30; slack, 40@50c. per ton at mine, Pittsburg district.

Connellsville Coke—Purchases of odd lots of prompt furnace coke continue at the unchanged price of $1.50, which has represented the market for several weeks. The total turnover in the past fortnight in prompt furnace coke has been somewhat in excess of 5000 tons. Nothing has been done in contract coke, there being very little uncovered consumption for the balance of the year, and this being committed to purchases of prompt coke from time to time. The matter of contracts for the first half or all of next year has not been taken up yet. Furnaces are in no mood to buy, and producers are in no hurry to sell. They realize that it is practically impossible to secure any great advance over the present spot market, and some of them also appreciate that a continuance of anything like present prices will mean financial embarrassment to some of the operators. It is impossible to exist on $1.60@1.65 coke if the coal acreage is carried at the prices which some operations have paid, and in many cases a large proportion of the acreage price paid is carried in bonds. The situation has been growing serious and the outcome is not easy to foresee. There is no influence apparent to put up the price and there is no contract price quotable. Operators would like to obtain about $1.75 for first half, but buyers will not close in the near future at such a price. Foundry coke has been quiet, and remains quotable at $1.80@1.90 for prompt and $2@2.25 for contract.

The *Courier* reports production in the Connellsville and Lower Connellsville region in the week ending Oct. 14 at 310,205 tons, a decrease of 4000 tons, and shipments to Pittsburg, at 3728 cars, 4690 cars to points west, and 1059 cars to points east, a total of 9477 cars, which is a decrease of 150 cars.

	September 1911	Increase or Decrease	January 1 to September 30, 1911	Increase or Decrease
Anthracite coal, short tons	839,754	35,540	8,489,450	450,173
Bituminous coal, short tons	3,629,042	101,838	30,504,343	183,350
Coke, short tons	918,294	13,671	7,880,607	2,311,406
Total	5,387,090	123,707	46,874,400	1,677,883

Columbus, Ohio

The lower temperature which prevailed during the past few days had the effect of making the domestic trade in Ohio more active and brought the market out of the slough into which it was forced several weeks ago by the continued warm weather. As a result orders from dealers are better and the general tone of the market has improved.

The lake trade is continuing active and the records compare very favorably with those of the corresponding period in 1910.

There is some congestion at the docks of the upper lake ports but not sufficient to seriously affect the trade in this State. Up to the present time the New Pittsburg Coal Company has about equaled its lake record of last year, when about 560,000 tons were shipped, and the Sunday Creek Company, is moving slightly more than last year. The Hocking Valley docks at Toledo have loaded 2,058,000 tons since the opening of navigation.

The steam business continues steady but there is nothing to indicate an improvement. Many factories are taking only a small amount of fuel and there is no disposition to stock up for the future. The demands for railroad fuel are not very great as the freight movement is comparatively light at this time.

Operations in the various Ohio fields have been fairly active during the past week, the production being about 80 per cent. of the average. In the strictly domestic fields, considerable activity prevails, and in the fields supplying lake coal there is a good production.

Retail trade is a little better with prices ranging from $3.25 to $3.50. The heavy rains of the past few days have made it difficult to make deliveries and there is a disposition on the part of the large users to wait until later to place their orders.

Chicago

Chicago coal dealers predict a severe cut in car service. The current report of the American Railway Association shows that the total car surplus amounts to 48,854 cars. This is the smallest surplus reported since November 23, 1910. During the two weeks ending Oct. 2 the total car surplus decreased 9528 cars.

The Illinois Central strike situation is still an important factor in the coal trade. Despite statements issued by the company to the effect that business is being handled in the usual way, coal dealers declare that they are not getting the same service that was furnished prior to the strike. It has been learned that some mines located on the lines of the Illinois Central have been unable to move any coal. Before the strike was called Springfield coal was quoted at $1.25 in Chicago and $1.40 in the country. The minimum now is $1.40 with a tendency to add 10c. a ton. As a result of the strike the market has been so strengthened that the country and city prices have reached a parity on the higher level.

Prices direct from the mines in net tons to retail dealers and steam users on spot shipments are as follows:

	Chicago	F.o.b. Mines
Clinton:		
Domestic lump....	$2.17@2.27	$1.40@1.50
Steam lump......	2.00@2.10	1.25@1.35
Mine-run.........	1.77@1.82	1.00@1.05
Screenings........	1.22@1.32	0.45@0.55
Pocahontas and New River:		
Mine-run	$3.00@3.05	$0.95@1.00
Lump and egg....	4.05@4.30	2.00@2.25
Springfield:		
Domestic lump....	$2.22	$1.40
Steam lump......	1.92@2.02	1.10@1.20
Mine-run.........	1.82@1.87	1.00@1.05
Screenings........	1.22@1.32	0.40@0.50
Sullivan County:		
Domestic lump....	$2.35@2.45	$1.50@1.60
Egg..............	2.25	1.40
Steam lump......	2.10	1.25
Screenings........	1.22@1.32	0.35@0.45
Coke:		
Connellsville......	$4.50@4.65	
Wise county......	4.50@4.65	
Byproduct, egg and stove..........	4.95	
Byproduct, nut....	4.55@4.65	
Gas house........	4.95	

Cincinnati, Ohio

The coal situation here is improving. The coal men are picking up orders in larger volume than heretofore, and the indications are that, while slow, there is a general bettering of conditions. The most backward are the fine coals for steam purposes, while the best is in domestic lump, which has revived considerably. This, despite the fact that there has not been the cold weather that is usual at this time of the year.

The only authoritative change in prices recently has been the circular drop in Pocahontas lump from $2 and $2.10 to $1.90 and $2. It is said by some who were opposed to this change in prices that it was unwarranted by existing conditons, excepting internal matters which have come to the surface in spots. In connection with this, it may be said that an official announcement concerning Pocahontas matters of wide importance, would not be surprising within a few days. About Nov. 1 is the date now set, although it may not become effective until the new year.

Charleston, W. Va.

There is some feeling of activity in the coal trade over that of last week, due to the increase in demand for winter shipments. This increase is general—the east and west sharing almost equally. Prices, too, it is claimed, have received a slight boost, but as usual it is almost impossible to ascertain just what the prices are, since there is little attempt at uniformity along that line.

Indianapolis, Ind.

The present condition of the coal-mining business of Indiana is best illustrated by the thousands of empty flat cars on side tracks in the mining districts. As a rule at this season of the year, there is always a fight for empties and charges of partiality and discrimination freely made. Every side track of the coal-carrying railroads has its capacity taxed by empty coal cars, while during previous years the miners have worked nearly steadily during this month.

Viewing the field over, there has been little in the way of diversity in Indiana to stimulate the coal trade during the past week. The operators, however, are optimisitic and maintain the prices at the mine in the face of a small demand. There is apparently no foundation for report that the operators are restricting the output for the purpose of controlling prices. Compared with prices at this period last year, it is claimed that present ones are a shade lower for all grades of coal. With sufficient cars the operators could overship the market, but they naturally have no wish to do so as they are confident there will be a revival of business generally after the first of the year.

St. Louis, Mo.

The higher-grade coals from the Standard field are bringing from $1.75 to $2.25, with the demand slightly increased over that of last week. The middle-grade coals from the standard field, such as Mt. Olive and Staunton, are bringing from $1.15 to $1.35 at the mines, for domestic lump and other sizes are bringing what the market will pay.

6-in. lump	$1.05@$1.15
3-in. lump	0.95@ 1.00
2-in. lump	0.90@ 0.95
Mine-run	0.75
Screenings	0.25@ 0.30

There is very little Springfield coal coming in, and some from Saline county.

The Carterville prices are as follows, f.o.b. the mines:

6-in. lump	$1.40@$1.50
3x6 egg	1.40@ 1.50
No. 1 nut	1.15@ 1.25
No. 2 nut	1.02@ 1.15
Mine-run	1.00@ 1.10
Screenings	0.35@ 0.45

Franklin county coal is selling at the following prices:

6-in. lump	$1.55@$1.65
3x6 egg	1.55@ 1.65
No. 1 nut	1.35@ 1.45
No. 2 nut	1.15@ 1.20
Mine-run	1.10
Screenings	0.50

Colorado

The lump and nut grades advanced 25c. per ton, Oct. 1. The increase has not tended to lessen the volume of trade, as it is evident current shipments are being sold from the cars and not placed in stock. The quantity of storage coal in the territory is comparatively light, and especially in the southern portion is this feature most pronounced. A high percentage of the orders for early delivery are traceable to this district.

The car situation shows no improvement. Available cars are barely adequate to fill orders placed by the mines working on the present basis. Some delay has been reported chargeable directly to car shortage, but of trivial consequence.

Steam orders show a slight gain over the previous week, due generally to the season's advance. However, renewed activity in railroad and industrial traffic is obvious. The sugar-beet plants are now operating and a good many alfalfa mills have al-

ready opened this year's campaign, which will provide a market for considerable steam coal.

No change is perceptible in the coke demand, which is considered normal at this time with prices firm.

Salt Lake City, Utah

There is no relief promised from any source except the weather man, and he has been doing very well for us the past few weeks. The mines are still operating on reduced time, due to a shortage of cars. On Oct. 18, but one mine in the State operated, and that only half a day. Cold weather in Idaho and Montana has increased the demand on Wyoming mines, and they are about 30 days behind orders. This means that Utah will get but little coal from that source.

Local retail trade is consistent with the weather. Stocks are diminishing gradually and a cold snap would be serious. Lump coal at the Utah mines is $2.40, nut $2.15 and slack $1.25. Wyoming lump costs $2.50, nut $2.25 and slack $1, f.o.b. mines. There are rumors of an advance both wholesale and retail, but nothing definite has developed.

New Mexico

The New Mexico mines show but little change in the volume of business over previous week. A slight depression in railroad orders is observed, which is counterbalanced by an increased requirement of commercial coal. Western New Mexico is operating full time with an occasional delay, due to short car supply. The prices in this district advanced 25c. per ton, Oct. 1, and remain firm with a constant demand.

Portland, Ore.

This week brought almost summer skies and summer sunshine; hence the consumers are not giving serious thought to the fuel problem as yet. Prices remain the same as last week and there is no indication of an immediate change. Only a severe and long cold spell will have the effect of driving values high this winter, for much fuel has been put in during the summer. No new cargoes have been reported as listed for this port at Australia, the number of vessels on the board reported as heading for this port being only three or four.

Following are the prices asked here, per ton, including cost of delivery to points within the city proper:

Japanese	$7.50	
Washington lignite	$7.00@ 7.50	
Australian	10.00@10.50	
Rock Springs, Wyo.	10.00@10.50	nut $9.50
Diamond, Wyo.	10.00	
Carbon Hill, Wash., lump	10.50	
Carbon Hill, steam	7.50	
Newcastle, Wash.	7.00	
Beaver Hill, Ore.	9.00@ 9.25	
Blacksmith coal	17.00	

San Francisco

The arrivals of coal for the past week by water are as follows:

British Columbia	1850 tons
Newport News (for U. S. Navy)	5768 tons
Total	7618 tons

Market conditions have not changed during the past week, and continued warm weather, the warmest of the year, has caused a decrease in domestic consumption. Retail dealers, taking advantage of the fair weather, are stocking up for their winter supply.

The effect of the railroad strike of shopmen is, as yet, scarcely felt in the coal market. Coal, being an imperishable article, would be one of the first commodities to be sidetracked in case of lack of motive power or other equipment, but up to time of writing it seems to be coming through on regular time.

Prices for the week remain unchanged, and are as follows, per short ton:

Wellington—clean	$8.00
Wellington—average	7.50
Australian—clean	8.00
Australian—average	7.50
Seattle—clean	6.50
Seattle—steam	5.00
Utah, Wyoming and New Mexico—clean (for domestic use only)	8.15
Pennsylvania anthracite	15.00
Welsh anthracite	13.50
Colorado and New Mexico anthracite	12.50
Cumberland—smithing	12.50

The inquiry for steam coals remained quiet, and with supplies of both large and small still in excess of requirements, prices tend to further easiness. A comparison of exports for 1910 and 1911 shows but little change. Quotations are approximately as follows:

Best Welsh steam coal	$4.02
Seconds	3.72
Thirds	3.66
Dry coals	4.08
Best Monmouthshire	3.72
Seconds	3.60
Best Cardiff small steam coal	2.10
Seconds	1.86

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage, and for cash in 30 days, less 2½ per cent.

For prompt loading admiralty steams fully maintain their position, while the cheaper classes of large, in view of a better inland demand, are now firmer. Smalls of all classes are, however, exceptionally weak.

For forward delivery business is difficult to arrange in view of the possibility of further labor troubles.

Total exports of coal from Great Britain for September with comparative statement with September of last year was as follows:

	September		First 9 Months	
	1910	1911	1910	1911
Total anthracite	215,595	217,319	1,812,352	1,762,204
Total steam	4,096,835	4,289,349	33,831,913	34,735,081
Total gas	1,012,224	918,305	7,711,341	7,743,871
Total household	157,690	124,479	1,118,538	1,098,581
Total other sorts	228,762	238,198	2,050,733	2,278,953
Totals	5,711,106	5,787,650	46,524,877	47,618,690
Total of coke exported	87,409	94,403	658,378	711,697
Total patent fuel exported	101,402	118,799	1,139,144	1,236,582
Total coal, coke and patent fuel	5,899,917	6,000,852	48,322,399	49,566,969
Coal, bunker, for foreign trade	1,789,126	1,681,507	14,528,745	14,346,947

British Coal Market

There are many causes which made the condition of the British coal industry rather a disturbed one. There is a shortage of railway equipment, an inadequate supply of shipping tonnage available, the labor outlook is uncertain and there is still a sudden and sharp demand for house coals. The last feature of the market is growing less as the public needs are supplied, but manufacturers and industrial concerns are still stocking against emergencies.

On the whole the markets are much firmer, the output big and future prices are considerably enhanced as compared with the prices ruling a year ago; there is an advance of about 48c. per ton all around. Patent fuel and coke trades are practically stationary, as they have been for some time past, while pitwood is very irregular.

German Coal Trade

Coal production of the German Empire for the eight months ended Aug. 31, is reported as follows, in metric tons:

	1910	1911	Changes
Coal	99,719,729	106,176,645	+6,456,916
Brown coal	43,948,178	46,897,544	+2,949,366
Total mining	143,667,907	153,074,189	+9,406,282
Coke trade	15,373,605	16,631,800	+1,258,195
Briquets trade	12,593,688	14,044,936	+1,451,248

Of the briquets reported this year 10,760,172 tons were made from brown coal or lignite.

The foreign coal trade of Germany for the eight months ended Aug. 31 is reported as below, in metric tons:

	Exports	Imports	Excess
Coal	17,340,092	6,981,230	Exp. 10,358,862
Brown coal	38,478	4,544,188	Imp. 4,505,710
Coke	2,965,933	402,626	Exp. 2,563,307
Total	21,942,389	12,068,744	Exp. 9,873,645

The exports this year included 8161 tons of coke to the United States.

Moments with the Advertising Editor

A Department for Subscribers Conducted
by the Service Department of Coal Age

"Anybody who can write, can write an advertisement. But the question is whether it will sell anything or not," was the statement of one of the biggest general-magazine advertisers of the country the other day.

Is this a fact?

Is a set of rhymed words that looks like a poem when printed on a page, but that never stirs anyone to an iota of feeling, a poem? Is a brain which never thinks, a brain? Is a salesman who never sells anything a salesman?

We don't think so; neither do we think a half-page or a page or a double page of words about something that is to sell, but which never induces anyone to buy it or investigate it, an advertisement.

An advertisement means at core a thing that makes somebody *turn to* something.

If the advertisement is worth its name, it will *turn* certain people who are interested in that class of goods to the particular representative of that class it refers to. It turns them because it makes them see in that product some certain characteristic that, they think, would constitute it their most profitable investment. And if the investigation verifies this impression, such "turnings-to" mean sales.

That is an advertisement.

And herewith another thing becomes apparent:

A real advertisement cannot be written about inferior goods.

When you see an advertisement, so called, that is all vacuous general statements, you can be sure of one of a brace of things:

Either the subject under discussion won't bear scrutiny.

Or the author of the copy didn't know how to write an advertisement.

You can't go to particulars about goods whose makers have spent most of their time in building up the glossed-over impression that their goods are as good or better than the next man's "because they are." It is the particulars behind the "because" that the latter-day buyer is wrapped up in.

Particulars sting down to those little differences, *and to the big differences which the little ones hide*, that appeal to the man who thinks before he acts, and who pays small attention to an advertisement that does not make him think. Such a man is quite apt to believe that "wide-as-the-sky" statements are the refuge of the lagger.

Of course they may not be.

Poor advertisements can be written about good products, and those same goods sell mightily, too. They may have no competition, or no competition at all in quality, or else the sales may be impelled by costlier ways of publicity for which, as we said last week, the buyer foots the bill in the end.

All this gets us to our point:—

COAL AGE advertisements not only tell the truth, *but most of them tell it so as to bring action.*

"Two and two make four" is true enough; but its repetition has no value—it *does* nothing.

"This machine is right for you because it is this and this, and this, and does this"—*that* can be both true and be written in such a way as to create instant desire to see, to investigate, to buy that machine.

We, the Service Department men who write COAL AGE advertisements, are trained to take advantage of this one big opportunity—that, in the case of a specialized paper like COAL AGE, every individual of our multiplied print-salesman goes *direct to a buyer or a person concerned or interested* in the buying of the thing advertised. We know every lost word may mean a lost sale

We write these advertisements fully as much to serve you as to serve the advertiser whose goods they describe. There is where the full idea of "service" comes in.

When we put together a convincing advertisement that turns you to investigate something in COAL AGE Selling Section and then, quite likely, to buy that thing, we perform a service for you by getting you to as efficient, or the most efficient machine, appliance, whatever it be, that the market can give you—without the "exploration-worry" on your own part after a thing that is at once reliable and suited for the immediate purpose.

COAL AGE advertisers hand over to us the writing of their advertisements because they feel we can do it most effectively; they give us their confidence.

And just as this confidence is thrown to the winds unless we write these advertisements effectively, convincingly, so this effectiveness goes to the winds unless the advertisements are *read.*

But when COAL AGE was projected to meet the need in the coal-mining field for a weekly paper for the ambitious miner, the progressive mining man, advertisers who bought space in COAL AGE knew their advertisements would be read as long as COAL AGE made good on its promises and so held the men it was built to appeal to and hold.

You are that progressive mining man, that ambitious miner. COAL AGE advertisements are for you, and when you read them and act on them, *you serve yourself.*

COAL AGE

Vol. 1 NEW YORK, NOVEMBER 4, 1911 No. 4

THIS is no fable designed to convey a moral; nor is it fiction built from imagination; it is a brief recital of experience common to many coal men.

———o———

One evening, several years ago, I was sitting in my office poring over a map and figuring some way around a fault that had cut off our best coal. Of a sudden, the mine on the hill, 1000 ft. above, exploded. I jumped to the door; the mouth of the main entry was belching fire; the valley lighted up as though it was day, and the air filled with timbers, cars and coal.

Only the night shift was underground, but at such a time we don't figure whether half-a-dozen or half-a-thousand lives are at stake.

Soon the fan was running, a rescue party formed and messages despatched for help and material.

The mine was an open-light operation; in fact only a few safety lamps were available in the camp. Rescue apparatus had not been introduced in America, and the first-aid movement was only in its inception, so that no trained corps were available.

Men never worked harder than the fearless fellows on that rescue party. Each individual was striving in a common cause—the saving of human life. There was no thought of recompense, and less of personal danger. Even wives and children were momentarily forgotten.

For six hours the party worked with frantic haste, realizing each moment was precious. Ears were strained for the slightest sound of life on ahead. Brattice after brattice was built, and the air was pulling strong up to the point the rescuers had reached. When—

Without warning, there was a second explosion, and of all the volunteers who went underground that night only three live to tell.

Since then, I have been present at a number of mine disasters and have looked on the bodies of many victims, but the faces of the men who served on this, my first rescue party, are ever vivid in memory.

———o———

Regret is futile, and mistakes are but lessons in wisdom. The past cannot be changed; only the future is in our control. Still I often think how differently I would act now, and how unnecessary was the sacrifice of all those lives.

There would be no open lights in that party, no matter how strong the air-current, if the chance to serve came again tonight. Pell-mell haste would be forbidden, and I would fell or shoot the first man to disobey an order or venture ahead on his own responsibility—better one man die than a dozen.

It would be easy to fill a page telling what course I would now pursue; however, this is to be a reminder rather than a sermon.

You know that most of our misfortunes in the mines result from a disregard of common knowledge, a violation of elementary principles, or, last and greatest, a hasty and mistaken show of bravery.

We are fully aware of the dangers to be encountered, and many understand the technology of gas and dust explosions. What we lack most is courage—not courage to go underground and face the dangers, but a more heroic type that refuses exposure to needless danger.

Courage without wisdom is mere boldness, and this sort defeats itself. Be sure of the men you are with; your party as a whole is only as safe as the most ignorant and most careless member. *In many instances, more men have perished in the attempted rescue than were killed in the initial explosion.*

Work and Purposes of Mining Bureau

The Federal Bureau of Mines, with Joseph A. Holmes as its director, on July 1, rounded out the first fiscal year of its existence. It has been a year fraught with effective organization, and big accomplishments. It may seem hardly fair to say the latter, for it must be remembered that the Bureau of Mines is the successor to the Technologic branch of the United States Geological Survey, and that its work was but a continuation and enlargement of the problems outlined several years ago by Doctor Holmes as head of this branch. The real work of the Bureau of Mines has therefore been going on since 1907 which will be remembered as the darkest year in the history of American coal mining, the aggregate number of deaths in accidents reaching a higher total than ever before.

Loss of Life in the Coal Mines

The most important problem before the Bureau of Mines is an attempt to reduce the number of deaths in the mines and it is gratifying to note that in the last three years for which statistics are obtainable, there has been a decrease in the number of fatalities amounting to 25 per cent. In the year 1907, three thousand one hundred and twenty-five miners lost their lives, or 4.86 in every 1000 employed. In 1909, the last year for which there are official statistics, the number of deaths was 2412 or 3.62 men in every 1000 employed.

The record of the three years is as follows:

Year	Killed	Injured	Death Rate per 1,000 Employed
1907	3,127	5,316	4.86
1908	2,451	6,772	3.60
1909	2,412	7,979	3.62

As the year 1907 was the greatest in the history of American coal mining in the amount of tonnage and the number of men employed, it has been argued that the reduction in the number of deaths in the ensuing years may not be taken as an accurate criterion of improvement in conditions. However, the number of tons of coal mined for each life lost in the three years shows conclusively the betterment of conditions. The statistics are as follows:

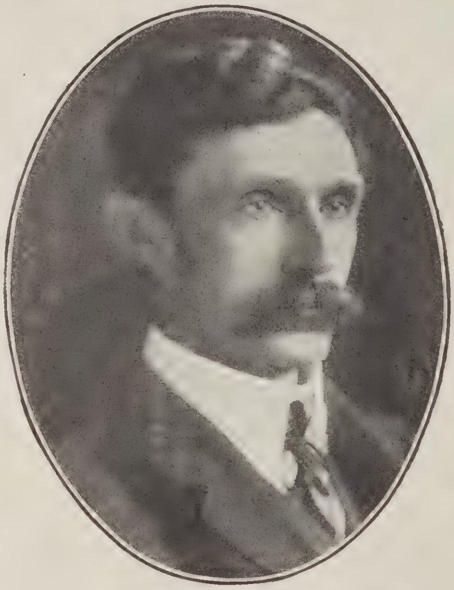
1907	145,471 tons
1908	167,545 tons
1909	186,567 tons

Still another way of showing the improvement is by the number of lives lost for each million tons of coal mined during 1907, 1908 and 1909:

The Bureau of Mines has made many important original investigations. Not less important has been its educative work, resulting in many economic and safety developments. It has been of much practical assistance in mine explosions.

1907	6.80
1908	5.96
1909	5.36

The Bureau of Mines does not pretend to take all the credit for this reduction in the number of deaths in the mines. The agitation which followed the four explosions in December, 1907, in which more than 700 men were killed, undoubtedly brought forth a new sense of responsibility upon the part of both the operator and the miner. This led to a more serious realization of the dangers that lurk underground and a desire to find the remedy.



J. A. Holmes, Director of Bureau of Mines

Explosibility of Coal Dust

The Bureau of Mines has performed no service better for the country than drawing attention to the fact, little credited at that time, that coal dust in a bituminous mine is more dangerous and more deadly to the miner than gas. Heretofore it had been believed that firedamp was the greatest menace of the mines and but little effort was made to prevent the accumulation of coal dust. Although many miners and mine operators believed the dust of bituminous coal would ignite from an explosion of firedamp, nearly all of them contended that the dust in a mine free from gas would not explode. Consequently in many mines where no firedamp would ordinarily be detected, miners paid little attention to coal dust, and in some of these mines terrible explosions have taken place.

The confirmatory demonstration to the American public by the Bureau of Mines that coal dust was the greatest menace to the mines called attention to another important phase of the problem, known indeed before, but none too generally. The most serious disasters had occurred more frequently in bituminous mines in the late fall and winter than during late spring and summer. The experts directed attention to the fact that the mines were drier in the winter than in the summer and therefore the coal dust was more liable to explode. They explained that cold air holds less moisture than warm air. The cold air, entering the mine to ventilate it, takes up the natural warmth of the mine, is raised in temperature to such a degree that it absorbs the moisture and passes out carrying the moisture with it. This process continues until the mine, including the coal dust, is perfectly dry. Such a condition makes a mine ripe for an explosion.

This information was important, because it told the operators and miners when it was necessary to take the greatest precautions.

Remedies for Coal Dust

The Bureau of Mines did not stop with the declaration that dust in bituminous mines was the greatest danger, but set about at once to find remedies. These were promptly given to mine operators and miners, with the result that in many mines, excellent precautions are being taken to prevent such explosions.

The first recommendation was the use of such explosives as the Bureau of Mines declared on examination to be reasonably safe in mines where either gas or dust is found. The use of black powder in dangerous mines was strongly opposed, as in every instance where black powder was used in the experiments, it exploded the gas or coal dust. Operators were requested to use only short flame explosives in dangerous mines.

The experts also urged that all dusty mines be kept wet, either by spraying water, or turning exhaust steam into the ventilating current, keeping the air

in the mine humid. In a bulletin published and sent to miners and operators, the experts stated: "There are two ways of keeping coal dust from being dangerous. One is to wet it; the other is to mix or cover it with rock or shale dust, clay or sand. If the coal dust is wet enough it will not ignite; if there is enough unburnable dust mixed with it, a flame will not spread."

Many mine owners adopted these precautions and State mine inspectors have insisted upon their use in mines they deemed dangerous. State Mine Inspector Laing, of West Virginia, in a recent statement declared that as a result of using the explosives recommended by the Bureau of Mines and the wetting of the mines in his State, there had not been a life lost from gas or coal-dust explosions in 17 months. This record has never before been equaled in the coal-mining history of his State.

Experimental Coal Mine

One of the real achievements of the Bureau of Mines has been the establishment of an experimental mine at Bruceton, Penn., 12 miles from Pittsburg, Penn. Other coal-mining countries have been talking of the necessity for such a mine for some years, but it remained for the United States to take this important step first.

The experimental mine was found to be an urgent necessity if the tests into the explosibility of coal dust and gas were to be carried to a successful conclusion. It was demonstrated in the experimental tube or gallery that coal dust would explode, but there were serious limitations placed upon the tests owing to the fear that the gallery would not stand the force of big explosions. Under the strain of certain tests at European stations, the galleries were destroyed.

Many who witnessed the coal-dust experiments at the Pittsburg station were anxious to have them made on a larger scale than is possible in experimental galleries and also to have the tests made under actual mining conditions. It is reasoned that when the exact conditions under which explosions take place are understood, tests of various preventative measures can be undertaken with some degree of precision. The experimental mine, which will soon be ready for tests, will be opened for a while in the same manner as many other mines, with all the bad practices that are found in mining—just to see what the results will be. The experts of the bureau have defined a number of these bad practices and they intend to prove in this mine that they are bad. All the remedies proposed by the engineers for removing the dangers of coal-dust explosions will be tried in the mine, in order that their efficiency may be demonstrated beyond all dispute.

A secondary purpose of the experimental mine will be a study of the explosives that have been placed on the permissible list for use in gaseous and dusty mines—testing them under actual working conditions in coal. Still another purpose will be the testing under mine conditions of gasolene motors to determine the safety of the apparatus in actual use. It is probable that many devices will be tested under actual service, and also tests made of the insulation of wiring. It is believed that the miners and operators will place more faith in the tests conducted in a mine under mining conditions than in the experimental gallery. Some have maintained that what happens in the experimental gallery does not happen in a mine.

Raising Man from Electric Wire

The Testing of Explosives

It should be explained here that the Bureau of Mines has a completely equipped experiment station at Pittsburg, Penn., situated on the Arsenal grounds, Fortieth and Butler streets. Here the various explosives used in coal mining are tested to determine which are the safest to use in dangerous mines.

When the Government took up the investigation of explosives, it found such variation in the strength of the explosives and such reckless use of them in many of the mining fields that it might be said the miner took his life in his hands almost every time he touched off a fuse.

Not only were the explosives extremely dangerous in themselves through their variability, but they were oftentimes used in such large quantities as to preclude

the possibility of safety. The mortality statistics prove this contention. Fifty per cent. of all the fatal accidents and 39 per cent. of the non fatal accidents are the result of falls of roof and coal. In European countries the number of accidents from this cause is much less, which leads to the conclusion that in the United States the very great disturbing and jarring effect which the discharge of large amounts of explosives in a mine exerts is one of the most important factors which bring about the fall of roof and coal. It is believed that although the actual fall of rock or coal may not occur at the time of firing the charge, the heavy shot weakens the walls and roof, so that months after, without warning, it falls.

With such conditions to contend with, the Government proceeded to standardize explosives and to find out just what types were comparatively safe for use in mines that contained gas or coal dust. Manufacturers of explosives were invited to send in their explosives to be tested and they responded readily. The tests were conducted in the great steel cylinder, 100 ft. long and 6 ft. in diameter, the explosives being fired by electricity into gas or coal dust, or both gas and coal dust. Those explosives that did not ignite the gas or coal dust, after repeated trials, were passed upon as "Permissible Explosives" and recommended to the various State mining bureaus, coal-mine owners and miners, as being reasonably safe.

The tests brought out conclusively that it was exceedingly dangerous to use black powder in dangerous coal mines. In repeated tests the black powder never failed to ignite the gas or coal dust. This information was given to the operators and miners and there was the immediate abandonment of the use of black powder by many operators. It was shown to both miners and operators that with equal quantities of permissible explosives and black powder, the flame of the black powder is more than three times as long and has a duration of from 3000 to more than 4000 times that of one of the permissible explosives, and the rate of explosion is similarly slower. The length of flame is an important consideration in the relative safety of a powder, the longer flame and the flame of longer duration having just so much more opportunity to ignite the coal dust or gas.

As a result of the Government's efforts, the use of black powder in dangerous mines has been prohibited in certain States and in other States operators are using the permissible explosives voluntarily. In 1908, the coal mines used 2,000,000 lb. of short-flame explosives; in 1910 they used almost 12,000,000 lb. which is more than is now being used in Great Britain after many more years of experience. Perhaps nothing so much as these figures shows the splendid coöperation between the operators and this bureau. The continued use of the permissible explosives will have an increasingly good effect as time passes.

Mine-rescue Work

Since the bureau was organized, it has placed seven fully equipped rescue cars in the principal coalfields of the country. One car has headquarters at Wilkes-Barre, Penn., a second at Trinidad, Colo., the third at Evansville, Ind., the fourth at Rock Springs, Wyo., the fifth at Billings, Mont., the sixth at Huntington, W. Va., and the seventh at Pittsburg, Penn. In addition, the bureau maintains rescue stations at Pittsburg, Penn., Knoxville, Tenn.; Birmingham, Ala.; Urbana, Ill.; McAlester, Okla.; and Seattle, Washington.

Each rescue car is in the immediate charge of a mining engineer, who has with him a miner trained in rescue work and another trained in first-aid-to-the-injured methods. In time of disaster, the first miner, who is the foreman of the car, has charge of all rescue work. Each station is in charge of a foreman who is a practical miner, trained in rescue work. The stations and cars have complete outfits of oxygen helmets, which permit breathing for two hours in deadly atmospheres; oxygen reviving apparatus used in bringing asphyxiated miners back to consciousness; a collapsible steel cage to take the place of one shattered by an explosion; a portable telephone for use in the mine; safety lamps, etc.

Within the last twelve months 5000 miners throughout the country have been thoroughly trained in rescue work and many have been given certificates of efficiency. These men will volunteer their services whenever there is a disaster.

Each Bureau of Mines rescue car has a specified territory over which it travels, visiting the mining camps. At each stopping place, demonstrations in the use of the oxygen helmet are given, also lessons in first aid to the injured. In the evening, the mining engineer gives an illustrated lecture to the miners on greater safety in mining. Thousands of miners have attended these lectures in the last few months and have gone back to their hazardous work with a keener sense of its dangers, a desire to be more careful and to live up to the precepts of good mining. All of this must necessarily have a salutary effect.

Interior of Rescue Room at the Pittsburg Station

First Aid to the Injured

More than 5000 men are injured in the coal mines of the United States every twelve months. Some recover sufficiently to return to work, but several regiments of men are so maimed and crippled each year as to be useless to themselves and burdens to their families. Many of the injured men who are taken from the mine die later, perhaps within a few months. In quite a few instances, the death of these men or their crippling for life is due to the fact that they did not receive intelligent emergency treatment at the time of the accident.

It is to better this condition of affairs that the Bureau of Mines carries on each car, a practical miner trained in first-

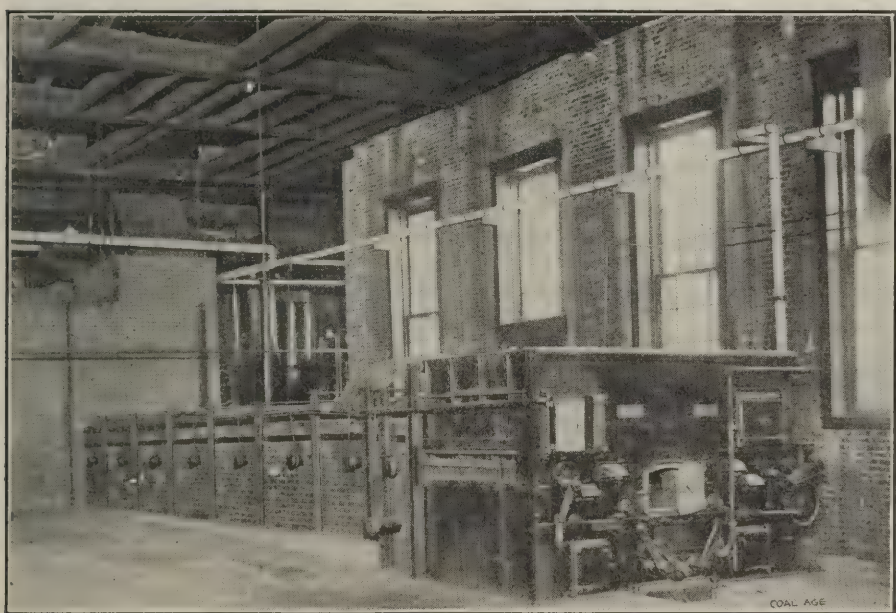
aid-to-the-injured work. This employee, while not engaged in actual rescue work, teaches the miners how to care for an injured comrade. Simple lessons in bandaging wounds and providing splints for broken legs are given at every mining camp visited. The miners are taking special interest in this feature of the work and it too promises to have an important bearing on the reduction of the death rate.

When the Government started to demonstrate the need for rescue work in the coalfields, rescue apparatus such as the oxygen helmet, which permits artificial breathing in poisonous atmospheres, and oxygen reviving apparatus to bring asphyxiated miners back to consciousness were practically unknown in the United States. Today, there are more than 300 oxygen helmets throughout the country, some belonging to the Bureau of Mines, others to State mining bureaus and still others to various coal companies. In the last two years, between 30 and 40 coal companies have purchased full rescue equipments and have crews thoroughly trained in rescue work. All of this is the result of the work of the Bureau of Mines. The Frick Coke Company, employing 30,000 men, has established a complete rescue station near Connellsville, Pennsylvania.

The Consolidation Coal Company, another big concern, has established a rescue station at Fairmont, West Virginia.

A third station has been erected at the Marianna mine in Pennsylvania by the Pittsburg-Buffalo Coal Company. Altogether it is believed 50 operators have established stations. In addition, the States of Illinois and Kentucky have established rescue stations and Illinois has mine rescue cars at its established centers. Ohio is about to equip a number of rescue stations. There are also a number of rescue cars owned and operated by the coal companies, one in the anthracite region, one in Colorado, the property of the Colorado Fuel and Iron Company, and one in Tennessee, the property of the Tennessee Coal and Iron Company.

The various rescue corps of the bureau have done valiant service at a number of disasters. Altogether it is estimated they have been instrumental in saving more than 25 lives during the year. This is the direct result. It is impossible to tell how many lives have been saved by the miners who have been trained in efficient rescue work by the Federal rescuers, and, after all, that is the real purpose of the Bureau of Mines rescue service. In many instances it is not to be expected that the rescue cars can arrive at the scene of a disaster in time to be of service, on account of the distance to be traveled, but the miners can be trained to conduct the rescue work themselves.



Murphy Smokeless Furnace Having Long Combustion Chamber

The Bureau of Mines and the Miner

In addition to carrying the educational work to the miners at the mines by means of the rescue cars and substations, the bureau has recently begun the publication of a series of circulars written in plain, nontechnical English for the benefit of the miners themselves. Two circulars have already been issued, one describing the permissible explosives and how they should be used, and another explaining the dangers of coal-dust explosions and how to avoid them. These circulars are now in the hands of several thousand mine superintendents, firebosses and miners and they are being sent out each day to those who apply for them. That these circulars are deeply appreciated by the miners is attested by the hundreds of grateful letters that have been received by the bureau within the last few months, mostly from the miners themselves, but many from operators and owners.

The bureau is also publishing bulletins, for the benefit of the operators, mining engineers and superintendents. These publications are of a more technical nature. They, too, are in great demand.

The increasing requests for all the publications of the Bureau of Mines are a true index of the interest that is being taken in the work and also a potent evidence that conditions are improving.

The Fuel Investigations

The investigation of the fuel resources of the United States is one of the serious and important problems of the Bureau of Mines. No nation can be great and prosperous without an abundant supply of fuel. Some countries have awakened to this fact too late, but the United States, with its usual foresight, has begun important investigations in plenty of time to conserve the supply. But the investigations into the waste in the mining of coal and the waste in the consumption of coal have not begun too soon. The fuel resources of this country are being used and wasted at a tremendous rate. The consumption of coal in the United States has doubled with every decade since mining began. Without a decided lessening of the present rate of coal consumption, either through more efficient use of this fuel or the extensive development of substitutes for it, the middle of the next century will find the nation's supply of easily workable coal so largely depleted as to bring serious hardships and a curtailment of manufacturing industries. The waste of the fuel resources is perhaps more serious than other resources, for the timber when gone can be replenished, the fertility of the soil can be restored, but when coal is gone, it is gone forever.

The total production of coal in 1909, the last year for which official figures are obtainable, was 460,000,000 short tons.

Investigations into the waste of coal in mining have shown the enormous extent of this waste, aggregating probably 200,000,000 tons yearly, of which at least one-half might be saved.

Waste of Coal in Power Stations

No accurate estimate can be made as to the total unnecessary losses in connection with the use of coal for different purposes, but lines of urgently needed investigation and inquiry are indicated by the facts that in the vast majority of the power plants of the country less than 10 per cent. of the heat units in the coal are converted into actual work.

From the 40,000,000 tons of coal which are converted into coke each year, by-products are wasted, which, if completely

saved, would have an aggregate annual value of more than the coke itself. This would include sulphate, 2,400,000 tons, sufficient to fertilize our farms, creosote for the preservation of our timber, and pitch enough for briquetting our slack coals, roofing our houses and repairing some of our roads.

It is of the utmost importance to the nation as a whole that our fuel supplies be used without unnecessary waste and with the highest obtainable efficiency, in order that it may decrease rather than increase the cost of power, heat and light to the American people, in spite of the necessary future increase in the cost of mining operations resulting from sinking deeper shafts and taking coal from thinner seams. These are the reasons for the fuel investigations of the Bureau of Mines.

The investigations which are now being conducted at the Pittsburg plant of the Bureau of Mines are being directed toward the decrease of the great waste, not only in the mining but chiefly in the utilization of the coal which the United States owns or purchases for its use. This is being accomplished by testing coals under various conditions, in various types of boiler furnaces, in pressure and suction gas producers supplying the gas for the operation of gas engines, and by making the coal into briquets and testing their efficiency in various methods of combustion. The results so far indicate that the U. S. Government, which purchases $10,000,000 worth of coal each year, and the public who buy nearly $2,000,000,000 worth, may ultimately save from 5 to 10 per cent. on their fuel bills as a result of these investigations. If the economy reached but 5 per cent this would mean a saving of $500,000 to the Government each year and $100,000,000 to the public.

Purchase of Coal on Specifications

As a result of the plan perfected several years ago by the Technologic Branch of the Geological Survey and being carried along by the Bureau of Mines, there has been a wide awakening upon the part of the large consumers of coal and the public generally as to the best method of purchasing coal.

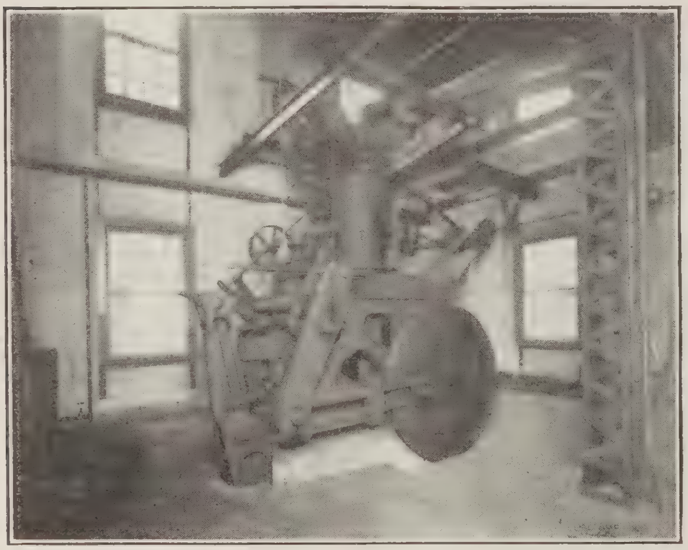
In the past everyone bought coal on the statement of the dealer or the reputation of the coal without asking anything in particular about the heating value or the amount of impurities in it. Now the Government and many of the large consumers are buying their fuel supplies on specifications which fix the amount of ash and moisture in the coal. Under these specifications, premiums are paid for coal better than the standard and penalties are demanded for coal below the standard. Under this system, the Government and big manufacturing establishments have been getting more nearly what they have been paying for and paying for what they get. The system is not only fair to the purchaser of coal but also to the seller, for if the latter has a high grade of coal he gets full value for it. The fuel bill of the Government now aggregates about $10,000,000 yearly, the saving on which, through securing coal containing less ash, alone amounts to nearly $200,000.

As a result of the example of the Bureau of Mines, many large corporations throughout the country are now buying their fuels on specifications. This plan has met with such high favor that fuel-engineering companies which test coals are found in practically all the large cities of the country.

The Gas Producer and Gas Engine

When the Technologic Branch of the Geological Survey began its investigations to increase the efficiency with which fuels are used, it had installed at its plant a gas producer and a gas engine of 250 h.p. The gas producer and engine were hardly known in this country at the time, but experiments in Europe had indicated the ability of the producer to turn coal into gas at little cost and to produce power through the gas engine economically.

The tests by the Technologic Branch and the Bureau of Mines have not only demonstrated that the gas producer and engine are cheap producers of power but have also shown that many fuels of such low grade as to be worthless for steam-power purposes may be economically converted into producer gas and may thus generate sufficient power to render them of high commercial value. Coals containing as much as 45 per cent. of ash, and lignites and peat high in moisture have been successfully converted into producer gas, which has been used in operating gas engines. The tremendous saving of the fuel resources of the country through the utilization of these low-grade fuels can be readily seen.



English Briquetting Machine

Gas Producer

Coal Doubles Its Service in a Producer

It has been estimated that in each test there was developed from the coal in the gas-producer plant an average of 2½ times the power which would have been developed if used in the ordinary steam-boiler plant, and that these relative efficiencies will probably hold good for the average plant of moderate power capacity, though this ratio may be greatly reduced for large steam plants of modern type.

It was found that the low-grade lignites of North Dakota developed as much power when converted into producer gas as did the best West Virginia bituminous coals when used under the steam boiler. In this way, lignite beds underlying from

20,000,000 to 30,000,000 acres of public lands, supposed to have little or no commercial value, are shown to have a large value for power development. This is of importance to the West and makes possible a great industrial development there. As a result of the investigations of the Technologic Branch of the Geological Survey and the Bureau of Mines, many large gas-producer plants have been installed throughout the United States.

The Briquetting of Coal

Another important feature of the work of the Bureau of Mines in conserving the coal supply, is the manufacture of briquets. These are composed of waste bituminous or anthracite coal mixed with 6 to 7 per cent. of gas pitch, the whole pressed into cakes or briquets by powerful machinery. Briquets have been used in foreign countries for many years with much success.

Briquets, in addition to affording a means of utilizing the waste coal, have a number of advantages over coal. They value and thus reduce the cost of transportation.

The Bureau of Mines has just completed a series of briquetting tests using lignite from California, Texas and North Dakota, that promise much to the people of the West. The lignite from these States, which is a form of coal, has been of little value because it cannot be transported far from the place where it is mined. The lignite, shortly after mining, slacks and crumbles into dust. It is also difficult to burn near the mines because of the great amount of moisture it contains, sometimes as much as 30 and 40 per cent. The Bureau of Mines has succeeded in briquetting this lignite without the use of a binding material and at a cost that makes it commercially possible. Some time ago, the bureau in a series of experiments at the Reclamation Service pumping plant at Williston, North Dakota, demonstrated that the raw lignite could be satisfactorily burned under boilers, by turning it into gas. The results of these experiments mean an adequate fuel supply for the people of has not only given its counsel as to the best methods of carrying on a campaign against this great nuisance, but has also demonstrated to those interested that coal can be burned without objectionable smoke. Its plant at Pittsburg is a model for the entire country in regard to the absence of smoke and its experts are always willing to explain how this is accomplished.

The investigations into smoke abatement have indicated clearly that each type of coal may be burned practically without smoke in some type of furnace or with some arrangement of mechanical stoker, draft, etc. The elimination of smoke means more perfect combustion of fuel, and consequently less waste and higher efficiency.

The Chemical Analysis of Coal

Chemistry is assisting the fuel experts to determine the characteristics and the comparative value of coals throughout the country. The primary purpose of the chemical analyses made is to give the Government, and the Navy in particular,

Gas and Dust Gallery No. 1, Bureau of Mines

hold together until almost completely consumed, which gives the air a chance to get between them, making the combustion more perfect and their burning under favorable conditions almost smokeless. It has been demonstrated that they produce a hotter fire than coal because of the added fuel value of the pitch.

The tests with reference to the combustion of briquetted coal have demonstrated conclusively that by this means many low-grade bituminous coals and lignites may have their commercial value increased by an amount sufficient to more than cover the increased cost of manufacture.

These tests have also shown that the highest-grade bituminous coals can be burned in locomotives with greatly increased efficiency and capacity, and with less smoke than the same coal unbriquetted. They have shown that the same locomotive may, with the same fuel consumption of briquets as with raw coal, very materially increase its hauling the Western States, where they had practically none before. The importance of these results is even further magnified when it is considered that the lignite fields are situated at great distances from the bituminous fields.

Steaming Tests of Coal

The tests of different coals under steam boilers have also shown the possibility of increasing the general efficiency of hand-fired steam boilers from 10 to 15 per cent. over ordinary results, and if this saving could be made in the great number of hand-fired boilers now being operated in all parts of the United States, it would result in a large saving in the fuel bill of the country and a resultant conservation of the fuel resources.

The Smoke Problem

The Bureau of Mines has wielded a large influence in the abatement of smoke in the large cities of the country. It exact information regarding the various coals purchased, no matter from what field in the United States. If a naval vessel coals at Boston, these tests will enable its engineer to select his fuel intelligently and to know what it is capable of doing. This information, it is conceded, would be of extreme value in time of war.

The analyses made are of great service not only to the men who do the Government's work, but to engineers throughout the country; and under the stimulus of work of this kind the question of fuel efficiency is receiving attention in many parts of the country. Many power plants in the United States are now buying fuel on definite specifications and have obtained increased efficiency as a result of the Government's investigations.

These chemical analyses of samples of coal from all the coalfields of the United States will aid manufacturers, wherever situated, to save money in the purchase of fuel, for they will enable them to

learn where they can buy the coal that is best suited to their purposes.

The results of the chemical analyses of coal will be published by the Bureau within the next few months. To the engineers of the country and the consumers of coal it promises to be one of the most valuable and most important bulletins ever published by the Government.

Some of the Results

The Bureau of Mines, through the influence of its fuel investigations and the publication of the results, has indirectly been responsible for economies involving millions of dollars and the consequent conservation of the fuel supply of the United States.

The bureau does not by any means claim sole credit for a number of the big improvements in the use of fuels, for many individuals were at work on some of these problems before the Government took up the work, but it does believe that its general campaign of educational work and the practical results accomplished have been responsible for a quick realization of many big economic projects that might otherwise still be in the future.

Two of the most notable of these projects may be briefly described here. At the St. Louis World's exposition, the United States Steel Corporation exhibited a 5000-h.p. steam engine as the marvel of the age. At the same exposition, the Government began its investigation of the possibilities of the gas engine operating on producer gas. Today, the Steel Corporation is operating gas engines with an aggregate capacity of a quarter of a million horsepower, using the waste gases from the blast furnaces as fuel. These gases formerly went into the air, polluting it and making life difficult in the vicinity of the great furnaces. The Government has not operated its gas engine on furnace gases, but it has shown the possibilities of the gas engine as a producer of power. The power equivalent of the gas engines of the United States Steel Corporation operating on waste gases, amounts to more than 1,000,000 tons of coal yearly.

The Technologic Branch of the Survey and the Bureau of Mines have preached the use of low-grade fuels and have practised what they preached by burning practically waste fuel in the furnaces at the testing station.

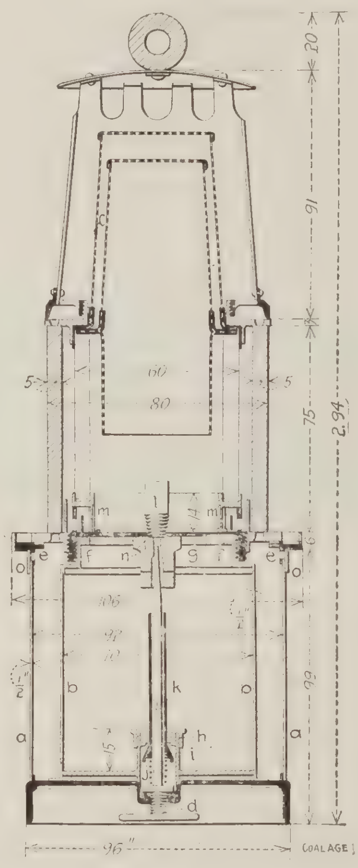
The Lehigh Coal and Navigation Company is considering the erection of a great central power plant at its mines in Carbon county, Penn. This plant, if constructed, will cost $3,000,000 and later extensions may be made involving a further expenditure of $7,000,000.

The fuel to operate this plant will come from a mountain of anthracite waste, (culm), the dump pile containing 10,000,000 tons of coal of such low grade that it cannot stand the cost of transportation. This great power plant will transform its power into electricity which will be transmitted for miles around, supplying factories, railways, shops and homes with light, heat and power.

Now that one company has started making use of the waste, or low-grade fuels, which has been urged by the Bureau of Mines, it will not be long before other plants of like nature are found at the bituminous mines of the middle West and at the lignite mines of the far West.

Acetylene Safety Lamp

At the conclusion of a paper in *Bulletin* de la Société Industrielle du Nord de la France, No. 165, in which a number of different types of safety lamps



Details of New Safety Lamp

designed for burning acetylene are described and illustrated, E. Didier dwells particularly on the construction of a lamp of this nature designed by A. Tombelaine.

The three essentials of the lamp are a cylindrical reservoir *a* for water; an interior receptacle *b*, for carbide; and the combustion chamber *c*. The water reservoir *a*, has several small holes *e*, at its upper edge, and a hole at the center of the bottom, threaded to receive the thumbscrew *d*. The carbide receptacle has a threaded ring around its top, by means of which it is tightly closed by the cover *g*, and at its bottom a valve chamber containing a felt washer *h*, a conical valve *i*, held in position by the spiral spring *j*. The pin *k*, which is a continuation of the thumb screw *d*, passes up through the valve rod, and serves to regulate the escape of acetylene through the burner *l*. The combustion chamber consists of a thick glass ring, two wire-gauze mantles, and a sheet-metal jacket, identical with the usual types of benzine safety lamps, except that the inner gauze extends downward below the outer. Air is allowed to enter through openings just underneath the glass cylinder, the orifices being so arranged with baffles and protected with gauze as to prevent a strong breeze from blowing against the flame. The lamp is locked by a fusible plug.

Method of Operation

In operation, carbide is placed in the inner receptacle, which is then screwed into place, and the bottom of the lamp immersed in water until it flows through the holes *e*, and fills the water reservoir. It then reaches the carbide chamber through the passage *n*, and the valve *i*. The amount of flow is regulated by turning the thumb-screw *d*. The object of the downward projecting gauze mantle is to prevent breakage of the glass if the flame should momentarily increase to unusual size.

In order to be able to use the lamp for detecting firedamp, the size of the flame can be much diminished by turning the thumb-screw *d*. This has the result, first, of cutting off the supply of water, and then of reducing the flow of gas through the needle valve *n*. Without the second provision, it would be necessary to wait several minutes for the generation of gas to cease after closing the water valve. Any surplus gas, after closing the needle valve, can return through the water reservoir and escape into the air. In ordinary use, the water and gas valves require but little adjustment.

The illuminating power of this lamp is about 6 c.-p., or five times that of an ordinary benzine lamp. Empty, it weighs 1.5 kg. The normal flame will last for 11 hours with a consumption of 100 g. of carbide and 150 g. of water.

The Cokedale, Colo., explosion illustrates the necessity of a mixed rescue corps, that is, a corps composed of men performing different duties in the mines. At Cokedale the rescue corps was composed entirely of shot firers and as the accident occurred at night while they were all on duty, the entire corps was either killed or severely injured, thus leaving no one trained in life saving to aid the miners and other employees trapped in the mine by the explosion.

American Mining Congress Meeting

Special Correspondence

The attention of the convention was largely directed to a solution of the present deplorable conditions surrounding the coal industry. It was the consensus of opinion among delegates that the Government should permit a better control of production and a fair regulation of coal prices.

The annual meeting of the American Mining Congress was held at the La Salle hotel in Chicago, Oct. 24 to 28, inclusive. The convention was well attended and the papers presented were of considerable interest, especially to coal men. President Taft addressed the Congress Saturday morning, Oct. 28, devoting considerable attention to the Alaskan coal-lands question. Secretary of the Interior Walter L. Fisher talked to the delegates Friday evening, Oct. 27, also occupying his time with a discussion of the coal-lands question in Alaska.

President Taft touched lightly upon the Ballinger incident by deprecating the unnecessary attribution of evil motives to those who directed the affairs in Alaska in the past, and said Secretary Fisher would earn his undying personal gratitude, as well as cause him to rejoice as an American citizen, if he put Alaska once more in untroubled waters, and in the way to a reasonable development.

The President also referred to the excellent work being accomplished by the Bureau of Mines, and paid a pretty compliment to the energy and effectiveness of Doctor Holmes, the present director.

Turning from the field of agriculture to the mining interests of the nation, Mr. Taft continued:

"So it is with respect to the mining industry; that, next to the agricultural industry, is perhaps the most important we have. It spreads over all space. It divides itself into so many different varieties and is so widespread that no one State can give to the research, investigations and general publication of results, the time, money and attention, and the number of people required, in order that we should make progress there. This is especially true with reference to the saving of the lives of miners engaged in this industry, and I am glad to note that Congress has passed a law creating a mining bureau."

President Taft then referred to the fact that in 1862 when the Homestead law was passed, the present Department of Agriculture was established. It was called a department, but the man at the head of it was not a cabinet minister, and he did not become so until many years later. The President's evident idea was to call attention to the parallelism between the establishment of the Department of Agriculture and the present Bureau of Mines, and to indicate that the growth of the agricultural bureau is likely to be repeated in the case of the mining bureau.

During the convention, interesting papers dealing with various phases of coal mining were presented by A. J. Moorshead, president of the Madison Coal Corporation, St. Louis, Mo.; Carl Scholz, president of the Consolidated Indiana Coal Company, Chicago, Ill.; D. W. Kuhn, president of the Pittsburg-Westmoreland Coal Company, Pittsburg, Penn.; G. W. Traer, Chicago, Ill., and Walter Williams, president of the Hart-Williams Coal Company. Practically all of these papers contained a plea that the Government should so modify the Sherman act that coal men might be permitted in some way, to regulate coal production and prices.

Various plans for controlling production and equalizing prices of coal were suggested: Carl Scholz called attention to the operations of the Westphalia Selling Syndicate in Germany, citing the history of this organization as one that might be profitably studied by the American people. Mr. Scholz said, "The same difficulties which now confront the coal operators of the United States were, in the early stages, experienced by mine owners in the Westphalia district in Germany. In fact, during 1870, a crisis was reached and disaster was only avoided when the German-France war brought a decided, but short-lived, relief.

A Lesson to American Operators

"The lesson to the coal operators of the United States is that Germany has faced and solved problems similar in character to those with which we are struggling." It was shown by Mr. Scholz that the sale of mining products can be handled more advantageously through an entirely separate organization managed by a firm of salesmen under the direction of the owners. This is the plan on which the Westphalia Coal Syndicate operates. The plan of the German company is buying and selling coal and coke, and acquiring mining fields and shares in mining companies. The capital is $600,000, divided into 8000 bonds of $75 each. This capitalization is based on 80,000,000 tons of production. Each member of the syndicate must acquire one bond for each 10,000 tons of annual output.

The management is intrusted to a board of two or more members elected from the directors, and twelve members, three of whom are changed each year. The managers are elected at the annual meeting of the bondholders. The tonnage allotted to each company is fixed by a commission of eight members. The syndicate buys and pays for all the coal covered by allotment. None of the product can be sold by any producer except through the syndicate. A mining company must furnish the quantities agreed to and the syndicate must market it. The mines owned by the German government have, since 1905, sold their product in competition with the syndicate. It is believed they will, later on, join the syndicate.

The chief advantage claimed for the Westphalia plan is the elimination of unnecessary and suicidal competition, and the result has been to place the coal industry in Germany on a basis which enables the operators to produce their tonnage at a reasonable profit; as a consequence, they are able to pay the miners a fair wage and furnish better protection against injury than was possible under conditions that previously existed.

An Increased Profit

The increased profit that has resulted to German coal operators since the organization of the Westphalia Selling Syndicate has warranted the better equipping of the mines with modern machinery and appliances. The advantage to the coal consumer has been the elimination of fluctuations in price by the depression of low figures in a time of surplus, and by rises to higher figures during a time of shortage. Under this plan, the consumers receive a more uniform price and the large consumer does not get a low price at the expense of the small buyer, who may be compelled to pay exorbitant figures.

The syndicate has, through the establishment of agencies, and arrangement for shipping facilities, made possible an efficiency in the marketing of coal, which cannot be reached by the individual producer.

Mr. Scholz concluded his remarks by saying: "Indicative and impressive is the inscription on the syndicate-building entrance, reading, 'Unity Makes Strength.' "

The remaining papers presented before the Mining Congress, and that are of interest to coal-mining people, will be published in the next issue of Coal Age.

National Mine Safety Demonstration

Special Field Correspondence

The Bureau of Mines, inadequately housed at the Pittsburg Arsenal, exhibits the plant where its many important investigations are in progress. Interesting and valuable demonstrations are conducted for the throng of visitors. The Bureau's present work is described and its future aims are outlined.

The national mine-safety demonstration has not failed to measure up fully to the expectations of the most sanguine of its promoters. Nothing is clearer than that there was nothing forced about the expression of interest of all concerned. It was not artificially augmented and fostered by any of the numerous agencies, which were the prime causes of the demonstration. The miners and the corporations are responding with ardor because "security first" is the most pronounced of all present-day mining sentiment.

The morning of Oct. 30 was spent in and around the buildings of the Bureau of Mines in the Arsenal grounds. These buildings were somewhat of a surprise to visitors who saw them for the first time, though it has generally been conceded by those who have viewed them before that they are inadequate for the purpose to which they are devoted. One felt a chill sensation as he piloted Joseph G. S. Hudson, chief of the new explosive section of the Dominion bureau of mines, Ottawa, Can., through the archway by the quaint and dingy quarters occupied by the Arsenal authorities.

These quarters, dating back to the early part of the last century, are built of old-fashioned hand-made brick. They inclose two little grassy squares. Back of the second square, set in a way economical of room, without any attempted grouping, and not facing in front or rear or sides on the lawns to which reference has been made, stand some long shed-like buildings for which the war department has no longer any use. No military force is kept at the Arsenal, the buildings facing on the two squares being used as a hospital and for the storage of quartermaster's supplies. In these inglorious buildings, at the rear, are summed up, structurally speaking, all that, after many years of agitation of congresses and institutes, the mining industry has secured from the Federal Government.

One of the buildings was once a paint shop. None ever rose to any dignity higher than a storehouse, until upon their dingy, somber fronts appeared the pretentious titles, "Bureau of Mines" and "Bureau of Standards." Concurrently, there were placed in two of them narrow passageways with cramped stalls on the right and on the left, in which the bulletins are being prepared which are being so freely quoted at home and abroad, either as the last word on uptodate mining or as lucid expositions of home and foreign researches.

Showing Ballistic Pendulum Immediately after a Powder Test

To revert to Mr. Hudson, one cannot but recall that he is about to erect a \$25,000 building on a lot already owned

by the government of Canada, that his bureau starts with an appropriation of $100,000, and that when that is expended the council of the Dominion expects to spend more.

When the present-day mining interests of Canada are considered and compared with those of the United States, one realizes how far less adequate is the provision of our Federal Government for safety and economic development than is the provision of the government of the Dominion. Nevertheless, Canada today has a population barely equal to the population of the State of Pennsylvania.

A new one-story red-brick shed has recently been erected to house some new experimental apparatus of the Bureau of Standards. It is to be hoped that no new buildings will rise of like kind in such a place, and that a new location, with a less restricted opportunity for development, will be found for one or both of these bureaus, and that when that happy time comes a building will be provided comparable to that erected to take care of the Bureau of Agriculture, or that part of the Bureau of Standards at Washington, D. C.

The Future Aims of the Bureau

The testing of explosives is so completely described under another caption in this same number that there is no need to elaborate on it here. The nature of the present work of the Bureau and the purposes of that work also are given in another place in this article. It is, therefore, opportune to call attention, not so much to present work and present purposes or past achievement, as to the future researches and future aims of the Bureau of Mines.

Research is not peculiar, for like all human activities, the preliminary planning rarely outlines the final resultant work. Questions in their solution involve others, so that ramifying problems spread out in several directions from what at first appears a simple inquiry.

It may be well to quote here the hithertofore unpublished statement of the chief engineer, W. H. Wilson, relative to the inquires the bureau purposes to try to solve. In an address before the Coal Mining Institute of America he declared the intention of the bureau to investigate misfires and their causes, the economic use of explosives in coal and metal mining, the nature of coal dust as exhibited in the several mines of the country, the problems resulting from quarrying practice, methods of tunnel driving in metal mines, the evidences of presence and the nature of mine gases, a comparison of the laws relating to mining in the various States, and throughout the world, problems of sanitation, and suppression of smelter fumes.

But we can readily see that the bureau will eventually enter the field of physics and chemistry, in a basal way, trying to discover what are the preliminary and concomitant actions of the gases in an explosion; what transpires before an explosive gas flames and explodes; what is the real, not the theoretic, reason for high specific heats; why safety lamps are reasonably safe, and other kindred subjects. These unpopular problems of great profoundity may give rise to certain simple, practical rules, which, if observed, may make it possible to avoid explosions.

In fact, no form of knowledge, however erudite and removed from practice, is unlikely to give practical results. The early work on coal-tar products was not

First-aid Miners' Team Bandaging for Face and Neck Wounds

Two-man Event, Showing Judges Observing Speed and Efficiency of Team

A Number of Bituminous First-aid Teams during Rest Interval

Bandaging and Splinting of Man with Broken Arms and Legs

conducted to discover a sweetening substance, to prepare a coloring for dress goods or wine, to provoke a steady action of the organic functions or to relieve headache, but inadvertently it has laid bare all of these. And the public would do well to prevent pressure from being brought to bear on the bureau to be too severely practical, that is, to seek results before causes, or to hunt the place before the road thither.

Many Problems

The action of air currents on lamps of various designs the nature and methods of resistance of immunizers to explosion, the best forms of immunizers, the value of various sprinkling devices and humidifiers, the possible action of electricity and electric arcs on air, the absorption of oxygen by coal, and the slow oxidation of the latter, the peculiar nature of coking coal, causes of fluxing and caking of coals in the furnace, the effect of waste gases from oil and gas engines on the purity of the air currents, the structure of the roof, its action under stress, with all that this includes, the loads on mine timbering and steel work, the corrosion and pollution by mine waters, the best methods of complete extraction of minerals, the more favorable method of using waste gas and byproducts from ovens, the manner in which timbers may be creosoted, the destruction of various types of timber fungi, the best forms of concreting and dampproofing for mines, the prevention of overwinds and falling cages, the determining factors in the direction of an explosion, the distance an explosion will travel over dustless, wet, damp or immunized zones, or in the same direction as an air current, the speeds and pressures during an explosion, the strength of stoppings needed to resist its extension, the temperatures resulting and the means of tracing back an explosion to its primary focus and initiating cause, the possible relations of compression to forceful explosions, the possibility of explosions being caused sometimes by mine concussion, are a few of the subjects which the industry is requiring the bureau to settle, and to which it is likely that the industry will receive no answer for many years.

Unnecessary Duplication of Inquiry

It must be remembered that the Bureau of Mines is almost the only body in the United States which is doing any amount of mining-research work. In England, the work is being divided freely among the colleges and universities, and interesting results are being obtained. But here, apart from the experiments on the strength of packwalling at Lehigh University, and on the causes of spontaneous ignition, still undetermined, at the University of Illinois, almost nothing has been done toward mining-research work, except by this bureau, though not a little was accomplished at one time in ascertaining the causes of heat waste and imperfect combustion in boilers, a field which the Bureau of Mines, in its desire to conserve fuel, regards as a part of its domain.

A Bad Practice—Opening Powder Keg with a Pick

An Illegal Act—Filling a Cartridge without Removing Lamp

It is to be hoped that some effectual means may before long be taken to prevent duplication of experiments in America and abroad. Although some experiments need duplication, if only for a confirmation to our own people that the results are really what they are asserted to be.

In the matter of coal dust, there are possibly more theorists in the coal field than one could believe possible. They say that they cannot see how coal dust can explode without the presence of gas. A lot of needless experimentation has been conducted in America and in England to show that it can and that it does. It is remarkable that shrewd, practical men who in all their experiences apply the pragmatic test: "Does the action happen, or does it not?" in the matter of coal dust and its ignition apply only their powers of reasoning despite the lack of evidence on which that reasoning is based, and say that what repeatedly happens in America, in England, in Belgium, in France and in Austro-Hungary, can never happen, because it contradicts the laws of nature.

In such cases, duplication is necessary, but there is work which there is no need to repeat, and which will appeal just as forcibly if it is quoted in the bulletins of the bureau as it would if it formed a part of the actual operations of that organization. All institutions desiring to make investigations should make such intention known, that they may be allowed a clear field and leave a clear field to others. Mining investigation should be conducted as is astronomical research, across international lines, with frequent *pourparlers* between the scientists of all nations. It is reported that as a result of recent visits to the foreign stations, such an understanding has been effected.

The Inspection of the Bureau

The visitors first entered the long building on the opposite side of Butler street from the Arsenal. Here was inspected the physical laboratory, where high temperatures are measured, and physical apparatus and instruments calibrated. Experiments are proceeding on thermal conductivity at high temperatures and on the explosibility of mine gases. In another room was exhibited the bomb calorimeter, in which solid and liquid fuels are burned and their heating values (B.t.u.) determined. In the boiler room, hand-fired return-tubular boilers were shown arranged for smoke prevention, and here also were several types of domestic heating boilers, where waste, small in each unit but large in aggregate, is being studied.

A visit to the small but useful library of about 3000 volumes, conveniently situated about two blocks away from the point where they need to be used, followed and the visitors examined three rooms in which mining-engineering investigations are being made. The fuel

laboratory was then exhibited, where proximate and ultimate analyses are made of coal, lignite, peat and coke, and analyses of mine and boiler water, ash and slag. The petroleum laboratory, the next point of call, was devoted to the inspection and analysis of petroleum. Here some interesting experiments are being made on petroleum and its products.

In two other rooms the chemical constitution of coal is under examination. The chemists are endeavoring to find the actual compounds which enter into its composition. This work is done, not by distillation and burning of coal to get the percentage of volatile matter and of ash, nor by direct chemical action on the various parts, but by the use of solvents of different kinds, which dissolve the many compounds out of the coal probably without chemical change. Thus liberated from their environment, they can be concentrated from the solvents, seen, weighed, analyzed and their individual characteristics determined. Here also Doctors Frazier and Schnelling are making some valuable researches into the nature of explosions.

In the gas laboratory, investigations are being conducted into mine air and natural gas, the possibility of converting the latter into gasolene, and the effects of noxious mine gases on the well being of men and animals. In yet three other rooms are conducted investigations into the destructive distillation of coal, its weathering and spontaneous combustion, and the power of coal to store up various gases, alien and self created, within its pores. Another room visited was the photographic laboratory.

In the last three rooms were located the chemists whose work it is to analyze black powders, dynamite and permissible explosives, to determine the stability or effective life of stored explosives and the amount of the exudation of nitroglycerin from its absorbents on storage.

Address of Welcome

Somewhat belated, occurred the address of welcome of the director, Joseph A. Holmes, which was delivered at the rear of the Arsenal in between the motley congeries of buildings with which the reader has already been made familiar.

The guests of the bureau then viewed the testing of various incandescent lamps in an explosive mixture of gas and air. Some on being broken caused an explosion, and some did not, their relative safety being determined largely by the size of the filament, the temperatures to which that filament was heated and the speed with which the filament was burned away.

In another building, from a foundry cupola, gas samples were being taken and temperatures being observed of various horizontal zones of a coke bed. The expectation is that with a knowledge of the chemical action and intensity of heat at various levels, some information may be gained, which will make possible valuable changes in coking methods. A gas producer was also being studied, the fuel being burned at high temperature and capacity and the slag in a liquid condition, being removed by tapping.

The bureau has been experimenting on the use of limestone in this connection, to facilitate the fluxing of the slags which otherwise would clog the taphole. The smokeless combustion of low-grade fuel, high in volatile components, in a furnace fired by mechanical stokers was being exhibited in another building. If the soft-

Testing for Gas

coal man relishes but little the work for power economy, done by the bureau, the work for smokeless combustion interests him much, for by it he is enabled to draw on territory regarded as exclusively the domain of the anthracite operator and his sales agent. But above all, he looks to the bureau to encourage the sale of slack coal by these demonstrations of its efficiency and smokelessness when fed by mechanical devices.

The value of an exterior combustion chamber was then demonstrated, and the Murphy system exhibited. It is expected that the best method of making steam in a boiler will be found to be that of using an external combustion chamber; one where the progress of combustion is unchecked by the presence of large bodies of iron backed by water at relatively low temperatures. The heat in such an arrangement, being extracted in its entirety from the fuel, will be conveyed by the heated gas to the boiler. As it now is, in the ordinary boiler, the heat of partial combustion is utilized to heat water when it is more needed to complete the burning of the fuel, and thus obtain the heat units from the evolved gas and comminuted carbon.

In building No. 17, which lies at an angle to the rest, as if trying and failing to get a view of the Arsenal lawn beyond, single- and double-gauze safety lamps were tested in a current of air of known velocity containing 8 per cent. of natural gas. In another room, men wearing various types of breathing apparatus were training, in noxious gases, to perform the work of mine recovery.

The apparatus for the physical testing of explosives was then exhibited, including the large as well as the small impact machines, and the cone and pendulum friction device. In another building, a machine was running converting California lignite into merchantable briquets.

The spectacular events of the morning followed. A permissible explosive, having a strength equal to that of ½ lb. of 40 per cent. dynamite, tamped with 1 lb. of dry fireclay, was fired in the cannon of the dust and gas gallery No. 1, which was filled for the occasion with 7 per cent. of natural gas. No explosion followed, but when an exactly equivalent experiment was tried with black blasting powder FFF, the result was a violent explosion with a flame, which emerged from the end of the tube, opening every port hole in the gallery and enveloping the yard with smoke. A coal-dust explosion in miniature was exhibited in a laboratory apparatus designed for that purpose. As a final *tour de force,* in gallery No. 2, an electric mine locomotive with explosion-proof protective devices removed, on being operated in an explosive mixture of gas and air, caused a violent explosion.

The Mine Hospital

The ideal mine hospital should, if possible, be cut into the rock, and where this is not practical, concrete should be used for the walls. Such hospitals should be equipped with steam heat, hot and cold water and a sterilizing plant. Iron-doored, damp-proof closets for bandages, gauze, splints, etc., should be set in the walls. A dressing chair, dressing couch, stretcher and a first-aid kit will complete the equipment. The kit is for use at the working face, in case of serious accidents, where the patient must receive some attention before being transported to the hospital.

Methods of Testing Explosives

Special Correspondence

The tests of the explosives section, Bureau of Mines, are both chemical and physical. This article details the methods by which permissible powders are proved for the recommendation of the department to the mining industry.

The section of the Bureau of Mines devoted to the study and selection of explosives for use in the mines is a leading part of the Mine Accidents Division and though not more interesting than other sections is one of paramount importance in the safeguarding of the mines from disaster.

Principal among the apparatus for determining the action and acceptability of explosives is the gas and dust gallery No. 1, a cylindrical gallery 100 ft. long with a minimum internal diameter of 6 ft. 4 in. It consists of 15 similar sections each 6 ft. 8 in. long, connected by lap-riveted joints. The first three sections, those nearest the concrete head, and therefore receiving the main brunt of the explosion, are made of ½-inch boiler-plate steel; the remaining twelve sections are of ⅜-in. steel of like character, capable of resisting a tensile stress of at least 55,000 lb. per square inch.

Fig. 1 exhibits clearly the form of the chamber. To the right can just be seen the concrete head within which the charge is ignited. Along the top are visible the rows of release pressure doors, one in the center of each section, each provided with a rubber bumper to prevent destruction of the door when opened violently by the force of an explosion. These doors in use can be closed and fastened by the studbolts provided for that purpose, or they can be closed and left unfastened or left open during the explosion, as may be desired.

At each of the lap joints connecting the sections and on the interior of the cylinder there is a 2½-in. angle iron making a full circuit of the internal perimeter and upon the face of this angle iron, a paper diaphragm may be placed and held in position by semicircular washers, studs and wedges. These paper diaphragms are used only to confine the gas and air mixture before the explosion.

Along the lower part of each section at its center are placed windows measuring 6x6 in., made of ¾-in. plate glass.

The natural gas used is from the distributing mains of the city of Pittsburg, a typical analysis of which is as follows:

Carbon dioxide	0.0 per cent.
Oxygen	0.2 per cent.
Heavy hydrocarbons	0.0 per cent.
Carbon monoxide	0.0 per cent.
Methane	85.3 per cent.
Ethane	11.8 per cent.
Nitrogen	2.7 per cent.
	100.0 per cent.

It has been found that the gas in the mains is of uniform percentage and furnishes therefore a reliable basis on which to compare different explosives.

The volume of gas entering the gallery is accurately measured by a meter reading to 1/20 of a cubic foot. The gas enters the required division (consisting of three sections) or divisions of the gallery near the bottom of the cylinder from a 2-in. perforated gas pipe 14 ft. long. The perforations are so arranged that an equal flow of gas is maintained from each unit length of this pipe.

Each division is further equipped with an exterior circulating system, providing an efficient method of mixing the gas with the air. For the first division this circulating system is stationary, a portion of the piping being equipped with heating coils for maintaining a constant temperature of the mixture. All other divisions have a common circulating system mounted on a truck which may be used on any one of these divisions. Valves are provided for isolating the fan, so that a possible explosion will not injure it.

Gas and Dust Gallery No. 1, Fifteen Seconds after Explosion

The center section of each division is provided with an indicator cock, which is used for two purposes: 1. For indicators to record pressures above and below atmosphere. 2. For providing an opening where samples of the mixture may be procured. All divisions of the gallery are equipped with shelves laterally arranged for coal dust.

The cannon in which the explosive is fired is embedded in a concrete head, the axial line of the bore hole being coincident with the axial line of the gallery. The cannon consists of two parts, a jacket and a liner. The jacket is 36 in. long, 24 in. external diameter and 9½ and 7½ in. internal diameter, and is made of best cast steel, cast iron or vanadium steel. The liner is 36½ in. long, with a 1-in. shoulder 7¾ in. from the back, changing the diameter 9½ in. to 7½ in., having a smooth

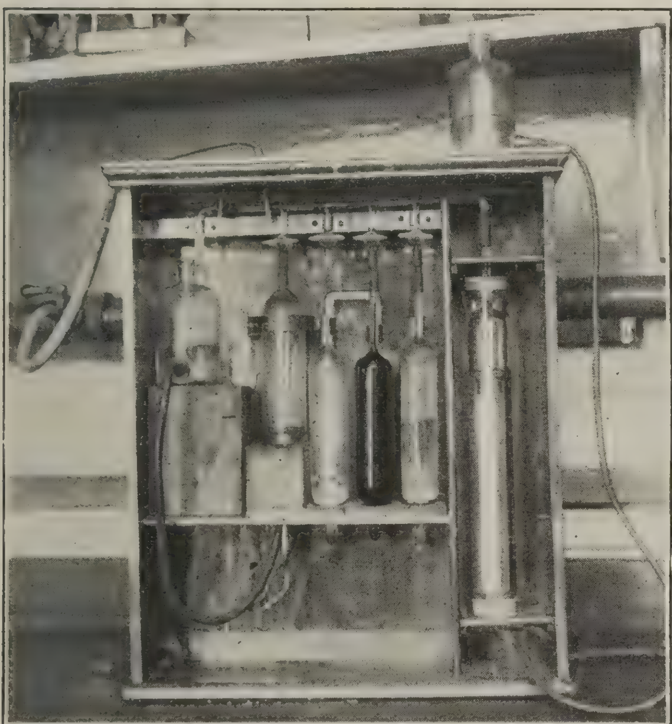
bore 2¼ in. diameter and 2½ in. deep. The face of the cannon is even with the face of the concrete head.

It might be well to add that the strain on the cannon used by the bureau is considerable, for the powder used is of more strength than that used for artillery purposes. Moreover, powders for military and naval uses are made in compressed hexagons of large size so that they act slowly and continue to explode till the shot has left the cannon. If it were not for this provision none of the larger-bore guns used in military practise could withstand the strains to which they would be subjected. As it is, their life is short. Looking at these shorter cannon they seem needlessly heavy until the this, of course, to assist in maintaining a constant temperature.

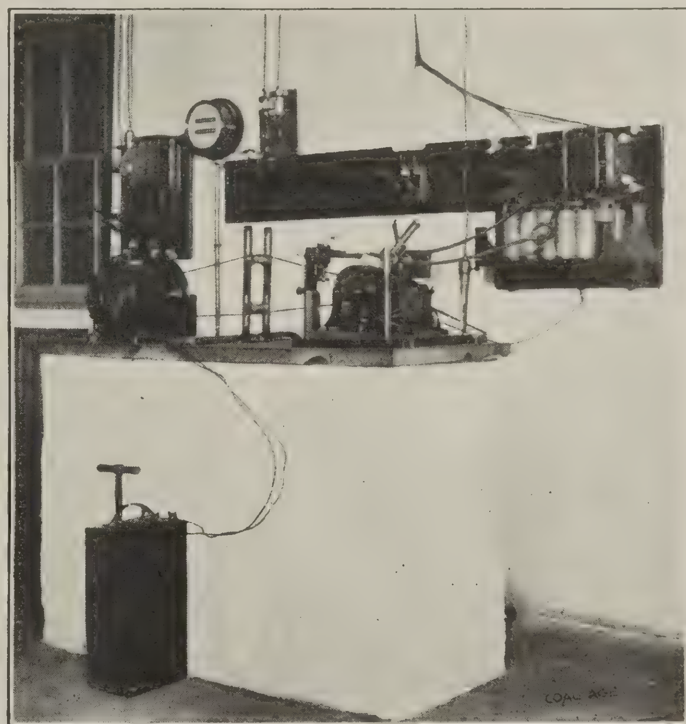
The entire gallery rests on a concrete foundation 10 ft. wide, having a maximum front hight of 4 ft. 6 in. and a minimum hight of 2 feet.

The concrete head in which the cannon is placed completely closes that end of the gallery. A narrow drain, extending under the tube its entire length, with a tapped hole at the bottom of each section, provides an efficient method for drainage.

The buildings near the gallery are protected by two barricades near its open end, each 10 ft. high and 30 ft. long. A back stop 6 ft. high and 9 ft. long, 50 ft. from the end of the gallery, prevents to control the quantity of steam flowing through them and are inclosed in a tight wooden box, approximately 2 ft. 10½ in. by 3 ft. 7 in. by 5 ft. 5 in. The air enters this box through a rectangular hole 10x12 in. in the end of box, also through 25 round holes 2 in. in diameter. A baffle board 12x19½ in. is set inside the box opposite the large opening to distribute more evenly the current of air over the surface of the radiators. The air leaves this warming box through an 11¾x30-in. opening and is carried upward by suitable boxing to a compartment 3 ft. 8¼ in. by 12 in. by 14 ft. 2½ in., which contains the humidifier heads. From there it goes through No. 15 doorway in the top of gallery, the end of the gallery



A Modified Form of the Orsat Apparatus



Apparatus Measuring Rate of Detonation

reason for their immense strength is made obvious by due consideration, the arguments being amply fortified by the experience of the bureau. Replacements of cannon furnish an important item of expense in the disbursements of the bureau.

The charge is fired electrically from the observation room and, that the risk of charging the cannon may be minimized, the charger carries in his pocket the plug of a stage switch (this being the only one of its kind on the grounds), so that it is impossible to complete the circuit until he has left the gallery.

That portion of the first division of the gallery which is not in concrete has a 3-in. covering, consisting of blocks of magnesium, asbestos fiber, asbestos cement, a layer of 8-oz. duck, and then a dryproof roofing and the whole covered with a thick coat of graphite paint; all any of the stemming from doing damage.

The tests are witnessed from the observation room, a protected position about 60 ft. from the gallery. The walls of the room are 18 in. thick and the line of vision passes through a ½-in. plate glass 6 in. wide and 37 ft. long, and is further confined by two external guards, each 37 ft. long and 3 ft. wide.

When humidity tests are run on gas and dust gallery No. 1, the apparatus is further equipped as follows: To the 14-in. doorway of section No. 1 is connected by suitable boxing a Koerting exhauster of 240,000 cu.ft. of free air per hour capacity. No. 15 doorway is used as the air inlet and to it are connected by suitable wooden boxes a compartment that contains steam radiators and the humidifiers. Three 38-in. triple-column radiators, averaging 310 sq.ft. of heating surface, are arranged with valves being efficiently closed by brattice cloth and a paper diaphragm.

The Ballistic Pendulum

The ballistic pendulum is used for the purpose of measuring the disruptive force of a unit charge of any explosive. The unit disruptive force is defined as being that force which is required to swing the pendulum through an arc equal to that through which it is swung by a charge of one-half pound of 40 per cent. nitroglycerin mixed with the standard absorbents required by the bureau.

The apparatus consists essentially of a cylindrical weight in the form of a mortar, weighing 31,600 lb., suspended on knife edges, and a steel cannon mounted on a truck which runs on a short track. The truck is parallel with the direction of the swing of the mortar, and the cannon at the time of firing may be placed 1/16

of an inch from the muzzle of the mortar. The mortar is suspended from a beam supported by concrete walls 139 in. high, 51x120 in. at the base. On top of each wall is a base plate anchored to the wall. The knife edges rest on bearing plates placed on top of these base plates. Each bearing plate is provided with a small groove for the purpose of holding oil to lubricate the knife edges and to protect them from the weather. Each knife edge is 6 in. long and the bearing surface is rounded to conform to a radius of 1/4 of an inch. The mortar rests on two U-shaped saddles which pass through heavy steel castings bolted to the beam. The vertical distance from the point of the knife edges to the center of the trunnions of the mortar is 89 3/4 inches.

The cannon used on the truck are similar in size and material to those used in gas and dust gallery No. 1. The truck consists of four wheels set to a 30-in. gage and the track extends about 9 ft. from muzzle of mortar to bumper.

The shot is fired from the first floor of building No. 17, about 10 yd. from the pendulum, by means of an electric firing battery. The man who charges the cannon carries a safety plug from a stage switch when working and is thus protected in the same manner as the charger at gas and dust gallery No. 1.

A recording device is placed at the back of the mortar, and is connected to it by means of a horizontal rod at the end of which is a circular face. A lug inserted in the bottom of the mortar directly below its center of gravity pushes this rod, thus transmitting the length of the swing to a scale at the other end of the rod. By means of a vernier the length of swing is recorded to the 1/200th part of an inch.

Trauzl Lead Blocks

The Trauzl lead-block test is the method adopted by the Fifth International Congress of Applied Chemistry as standard for measuring the unit disruptive force of explosives. The unit disruptive force of explosives thus tested is defined as the force required to enlarge the bore hole in the block an amount equivalent to that produced by 10 grams of standard 40 per cent. nitroglycerin dynamite stemmed with 50 grams of dry sand, under standard conditions as produced with a tamping device. The result of these tests when compared with those of the Bichel gage indicates that for explosives of high detonation the lead block is quite accurate, but for slow explosives the expansion of the gas is not fast enough to make comparative results of value, the gases escaping from the bore hole in the block rather than taking effect in causing its expansion.

The lead blocks are cylindrical in shape, 200 mm. (7.88 in.) in diameter and 200 mm. high. Each has a central cavity, cylindrical in shape, 25 mm. (0.988 -in.) in diameter and 125 mm. (4.925 in.) deep, in which the charge is placed. The blocks are made of desilverized lead of the best quality and as nearly as possible under identical conditions. The charge is placed in the cavity and prepared for detonation with electric exploder and stemming. No yoke is used and no additional attempt is made to further confine the charge. The bore hole after the explosion is pear shaped, the size of the cavity depending not only upon the disruptive power of the explosive, but also upon its rate of detonation as described above. The size of the bore hole is measured by running in water from a burette until the cavity is just full. The difference between the original size of the cavity and its size after detonation is of course the enlargement produced by the explosion.

Ballistic Pendulum for Determining Disruptive Force of Powder

The Explosion Calorimeter

The explosion calorimeter is designed to measure the quantity of heat given off by detonation of explosive charges of 100 grams. The apparatus consists of a calorimeter bomb, the inner receiver or immersion vessel and wooden tub, a registering thermometer and a hooking frame.

The bomb is bottle-shaped, of 1/2-in. wrought steel, and has a capacity of 30 liters (31.7 quarts). On opposite sides near the top are bored apertures, one for the exhaust valve, for obtaining a partial vacuum, measured by about 10 mm. (0.39 in.) of mercury column, after the bomb has been charged; the other for inserting the insulated plug through which passes the fuse wire for igniting the charge. The bomb is closed with a cap, by means of which the chamber may be made absolutely air tight. The bomb weighs 158 lb., is 30 in. high with the cap on, and is handled to and from the immersion vessel by means of a small crane.

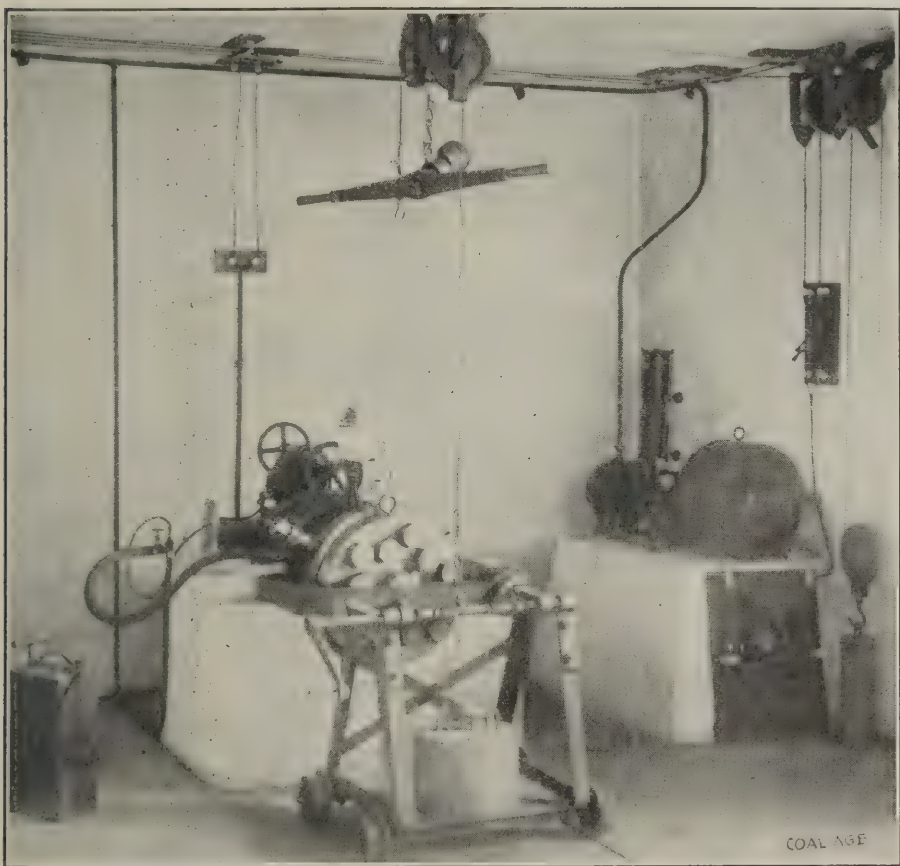
The inner receiver is 30 7/8 in. deep, 17 7/8 in. inner diameter, and is made of 1/16-in. sheet copper, nickel plated, and strengthened on the outside with bands of copper wire. The outer tub is 30 in. deep, 21 in. inner diameter, is made of 1-in. lumber, and is strengthened with four brass hoops on the outside.

The stirring device consists of a small wooden beam connected to a system of three rings, having a horizontal bearing surface, and is operated vertically by means of a worm gear run by an electric motor. When the apparatus is put together the inner receiver rests on a small standard on top of the base of the outer tank. The rings of the stirring device run between the bomb and the inner receiver. The bomb itself rests on a small standard placed on the bottom of the inner cylinder. The apparatus is provided with a snugly fitted board cover.

The rise in temperature of the water is read from a Centigrade thermometer measuring to the one-hundredth part of a degree. The hight of the mercury column is read by means of a magnifying glass.

The bomb is charged from the top, the explosive being suspended in the center. The caps are then screwed on, the apparatus set together as above described, first, however, exhausting the air to the desired degree of rarefication.

The apparatus is assembled on scales before the water is poured in and the weight taken, and then it is weighed after the receiver is filled with water. By obtaining the weight of the water in this way and knowing the temperature, the calorific value may be computed. The capacity of the inner receiver is about 70 liters (74 quarts). The charge is exploded by electricity while the water is being stirred. By combining the quantity of heat of the explosive in calories with the specific heats of the products of combustion at the proper temperatures the maximum temperature of explosion may be arrived at.



BICHEL PRESSURE GAGE, MEASURING PRESSURES FROM COMBUSTION OF EXPLOSIVES

Rate of Detonation Apparatus

This apparatus for measuring the rate of detonation is used to determine the velocity with which detonation travels through a given length of an explosive. For this purpose the explosive is placed in a long galvanized iron tube 38 mm. (1.496 in.) in diameter and 1.22 meters (4 ft.) in length and suspended in a pit. This pit is 11 ft. deep, 16 ft. in diameter, and is provided with a steel-plate casing backed by a cushion of sawdust and with a heavy cover consisting of large timbers, covered by reinforced concrete, and anchored to the ground with eight deadmen. By means of electrical connections at each end of the tube connected to the recording device known as Mettergang's recorder, placed in an adjacent building, the interval of time elapsing between detonation at the two ends of the tube is accurately measured on a smoked drum revolving with a known peripheral speed. In using such small lengths of explosive as one meter it is obviously essential that very minute differences in time be recorded. The recording device is conveniently equipped in such a way that one one-hundredth part of a millimeter may be measured. The drum is 500 mm. in circumference and its normal speed is 86 revolutions per second. The smallest time interval that can be measured, therefore, is 1/4,300,000 sec. The usual length of explosive used is one meter and the sticks of explosive are, after cutting off their ends, placed end to end.

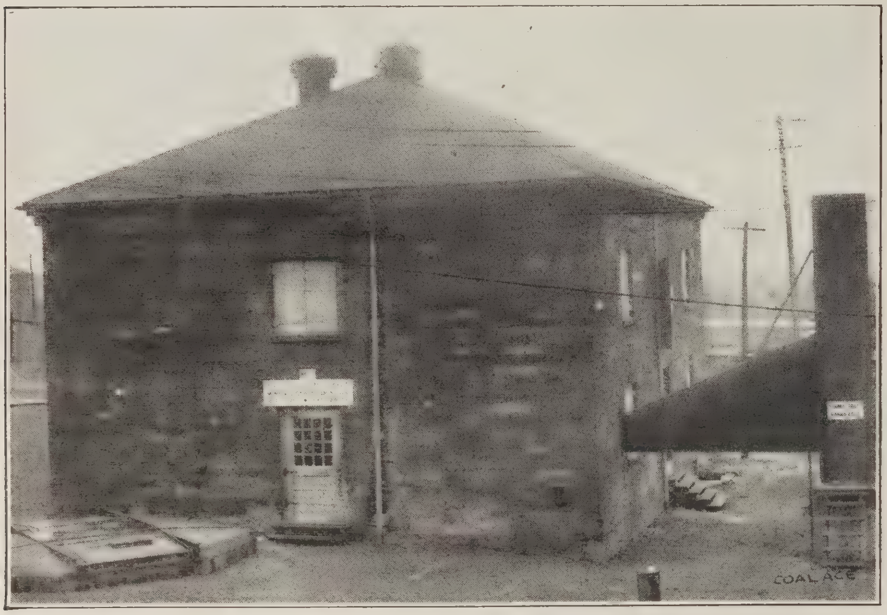
Flame-test Apparatus

The flame-test apparatus was designed for measuring the length and duration of flame given off by explosives. It consists essentially of a cannon, a photographic instrument and a drum geared for high speed, to which a sensitized film may be fastened. About 13 ft. from the outside wall of the building in which the test is observed is set the foundation for the cannon and incasing cylinder or shell. Set on top of this is a cannon identical with the one used for the gas and dust gallery No. 1, the details of which are included in the description for that apparatus. The shell or cylinder is set on top of the concrete and is concentric with the cannon, and is 43 in. internal diameter, 20 ft. high, constructed of ¼-in. boiler plate in 24 sections and made absolutely impenetrable to light on the sides and base. Riveted to the shell and connecting it with a dark room in an adjacent building is a light-excluding conduit of rectangular cross-section, 12 in. wide on the inside, horizontal on the bottom, sloping on the top from a hight at the cylinder of 8 ft. 3 in. to 21 in. at the inside of the wall of the building. It is carefully insulated from light by means of oakum packing at the joints in the building, and when not in use two small steel doors isolate the dark room from the light leaking from the top of the shell. A vertical slit is cut in the shell 2 in. wide and 8 ft. long coincident with the center line of the conduit. A vertical plane drawn through the center line of the bore hole of the cannon and of this slit, intersects the center line of the quartz lens, the center of the stenopaic slit immediately in front of the film and the axis of the drum on which the film revolves. The photographic apparatus consists of a shutter; a quartz lens placed in such a position as to focus the rays of light, including the ultra-violet rays, which are those attending extreme heat; a stenopaic slit between the lens and the rotary drum, 76 mm. (3 in.) long and 1.7 mm. (0.067 in.) wide; a rotary drum 50 cm. (19.68 in.) in circumference and 10 cm. (3.9 in.) deep, geared to and driven by a 220-volt motor, which is connected to a tachometer reading in both meters per second and revolutions per minute. A maximum peripheral speed of the drum of 20 meters (65.62 ft.) per second may be obtained. The speed is regulated by a rheostat. The drum, gears, shutter, lens, stenopaic slit and connecting apparatus are inclosed in a box which excludes all light, for convenience in order that the film may be left on the drum in position should the operator desire to leave the dark room. One hundred grams (0.22 lb.) of the explosive are used in the cannon and the firing line extends from the cannon to the dark room, from which place the shot is fired. The firing line is equipped with a stage switch as a precaution.

With the drum at rest the flame is shown on the film as a vertical line of a width equal to the stenopaic slit and by simple proportion the exact hight of the flame may be determined. When the drum is in rapid motion of known velocity not only the hight of flame but the duration may be computed by measuring the lateral displacement on the film and applying it to the known peripheral speed.

The Impact Machine

The impact machine is designed to determine the sensitiveness of an explosive to shock. For this purpose a drop hammer is used, constructed in such a way as to meet the following requirements: 1. The necessity for having a substantial unyielding foundation, of constant temperature. 2. Minimum friction in the guide grooves so as to approximate the conditions of a freely falling body. 3. Prevention of escape or scattering of the explosive when struck by the falling weight.



Flame-test Apparatus Measuring Duration and Hight of Flame

The apparatus consists essentially of the following parts: an endless chain working in a vertical path operated by electricity and provided with two lugs equally spaced; a steel anvil upon which the charge of explosive is placed; a steel stamp pressing on top of the charge and holding it in position; a magnetizing collar operating freely in vertical guides and provided with small jaws in the rear so placed that the lugs of the chain engage them; a steel weight which operates loosely in vertical guides and is drawn by the magnetizing collar to determinable hights when the machine is in operation; a demagnetizing collar which may be set at known hights and which is provided with a release for the jaws of the first collar, and a recording device geared to a vertically driven threaded rod which sets the demagnetizing device and thus determines the hight of fall of the weights.

The apparatus is supported by a concrete pedestal which is set at a convenient hight for the operator. The heavy oval-shaped steel base of the machine itself is anchor-bolted to this pedestal and into the base is screwed the anvil on which the charge of explosive is placed. The main standard of the apparatus is about 65 in. high and $2\frac{1}{4}$ in. diameter, shrunk into a flanged collar which is screwed into the base plate at the rear. The collar guides are $\frac{5}{8}$-in. rods and extend from a plate securely fastened to the top of the flanged collar at the base of the main standard to the plate of the apparatus. The steel stamp which transmits the blow of the fallen weight is $7\frac{1}{2}$ in. high, $1\frac{1}{8}$ in. in diameter, tapered at the base to a small cylinder $\frac{3}{8}$ in. high and $\frac{3}{8}$ in. in diameter, which operates at the center of the anvil. The drop hammer weighs 2000 grams (4.41 lb.) and moves in loose-fitting guides which produce a minimum of friction. The hammer is dropped from varying hights until detonation takes place. A maximum safety hight is determined when five attempts to explode a charge fail at that hight, and if five or less than five attempts at that hight plus one centimeter, (0.39 in.) give at least one explosion.

Care is taken that the anvil and stamp are well cleaned after each test. The whole apparatus when not in use is covered with oil and provided with a hood.

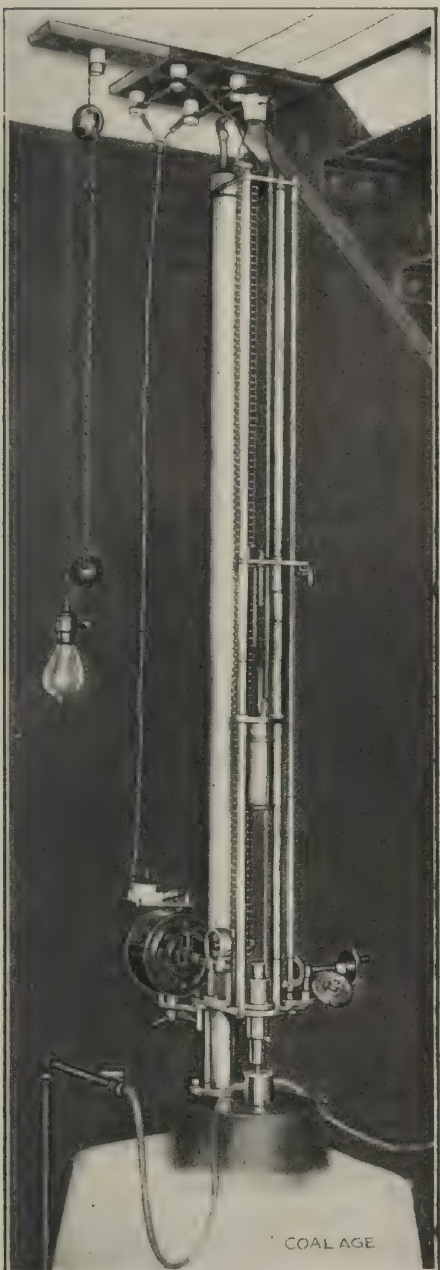
In order to maintain a uniform temperature while experimenting, water at a temperature of 25 deg. C. (77 deg. F.) flows through the anvil.

The Explosion by Influence Tests

For explosion by influence the pit described when detailing the apparatus for testing the rate of detonation is used, and two sticks of each explosive are required. The sticks are placed end to end, separated by a certain distance, always a multiple of one inch, and the pair suspended in a vertical position. The lower stick

Calorimeter Used to Determine Heat of Combustion of Explosives

is detonated. This detonates or fails to detonate the other, the action or failure to act depending upon the distance between the sticks and the sensitiveness of the explosive to detonation in this manner. The maximum distance of explosion by influence is established if the second stick explodes at that distance and fails to explode three times at that distance plus one inch.



Impact Machine

Rate of Burning of Slow Explosives

The test of the rate of burning of slow explosives is performed in the same pit and the explosive is placed in a water pipe having an inside diameter of $1\frac{1}{4}$ in. One end of this pipe is closed with a plug, the other end being free. The fuse is placed in the free end and the explosive burns toward the plug. Insulated annunciator wires are placed through the explosive one meter apart and the time of burning is indicated by sparks on the Mattergang's recorder, but the time interval between the sparks is taken by means of a stop watch.

Care is taken that the density of the explosive is normal.

Bichel Pressure Gages

The Bichel pressure gages are used for determining the strength of explosives by measuring pressures developed in an inclosed space in which an escape of generated gases is rendered impossible. The apparatus consists of a stout steel cylinder which may be made absolutely air tight, an air pump and proper connections for exhausting the air in the cylinder to a pressure of 10 mm. of mercury, an insulated plug for providing the means to ignite the charge, a valve by means of which the gaseous products of combustion may be removed for subsequent analysis, an indicator and drum, with proper connections, for driving it at a known speed.

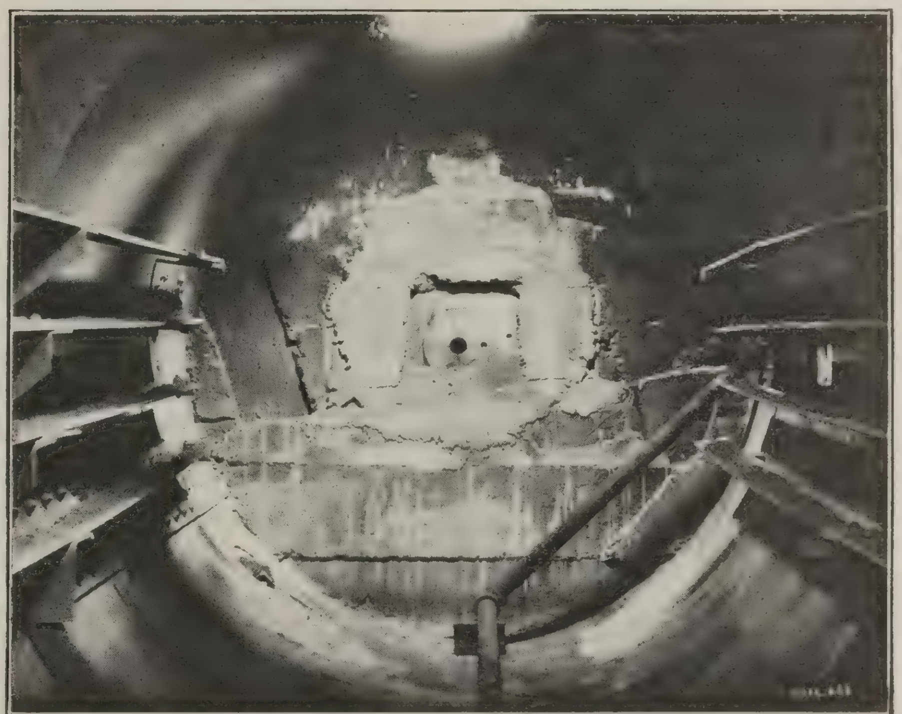
The cylinder rests on a solid concrete footing at a convenient hight for handling. It is $31\frac{1}{4}$ in. long, $19\frac{3}{4}$ in. diameter, and anchored to the footing. The explosion chamber is 19 in. long and $17\frac{7}{8}$ in. diam., having a capacity of exactly 15 liters (1585 quarts). The cover of the cylinder is a heavy piece of steel held in place by heavy steel studs and nuts and a yoke.

The charge is placed on a small wire tripod, and connections are made with a fuse to an electric firing battery for igniting the charge. A near-vacuum is produced by means of an air pump in order to more closely approach the conditions of a tamped charge exploding in a bore hole inaccessible to air. When the charge is exploded a record is made on the indicator card. This shows a rapidly ascending curve for quick explosives, grading into a shallower curve slowly rising for explosives of slow detonation. When the gases cool, the curve merges into a straight line, which indicates the pressures of the cooled gases on the sides of the chamber.

Finding Pressure of Charge

Since the volume of the chamber is nearly 75 times that of the volume of the charge, the pressure of the charge confined in its own volume may also be found. The cooling influence of the inner surface upon the gaseous products of combustion is a vital point in computing the pressure developed by an explosive. Its effect is eliminated by comparing the pressures obtained in the original cylinder with those of a second cylinder of a larger capacity into which has been inserted one or more steel cylinders, thus increasing the superficial area while keeping the volume constant. By comparing the effect of the increased cooling surface with the original a curve may be plotted which will determine the actual pressures developed after the elimination of the surface influence.

The black-powder separator is made similar to the separators used in powder mills, but of reduced size.



Concrete Head, Cannon, Dust Shelves and Distributing Gas Pipe in Gallery No. 1

Illustrations of First Aid Work

By M. J. Shields*

Describing in detail the most approved methods of treating injured miners. The illustrations present actual work performed in the Government mine at Bruceton, Pennsylvania.

*First Lieutenant, M. R. C., U. S. A., American Red Cross Society.

The illustrations with which this article is accompanied are representations of actual work performed in the Bruceton mine, of the U. S. Bureau of Mines. The patient in Fig. 1, is supposed to have a compound or open fracture of the arm, with bleeding. The first thing to do is to raise the forearm so that the elbow is bent. Elevating the arm tends to stop the bleeding, by decreasing the pressure in the veins, and this in itself eases the pain.

The Red Cross tourniquet is being applied. This is a simple affair; nothing more than a straight and strong piece of webbing, which is passed around the arm, and which is secured by a clasp, having small teeth. When the clasp closes on the webbing, a strong spring holds it firmly in place. The pressure on the blood vessel is attained, as will be seen, by placing a small block over the artery to be compressed; the artery in this case of which the circulation is to be stopped is the "brachial" or main artery of the arm, which runs in a course corresponding to the inside seam of the shirt of the patient when in place.

The hemorrhage is now stopped, and it is necessary to attend to the fracture. But first observe how carefully the attendant on the left is supporting the arm of his patient (Fig. 2) with a deft placement of his own forearm, so that the fracture is not aggravated. At the same time, he places his left thumb on the bandage to hold it in place while his companion applies the pressure.

The wound is first covered with aseptic gauze, to keep infection away, then the arm is bandaged to keep the gauze in place. This bandage is light, and care must be taken not to have it unnecessarily thick where the splints will later come. The splints, which consist of boards ⅜ of an inch thick and about 3 in. wide, are applied to both sides of the arm, these boards or splints being padded with cotton.

Splints Are Made of Yucca Wood

It might here be said that the splints preferably used are made of Yucca wood, which is brought from California. The wood is soft and easily bent to fit the arm, especially when it has not been kept in too dry a place. The inside splint extends nearly to the ends of the fingers, so that the last joints can be passed down over the end of the splint, if the patient so desires. The splints should always be long enough so that they will extend well beyond each side of the fracture, but, of course, it will often happen that the first-aid man will find himself unable to find splints of the kind here described, in which case he will avail himself of any stiff piece of wood, whether it fits the arm or not, but he will bear in mind that the primary consideration is that the splint shall effectually span the fracture. After this, either triangles or bandages are applied to hold the splints in place. The pain of a fracture is usually relieved by a well applied splint.

The arm is then placed in a flexed position, with the thumb pointing toward the nose of the patient, as shown in Fig. 3. One point of the triangle is thrown over the left shoulder, and the body of the bandage is permitted to fall over the front of the patient between his stomach and his arm. The point which is now lowest is folded back over the outside of his arm and passed over his right shoulder, and tied to the other point at the back of his neck. The third point now projects untidily from the end of the elbow, and should be folded over and pinned so as to secure the elbow in place as indicated in Fig. 4.

Fracture of the Rib

The patient in Fig. 5 has fractured his rib. The man on the right is aiding the patient to hold up his arms. The patient is told to expire or throw out his breath, so that his chest will be reduced in girth. By this means, the bandage when applied will be tight. A wide, or 6-in., bandage is used, and the pressure on his side keeps his broken bone or bones in place. When a man has a fractured rib, he instinctively holds his hand over the fracture to prevent the motion which results from the inspiration and expiration of his breath.

Treatment of Facial Burns

The patient in Fig. 6 is supposed to be the victim of severe facial burns. His shirt is opened in front by the attendant and tucked into a roll all around his neck, so that the bandaging may be made to cover every burned part. Very little is done to clean the head of the patient. If any particles of dirt are seen, they can be removed if it can be done without

Fig. 8. Showing the Use of Pulmotor on an Asphyxiated Man

dragging or fingering of the wound. If the skin is burned to the clothing, it is not dragged off, but cut away with shears. Nothing is allowed to come in contact with the burn until the gauze is put on, and this is done soon, for delay means infection and shock. The patient is told to close his eyes, if infection has not already caused him to close them.

A large piece of picric-acid gauze is moistened either with steam, if that is obtainable, or with clean water. This should cover the burn completely. As the eyes and nose are burned, no holes should be left for them to project through the dressing. The patient can breath through the bandage and picric-acid gauze without difficulty, and it is essential, not only for his comfort, but also for the rapidity of his recovery, and for the avoidance of blood poisoning, that no portion of the burned cuticle shall be subjected to the germs with which the atmosphere is everywhere loaded. The acid warms the wounds and makes them more comfortable.

Holding a burn before the fire causes it to cease its smarting. In a like manner, picric-acid gauze comforts the wearer who is suffering with burns. Moreover, picric acid is aseptic and prevents infection. Care must be taken, however, that the picric acid does not come in contact with the uncovered eyeball; otherwise it will occasion some distress to the patient.

By throwing one point of triangular bandage over the head, the other two points can be passed around the neck in opposite directions to meet at the back and cross so as to keep the first point in place. They can then be made to reencircle the neck, and can be tied in front. This completely protects the wearer if the burns do not extend any distance toward his breast.

Dressing a Scalp Wound

Fig. 7 illustrates the use of the Red Cross first-aid compress-bandage dressing on a scalp wound on the right side of the head (temple). The compress dressing is a 4-in. bandage, with a gauze pad of 10 thicknesses sewn in the middle, which, when first taken from the first-aid packet, is folded in accordion pleats, so that when the attendant grasps it at either end and pulls, the compress remains in the center. Notwithstanding that his hands may be dirty and unclean, they can do the patient no harm, because it is not necessary for his hands to touch the wound or the compress itself. The bandage is passed twice around the head vertically, then crossed and passed around the scalp horizontally, over the temples. The attendant is shown making the final tie.

Finally the triangular bandage is placed over the head, but the method by which this is accomplished is not shown in the illustration. Two ends of the triangle are carried around the head and tied in front. If there is any bleeding, you can arrange the knot so that it is right over the source of the blood, which is oozing from the injured part, and, by drawing it tight, you can destroy the circulation and prevent further bleeding.

The Use of the Pulmotor

Fig. 8 shows an attendant using a pulmotor on an asphyxiated man. He has set him down sitting with his legs straight out before him. A rolled coat is laid on the ground a little below where his shoulders would come when he is laid out at full length. The erect portion of his body is then laid back so that his head rests on the ground, and his back is curved over the coat. In this manner, by bending his body, his throat is made perfectly straight and in the best of shape for breathing, real or artificial.

The tongue is drawn out by a retractor, which is a pair of light nippers which can be set in place so that no extra pressure has to be placed on them except at the time of application. The retractor is passed into a gas-tight bag, which forms part of the pulmotor, and the tongue is held up by holding the retractor through the walls of the bag. The pulmotor, which, of course, is already being held over the face of the patient, is now pressed forcibly over the nose and mouth, and the valve of the pulmotor is opened. The apparatus then automatically drives oxygen into the lungs of the subject. As soon as his lungs are full, the pressure reverses the valves in the pulmotor, and then it exhausts the waste gases, or the unused oxygen, from the lungs of the subject.

National First Aid Meet

By R. Dawson Hall

On Tuesday, Oct. 31, the National Mine Safety and First-Aid meet was held in the Forbes field, Pittsburg. The demonstration was attended by some 20,000 people, including President Taft, Secretary Fisher, Miss Mabel Boardman, Governor John K. Tener and Major Lynch. The first part of the program was the work of the Red Cross teams, 40 in all competing. The uniform of the men and their general deportment elicited much praise. Seeing that these men have been drilled in disconnected centers and that the Red Cross Society has not been able to provide all the assistance which it would have preferred to bestow, the work has been phenomenal.

There is no question but what the time was ripe for the work when Doctor Shields first took hold of it, and when the efficient organization of the Red Cross took it up. The 10 events were well performed. The enthusiasm of those who took part was unquestioned.

It is permissible, however, to criticize some few things, one especially which the teams have been urged continually to avoid. Respiration should never be restored by the Sylvester method when a man has badly burned or fractured arms. It is pathetic to watch some of the teams working badly wounded arms up and down in this sort of calisthenic exercise. Nor should the subject be allowed to put his mouth down on the ground when other forms of respiration are used. Just think what such a treatment might mean to a subject who really had such wounds, or had ceased to respire.

It is wrong to excuse a team by saying it is rattled. The men should never get confused, for a mine disaster develops the disease and only cool men should be chosen for first-aid work. The appearance of the men would be greatly improved if all, instead of about 90 per cent., were taught to deport themselves like soldiers, when not attending subjects. I would also suggest that all patients be placed in similar positions on the mats.

It seems, however, an ill acknowledgment of such excellent work to criticize what few things were wrongly performed. Still more unenviable would it be to pick out among so many excellent teams, one of superlative merit; the work was not to put the burden of choice on anyone else.

An account of the Bureau of Mines demonstration, which followed, must be omitted and left for another issue.

Explosions in Great Britain

The following is a list of the colliery explosions in Great Britain, with the date of occurrence and the number killed, that have occurred since 1851, involving the loss of 100 lives and over:

RECORD OF ENGLISH EXPLOSIONS

Mine and Situation	Date of Explosion	No. Killed
Cymmer, Glam	July 15, 1856	114
Lund Hill, Yorks	Feb. 19, 1857	189
Risca, Monmouth	Dec. 1, 1860	142
Oaks, Yorks	Dec. 12, 1866	361
Ferndale, Glam	Nov. 8, 1867	178
Swaithe Main, Yorks	Dec. 6, 1875	143
Blantyre, Lanarks	Oct. 22, 1877	207
Haywood Wood, Lanarks	June 7, 1878	189
Risca, Monmouth	July 15, 1880	268
Abercarne, Monmouth	Sept. 11, 1878	120
Seaham, Durham	Sept. 8, 1880	164
Naval Steam, Glam	Dec. 10, 1880	101
Clifton Hall, Lancs	June 18, 1885	178
Llanerch, Monmouth	Feb. 6, 1890	176
Park Slip, Glam	Aug. 26, 1892	112
Combs Pit, Yorks	July 4, 1893	139
Alboin, Glam	June 23, 1894	290
National, Glam	July 11, 1905	119
West Stanley, Durham	Feb. 17, 1909	167
Whitehaven, Cumberland	May 11, 1910	136
Pretoria, Lancs	Dec. 21, 1910	344

Thus, of 21 explosions in which 100 or more were killed, three occurred in February with 532 deaths; one in May with 136 deaths, three in June with 657 deaths; four in July with 492 deaths; one in August with 112 deaths; two in September with 432 deaths; one in October with 207 deaths; one in November with 178 deaths; five in December with 1091 deaths.

Explosion in Illinois Mine

By Floyd W. Parsons

It appears that the explosion in O'Gara mine No. 9 at Harrisburg, Ill., was caused by the ignition of a keg of blasting powder. A fortunate circumstance prevented a much higher death roll.

The most serious mine accident that ever occurred in Saline county, Illinois, took place Monday morning, Oct. 23, in O'Gara mine No. 9, at Harrisburg. Eight American miners were killed.

Immediately after the explosion, rescue parties were formed and made their way into the mine in an effort to save the men who were entombed. The rescuers were directed by Superintendent Morris, of the O'Gara Coal Company. Assisting Mr. Morris were William Johnson, general superintendent, and George Morris, assistant superintendent, of the Saline County Coal Company. After encountering serious difficulties incidental to the noxious fumes that followed the explosion, the rescuers succeeded in reaching the scene of the disaster and, by effective working, brought out a dozen men who were overcome by the gases.

After getting the affected miners to the surface, where they were placed under the care of doctors, the rescue party returned to the workings and continued their efforts until they reached the North entry where they found the bodies of 8 men who had succumbed to the effects of the gases following the explosion.

The dead were all found in rooms 14, 15 and 16, in the main North entry. None of the victims were disfigured, or seriously burned, but all were found with their faces covered—some with their hands and others having parts of their clothing drawn over their faces in a vain effort to keep out the poisonous gases. Several members of the rescue party were temporarily overcome by the gases, but were revived later.

About an Hour Elapsed

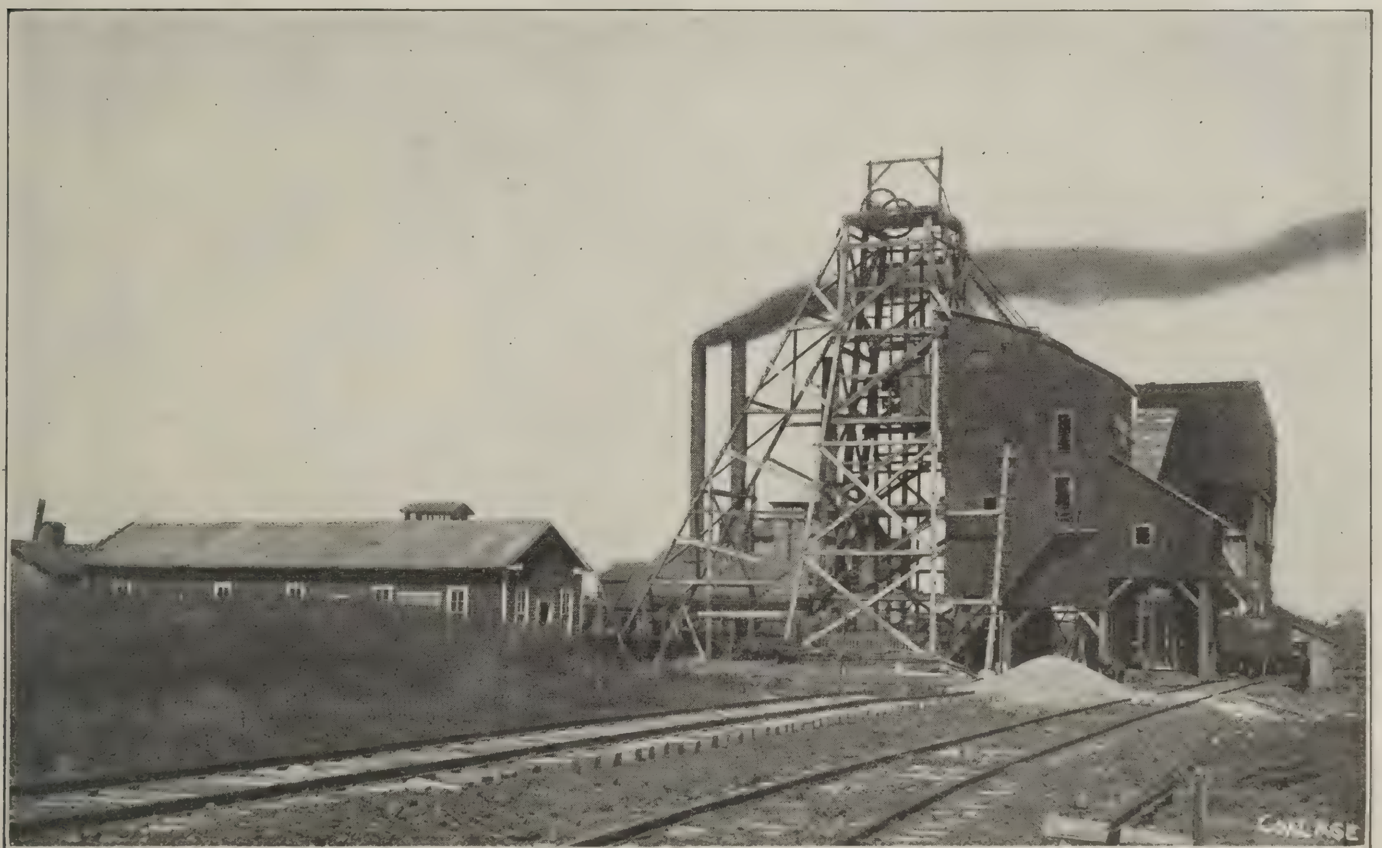
It was fully an hour after the explosion occurred before the rescuers got into the rooms where the bodies were found. The victims were immediately carried to the shaft bottom, and a little later taken to the surface where a temporary morgue was made available.

It is fortunate that only about 25 men were in that part of the mine where the accident occurred, and, aside from the 8 miners who lost their lives, the others either made their way out or were carried to the surface by the rescuers. It is reported that about 400 men were at work in other parts of the mine and were not affected by the explosion or the gases that followed.

Probable Cause

As is usual after a serious accident of this kind, a number of theories were advanced as to the cause of the explosion. The firebosses who examined the mine on the morning of the accident reported the workings free from gas. The company officials claim that the mine is not gaseous and has never been reported as dangerous. The workings are naturally damp so that no great attention was paid to moistening the dust. The seam that is worked averages over 6 ft. in thickness and lies 168 ft. from the surface.

The investigations seem to indicate that the explosion was caused by a keg of blasting powder which was accidentally set off. This theory is borne out by the statements of the rescuers who claim that when they entered the mine and ap-



O'Gara Coal Company's No. 9 Mine Where Eight Men Were Killed

proached the affected district, the powder fumes were so heavy that they had great difficulty in penetrating to the point of origin. If the explosion had been gas or dust this condition would hardly have been present.

A Fortunate Circumstance

In connection with this accident, it seems to me that fatalities would have been considerably heavier if the fumes of the powder that exploded had not been drawn into the adjacent mine, O'Gara No. 4, which was temporarily idle. The circumstances were as follows: The main North entry, just off which the explosion is thought to have occurred (in room 15), has an underground connection with mine No. 4. This latter mine was being ventilated by an exhaust fan although no men were at work underground. The force of the explosion blew out the stopping that connected the North main in mine No. 9 with the workings of No. 4, short-circuiting the air and causing the fumes and gases to be drawn out through No. 4 mine. The ventilator at No. 9 mine was working as a blower while No. 4 fan, as before stated, was exhausting.

It is quite probable, if the door connecting the two mines had not been blown down, the gases of the explosion would have been forced back through No. 9 mine, suffocating more men.

State Mine Inspector Rosbottom brought out the twisted and misshapen powder keg that is alleged to have been the cause of the disaster. This keg will be presented as evidence at the coroner's inquest. A few investigators have advanced the belief that the explosion was due to gas from mine No. 4 entering mine No. 9; however, there appear to be no facts to support this belief. The contention of the O'Gara people is that a lighted lamp was left near the keg of powder and in some manner fire from the lamp reached the powder, causing it to explode.

Considerable secrecy has been maintained by the O'Gara company in connection with this accident. No first-hand analysis of the explosion is possible, therefore, at the present time. Coal Age will publish the final verdict when the facts are made public.

Explosion Test at Bruceton Mine

By J. T. Beard

After some delay the mine was fired by an explosion of coal dust resulting from blownout shots.

The National Mine Safety Demonstration inaugurated and carried to a successful culmination under the auspices of the United States Bureau of Mines, American National Red Cross and the Pittsburg Coal Operators' Association, this week at Pittsburg, reflects great credit on the promulgators of the movement. The results proved that the effort was appreciated by the great body of mining interests in this country. No larger or more representative gathering of mining men has ever been called together than that which assembled at Pittsburg, Monday and Tuesday, Oct. 30 and 31, to witness and take part in this first great national demonstration.

The readers of Coal Age are already familiar with the large amount of preliminary work that was required and has been so wisely executed during the past two years following the terrible mine disasters of 1906 in France, Japan and especially in West Virginia. There was need of wise enactment of law that could only be accomplished by the united efforts and action of the various mining interests represented in the large engineering and mining societies, institutes and congresses of the country. Suffice it to say this preliminary work has been done wisely and today the Federal Bureau of Mines is the child of these coöperative interests, born in the hour of necessity and now rapidly attaining its majority and proving its worth by its wisdom and activity. In spite of some little adverse criticism coming naturally as the result of the division of work that must always follow the inauguration of any new department or bureau in either national or State governments, the Bureau of Mines has quietly performed its work and is rapidly gaining the confidence and coöperation of all classes of mining men and mining interests from the engineer and operator to the miner. Coal Age does not hesitate to earnestly commend the work of the bureau to its many readers and asks of them the most hearty coöperation and support, which we feel is already being cordially given.

One of the main features of the present demonstration was a dust explosion in the experimental mine now leased by the Federal Bureau of Mines from the Pittsburg Coal Company for the purpose of making its investigations of mine conditions more real, and for keeping in touch with actual practice. This mine is located at Bruceton, about 13 miles from Pittsburg. Before the Government could enter into or become a party to this contract or lease, it was necessary for Congress to pass an enactment with the approval of the Secretary of the Interior, which was done shortly after the creation of the Federal Bureau of Mines. The act of Congress, we understand, carried an appropriation of $450,000, which was thus placed at the command of the newly created bureau, for its allotment to the various branches of the work now in its charge. Through this allotment by the Bureau of Mines, we believe a fund of $65,000 became available for the equipment and work of the experimental mine at Bruceton.

Availing itself of the generous offer and the hearty coöperation of the Pittsburg Coal Company, the Mining Bureau was not slow to contract for the lease for one year of the tract of coal at Bruceton where the present experimental mine was opened about August, or September, 1910. The Government cannot enter a contract for a period of time greater than one year; but the Bureau of Mines, we understand, has been assured verbally of the willingness of the Pittsburg Coal Company to extend its lease of the mine at the expiration of the time named, should an extension be desired by the bureau.

By the terms of the agreement, the mine was opened according to plans approved by the Pittsburg Coal Company. This was necessary in order that the coal company might operate the mine for its own purposes at any later time when the bureau might wish to abandon its investigations along this line. During the period of practically twelve months in which the bureau has been pushing its work of investigation at Bruceton, the mine has been opened, the necessary surface buildings erected, much concrete masonry put in at the drift mouth and in portions of the mine entries where it was necessary to establish recording stations for holding the various instruments used to indictate the pressures, velocities, temperatures, etc., resulting from a mine explosion. In this period of twelve months the main entry and air course have been driven practically 750 ft. into the hill.

Ventilation of the Mine

Ventilation was at first secured by the erection of a small Sirocco fan, 36 in. in diameter and 20 in. wide, at a point near the mouth of the drift air-course. This fan furnished an air-current of about 4000 cu.ft. per minute; its position, however, was later changed to better suit the purpose of the tests, to its present position in the mouth of the steel tubes or second opening. In this latter position, the fan is run as a blower. The air-current is taken in through the steel tubes

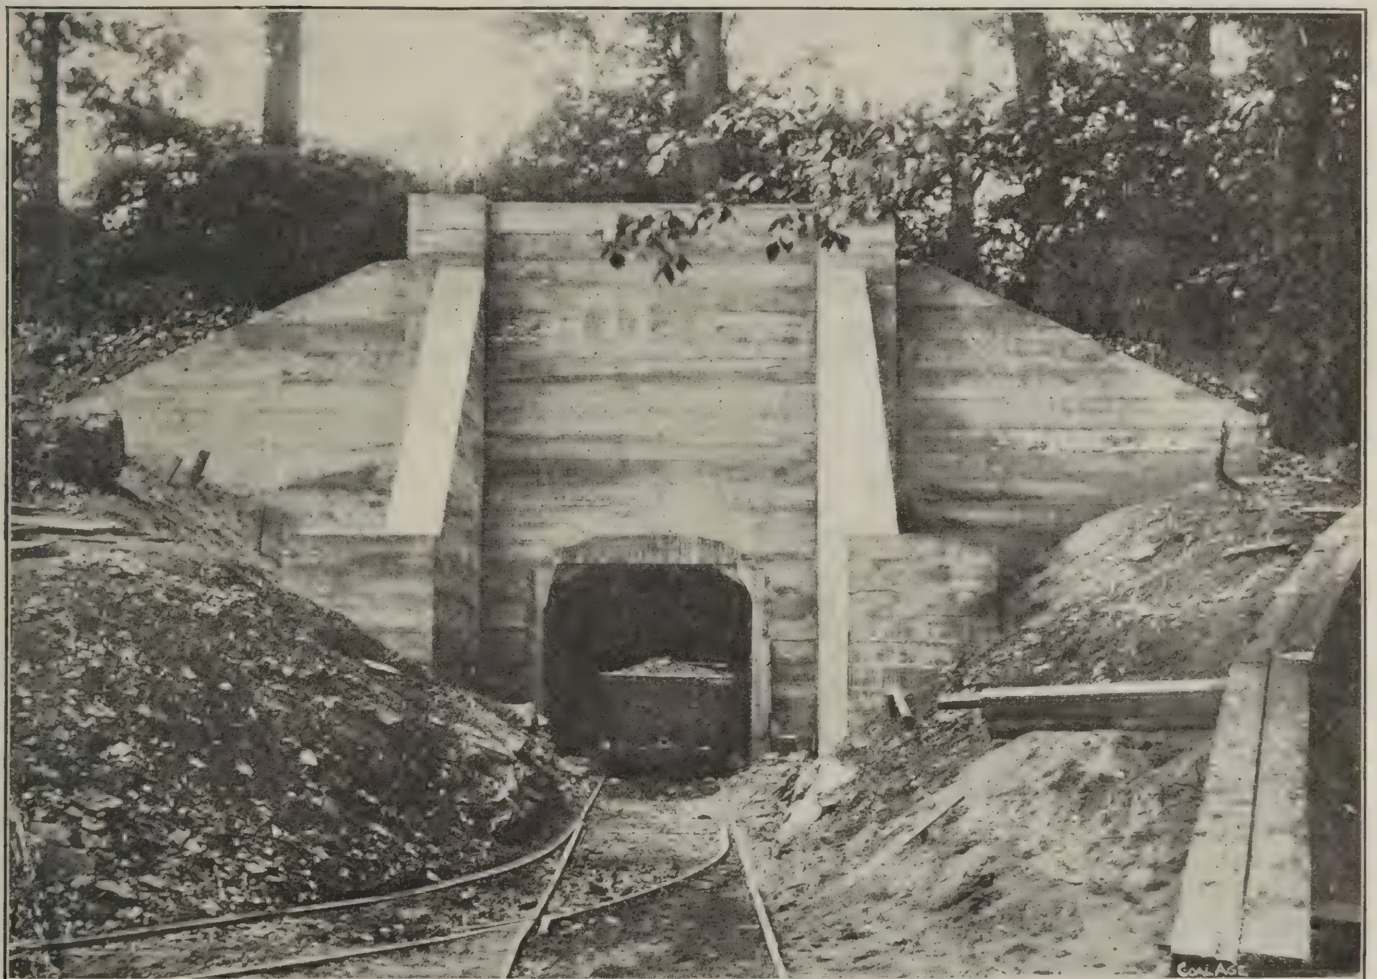
and conducted to the last crosscut between the drift entry and air course, about 60 ft. from the face of these entries.

Location of Shots to Explode Mine

It was in the face of this drift heading that the shots were located, which were, by their explosion, to fire the dust that was scattered on shelves arranged along the ribs the entire length of the entry or drift. These holes were bored straight into the face of the solid coal, from 3 to 4 ft. in depth. Each hole had a diameter sufficient to contain a piece of 1½-in. iron pipe, which was closed at one end with a wooden plug and filled with about 2 lb. of black blasting powder and inserted into the hole bored in the coal after which the hole was tamped with 6 in. of clay. An electric fuse was used to fire the charge.

The Purpose of the Experiment

The purpose of this experiment was to prove or disprove the theory that simple coal dust in a finely divided state would explode under certain favorable conditions without any gas being present. The mine at Bruceton was entirely free from gas, none having been found in the frequent careful tests that were made to discover gas. The mine was therefore well adapted for the purpose in view. In order to insure the success of the demonstration that took place Oct. 30, a trial explosion was arranged for Tuesday, Oct. 24. The results of this trial exceeded all the expectations of those in charge and served as a guide for future experiments. The roar of the explosion and the accompanying blast of flame issuing from the mine openings was described by those who witnessed the experiment as terrific. After this trial the mine was again put in order and prepared for the later demonstration.



The Main or Right Portal of Government Experimental Mine, Bruceton, Penn.

A Dust Explosion Demonstrated

Little, if any, change was made in the amount of dust used and the charge of powder required to produce its explosion; these amounts had been well calculated in the first trial experiment. About ½ ton of dust was used in the entire length of entries, or an average of 1 lb. of dust per lineal foot of entry in the main drift, and ½ lb. per lineal foot in a portion of the intake airway. This dust is to be prepared at the mine by crushing and grinding the coal and passing the same through a 100-mesh screen. The result is a fine impalpable powder that is readily blown from the shelves on which it is placed, by the force of the blast.

Inspection of the Mine

Previous to the explosion the visitors were allowed to pass through the mine, entering at the drift mouth and passing in through the main heading, which was the return airway, to the face and then out along the intake airway and through the steel tube to the surface. It is estimated that 1231 persons entered and inspected the interior of the mine.

It had been expected that only those directly interested in and acquainted with mines would go underground, but in compliance with the popular desire to see all there was to be seen, no one was denied entrance. This inspection of the workings exhausted much valuable time and it was long after the time set for the explosion when the first attempt was made to fire the mine.

Preparing for the Blast

After everyone had returned to the surface and before the blast could be fired, it was necessary to remove the line of incandescent lamps that were used to light the entries, and to make the electric connections at the face of the heading. When this was done, the first attempt was made to explode the mine, shortly before 5 o'clock. Three pistol shots were fired, announcing that all was

in readiness and that the explosion would soon take place. A small six- or eight-volt blasting battery was used, but the blast failed to explode. The officials in charge were wholly at a loss to understand the reason for the failure. No time was to be lost, however, and after a hurried consultation, the wires were disconnected and men sent into the mine to ascertain the cause, and, if possible, remedy the trouble.

The Second Attempt Failed

A half-hour later, three pistol shots told the waiting throng that all was ready for a second trial. The expectancy of the next few moments can better be imagined than described. The gathering darkness and the drizzling rain, which had been falling during the afternoon, added much to the unpleasantness and the vexation caused when this second attempt to explode the mine failed.

It was now 5:30 p.m.; the squad of rescue men who had been anxiously waiting for over two hours to take their part in the demonstration and enter the mine immediately after the explosion, were now sent back to their car. Many others gave up in despair and returned to the station, believing there would be no further attempt made by the officials to carry out the program. A large number of the waiting throng, however, still remained, possessed with what seemed to be a forlorn hope that they would yet experience the reward of their patience and witness the longed-for explosion at the mine. In the meantime, the determination of the officials grew with the fast-coming darkness. A new line of wire was run into the mine and connection made with the lead wires of the fuse at the head of the entries. When this was done the full voltage of the electric-light circuit (110 volts) was turned on.

flame, first from the main-drift mouth and a second later from the steel tube at the second opening. This was accompanied with the sharp rattle of the manhole doors of the steel tube as they were

Timbered Mine Entry — Concrete Mine Gallery — Timbered Entry Concreted

wise about 50 ft. on each side of the opening and reached an estimated hight of 100 ft. in the air, rolling backward from the tunnels in such volume and fury as to thoroughly alarm the crowd of spectators on the hillside above. These observers fled precipitately in all directions.

The Explosion

The effect was magical. The air was suddenly rent with a thunderous roar and the heavens illuminated with a fiery glare that for a few moments sent terror to the hearts of those still waiting on the hillside. Practically simultaneously with the roar underground there was a burst of

successively blown open by the force of the blast, the sound much resembling the roll of a drum.

The scene, with its surroundings of tall forest trees, the deep ravine and the hillside, was spectacular in the extreme. The flame bursting from the mouth of the two openings of the mine spread side-

spectators on the hillside above. These observers fled precipitately in all directions. The explosion lasted but a few seconds, however, and all was again wrapped in darkness now blacker than before, owing to the dense volumes of smoke that poured from the mine openings. The flame in many places had

ignited dead leaves of the tall trees, which, but for their wet condition, might have caused a more serious conflagration. The air for a brief period of time was filled with falling débris, soot and burning leaves. A mine car containing some 500 lb. of gravel, standing about 40 ft. in front of and in line with the mine drift, was blown nearly 200 ft. across the ravine, while another car loaded with rock was moved some 20 ft. and turned partly around. The event was certainly an important object lesson that cannot but prove of lasting benefit to all who were privileged to witness the scene. The Bureau of Mines is to be congratulated on the result of this part of the first national safety exhibit.

Motors Shielded Against Gas

Legal rules in some countries require that electric motors installed in gaseous mines shall be constructed or mounted so that the sparks which they may produce will not cause explosion.

A requirement that the construction of the motor shall afford protection against gas does not mean that it shall prevent

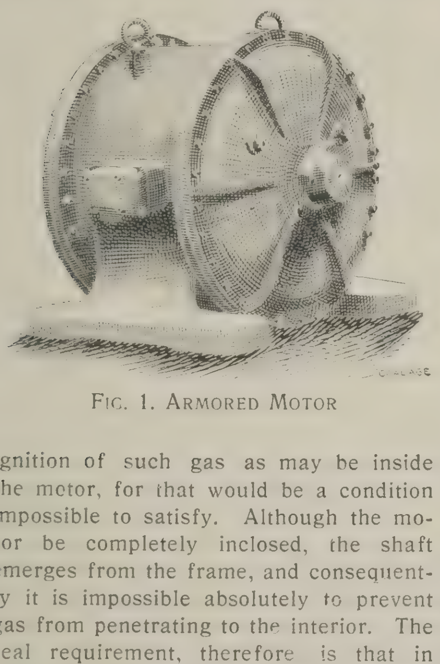

FIG. 1. ARMORED MOTOR

ignition of such gas as may be inside the motor, for that would be a condition impossible to satisfy. Although the motor be completely inclosed, the shaft emerges from the frame, and consequently it is impossible absolutely to prevent gas from penetrating to the interior. The real requirement, therefore is that in case an explosion occurs inside, it shall not be propagated to the outside.

As regards the protection of motors against gas, great importance may be attached to the experiments which took place from 1903 to 1905 in the mines of Gelsenkirchen under the auspices of the Association of Mining Interests of the district of Dortmund, Germany, at the expense of the mining fund of Westphalia in coöperation with various manufacturing companies, and under the direction of the assessor of mines, Mr. Beyling. These experiments showed that there existed two methods of constructing motors guarded against gas. These two methods have been employed with success.

The Two Methods

The first method consists in completely armoring the motor and constructing it so solidly that it will resist the pressure in case an explosion occurs inside of it. Fig. 1 represents a motor of this sort completely armored.

The second method is to let the gases of the explosion issue, but so to cool them that they cannot carry the fire to the surrounding atmosphere. For this purpose is provided a casing for the motor with protecting rings composed of numerous annular pieces of sheet metal placed about half a millimeter apart. The explosion gases pass radially through the rings and are so cooled by the surfaces of the plates, that it is impossible for them to communicate the fire to the surrounding atmosphere. The effect is analogous to that of the wire gauze in the Davy safety lamp.

The frame with its rings and sheet-metal sheathing entirely surrounds either the whole motor, Fig. 2, or only those parts where sparks may be produced during service. In the latter case, where half armored or open motors are used, the

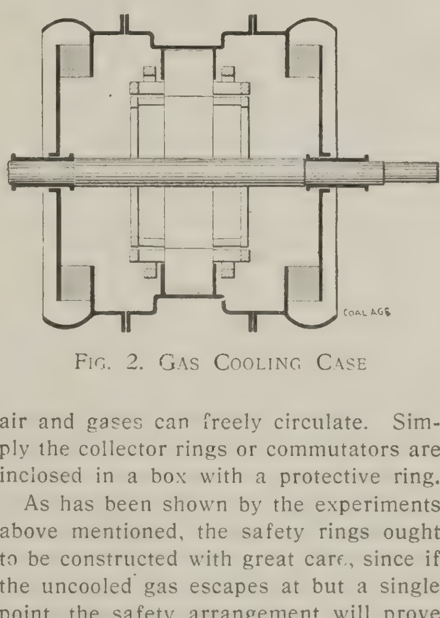

FIG. 2. GAS COOLING CASE

air and gases can freely circulate. Simply the collector rings or commutators are inclosed in a box with a protective ring.

As has been shown by the experiments above mentioned, the safety rings ought to be constructed with great care, since if the uncooled gas escapes at but a single point, the safety arrangement will prove unavailing. The same danger would exist where there was some grounding in the frame of the motor.

It is highly important that motors intended for gassy mines shall, before delivery, be tested most carefully under all the conditions to which they will be subjected after installation.

NOTE—From *L'Echo des Mines et de la Metallurgie*, Paris.

Be careful not to oppose respiration on the part of an asphyxiated person about to recover under treatment. Do not compress his lungs when he desires to inflate them. If the respirations are long apart, carefully continue the bellows-blowing action between natural respirations.

First Aid in Accidents

The following is a timely excerpt from the circular No. 110, on, "First Aid to the Injured," issued by Johnson & Johnson:

The greatest danger to wounds from accidents is due to contamination with foreign substances, not always visible, but far reaching in effect. Certain invisible irritating matter (germs) quickly find lodgment in any wound by transference from the air, the clothing, the skin; in fact, from anything that may come in contact with it. In consequence of such contamination, blood poisoning, gangrene, inflammation, fever, erysipelas and a train of complications are liable to follow any wound.

Small scratches and pricks, when not properly cared for, may result in inflammation and the formation of gatherings or abscesses, which will disable a person for a considerable time or cause the loss of a limb or even endanger life itself.

The necessity and value of prompt and efficient first aid in injuries needs no comment. During the war with Spain, in the Philippine campaigns and in the Russian-Japanese war it has been established that, by the prompt application of first-aid dressings, the loss of life and limb has been reduced to the lowest ratio in the whole history of warfare.

The modern practice of surgery requires that the dressings applied to a wound shall not only look clean, but shall be surgically clean (that is, aseptic), free from surgical dirt.

The application of the principles involved, has saved many an idle day, soothed untold suffering and even saved millions of lives. From the surgeon's standpoint, a piece of spotless linen may be a filthy rag; he does not judge from the looks but by his knowledge of the effects.

Watering Dusty Entries

A recent English invention for watering dusty roads in coal mines is described as follows: A tub or tank is mounted on an ordinary mine-car frame in such a way as to leave, below the tank and above the frame, an open space, in which revolves an iron saucer-shaped disk with four vanes across its face. This disk or turbine rotates rapidly in a horizontal plane through the action of an endless chain driven by the wheels of the mine car. Water flows through a valve in the bottom of the tank, onto the turbine wheel below, and by its rotation is spread outward and upward, the flow being regulated by the valve. This latter may be of either the lever or screw type, the former permitting more rapid adjustment. The turbine wheel may be thrown out of gear at will by a lever which is controlled by the man in charge.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

A miner recently lost his life from suffocation by natural gases. He went past a fence and past a danger sign into a drift, which he knew contained inflammable gas, in order to obtain a shovel which had been left in the drift several days before. The lesson is clear.

Remember that a little dirt adhering to electric mine machinery, a loose terminal wire, a poorly covered joint or careless cable insulation has often caused, and may at any moment cause, death. Careful investigations have shown that most mine accidents, due to electricity, are the result of want of care.

When the different coal-mining States demand an oral and written examination of all mine foremen, and issue certificates to the same before they are allowed to hold positions, and when the State delegates certain police powers to men who successfully pass such examinations, then and not until then will the mine laws be enforced, the death rate materially reduced and property conserved.

According to official reports more than half of the deaths due to the underground accidents in the Nottingham section of England are caused by falling roof; and this after every effort has been made to secure systematic timbering. The various causes of fatalities in coal mines are stated to be in about the following percentages: Falls of roof, 57.8; haulage, 22.6; shafts, 8.8; other causes, 10.8.

When about to institute first-aid instruction work in a colliery, let the first class consist of the bosses, superintendents and the heads of departments; then form classes among the miners. In this way all classes of employees will come in touch with the work, and in case of serious accident there will be a better understanding and more cordial coöperation among such men as may happen to be in the mine at the time the accident occurs.

A competent impartial State Mining Board, free from politics and composed of the most competent of specialists, would do much to prevent accidents, save life and conserve natural resources. To such a board the law should compel all companies to submit their plans as to surface buildings, underground workings, methods of mining and plan of ventilation before mining operations could begin. Such a board should be invested with the power to reject or approve plans submitted to them; thus only such plans as meet the approval of the highest mining authorities of the State could be adopted.

One English writer, in explaining what action should be taken after an explosion occurs, advised among other things that the manager place a notice board in a conspicuous position near the top of the shaft with the following cautions: "Real courage does not consist of being careless of danger, but of being quick to face and disarm it." "Courage without caution is dangerous; caution without courage is contemptible." Would it not be worth while to place such a cautionary signboard in some prominent position near the shaft at once without waiting for an accident to occur. Hundreds of miners have been killed through exercising courage without caution.

It has been demonstrated that sparks will pass between carbon dust, immersed in oil, under pressure of 50 volts, proving that in electrical pressure between metal terminals, the carbon dust which collects forms chains, so that the electricity passes easily from the one to the other. Where metal terminals are exposed, dust held in suspension is gradually deposited, and will be sufficient to establish a short circuit. Assuming a short circuit caused by coal dust at the terminals, and a cloud of dust caused by a traveling trip of cars, Professor Thornton, an electrical expert, concludes it will probably be sufficient to start firing along the roof and perhaps cause an explosion.

The inquiry into the disaster at the Maypole colliery in Lancashire, England, disclosed an apparent lack of any definite line of action to be followed by the firemen and shot lighters when they found parts of the mine dangerously affected by emissions of firedamp, a condition that must arise from time to time in gassy mines, however skilfully the ventilation may be applied. For this reason the commissioners concluded: "An important lesson to be learned from the disaster seems to us to be that an endeavor should be made in mines which make firedamp freely, to fix, if practicable, some standard of ventilation, with the object of lessening both the responsibility and discretion of the under officials."

Mine accidents usually occur at the working faces, which are generally remote from the mine hospital. In such cases, to save time, it has been suggested that a stretcher be made at the face with materials usually found there, such as coats, overcoats or a pair of grain bags, which are commonly used by miners to carry explosives into the mine, and a pair of rails, drills or pipes about 6 ft. long. In case the coats are available, they should be buttoned then turned inside out. Insert the rails or drills lengthwise into the sleeves, thus forming a comfortable stretcher. In case grain bags are used, both corners of the bottom should be cut off so as to permit the improvised handles to pass through. The bags placed lengthwise will make a good stretcher.

In organizing the rescue station at the Kleophas mine, in Upper Silesia, the management has arranged that, both night and day, six fully qualified men are always at the surface, and ready for immediate action. Of the three parties of six men each, the first is employed on the day shift on the surface, the second on the day shift in the mine, and the third on the night shift on the surface. The parties regularly change shifts and work both on the surface and underground. In this way they do not lose their knowledge of underground work. For rescue work to be most effective, there should always be a corps "ready at call" on the surface. This arrangement of shifts should be observed by all. If all the men were below they would be helpless in case of disaster.

At the conclusion of the inquiry into the Whitehaven explosion (Cumberland, Eng.), the jury recommended: "That the finding of gas in working places should be more generally noted and reported in writing; that the ventilation be more adequate; that a system of watering the main roads by means of a spray be brought into operation; that a special rule be made providing that no lighted lamp should be placed on the ground of the working place while the mining of coal is being proceeded with; that workmen on being given their working lamps should be supplied with a tally having numbers corresponding with those of the lamps; that the doors of the return airways should have special keys provided for the opening of the doors on the return side of the airway; that special attention should be given to training in ambulance work and necessary appliances; that strict observance of the special rules should be enforced on all workmen and officials."

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Our circulation for October, 1911, averaged 5330 copies per issue.

Of this issue we will print 6000 copies. No copies sent free regularly. No back numbers. Figures represent live, net circulation.

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

Contents

COAL AGE

The Pittsburg Arsenal

It appears a fitting time, now that so many mining men are gathered at the National Mine Safety Demonstration, to call attention to the undesirable quarters in which the Bureau of Mines performs its valuable work, and to express the fear that the significance of the bureau may be lost sight of by ourselves and our foreign visitors when we and they view the bare and meager buildings with which the operations of the bureau are surrounded.

Compared with our university and college buildings, with the offices of our larger corporations, with, one might add, the high-school buildings of our larger towns, the arsenal at Pittsburg, the home of our Bureau of Mines, looks squalid and commonplace.

There are questioners who wonder whether our universities and colleges, which teach the civil, mining and mechanical arts, do well to surround themselves with so much grandeur, training the young man to associate his profession with a luxury, with which in practice he must almost invariably dispense. This contrast results in his disillusionment and renders him, in a degree, at least, unfit for the vicissitudes of life he must later experience. But while this argument has a certain degree of truth for the raw product passing the collegiate mill, it cannot have for the finished product, mellowed by practical training and experienced hardship, such as finds home for research in the Bureau of Mines.

Uninviting indeed are the gloomy buildings offered as laboratories and offices to these engineers whose salaries are not so large as will compensate them for the inconveniences they must endure. Will an uninviting home for the bureau on an inferior street in an unfrequented part of the city, away from library and technical school, do the work that would be done, and enlist the men who would be enlisted if the investigations were carried on amid pleasanter surroundings?

It is true the lines of endeavor of the earnest men of the bureau are laid toward the accomplishment of more and more research in return for the penurious gifts of a nation, which is but tardily responsive to the needs of the work and the excellence of the results already obtained. Other bureaus, which have deserved no more from the public, have had magnificently appointed headquarters constructed for them. The nation should do no less for the Bureau of Mines, constructing a wing or central building for immediate needs only, and paying attention to the architectural possibilities of future additions. The plant should be located where it will be an adornment to Pittsburg, and a complement to its present dedications to knowledge, visible to the general public and ready of access to the valuable technical library stored within the walls of the Carnegie Institute.

The Laws of Safety

The codes of mining laws are the monuments of our care for life. Some are defective; some are reasonably well alined with our present knowledge; what they are, what they are not, is due to the operator and the miner in all States where mining is an important industry. True it is that both parties attack certain provisions as too onerous to one class or another, but if the proposed enactment is well grounded, the sentiment of the unprotesting carries the provision through. Although the general sentiment of the operators and miners is for safety, we sometimes feel abashed at the narrow arguments for laxity urged by the few. The impulse is well nigh universal that safety must ever hold first place.

This feeling was abundantly evidenced in the recent meet at Pittsburg. Operators and squads of men came from all over the United States to study safety and to exemplify it, willing to travel further to obtain such knowledge than they have so far shown themselves willing to travel for a broadening of their economic training. We cannot but feel proud that the knowledge which means money is less appreciated than the knowledge which means life.

The laws of each State are the laws framed by the mining industry. It made them, passed them and, as a whole, approves them, while they in turn approve the industry. These same laws have been created in accordance with the spirit of the age. The mining fraternity does not regard them as mere enactments, bristling with penalties, nor as disagreeable restraints, but rather as the outcome of the industry's better self. It is to be hoped ever that the law will be fulfilled, not in "the letter that killeth, but in the spirit that giveth life."

The Scranton Mine Cave Commission

There is a natural regret that the Scranton mine-cave commission and the engineers it engaged came to no startlingly new conclusions and gave no mollifying assurances to the public that security and absolute roof support could be obtained at small cost.

But it is no small misfortune when a city of 130,000 inhabitants, with buildings of great artistic merit (for indeed Scranton has some which for pure beauty are seldom excelled) rests upon a tottering series of crumbing walls, aggregating over 65 ft. in hight, and so arranged that the full strength of these is not obtained; walls that are yet to be removed wherever possible and for which no provision for replacement has been hitherto considered.

So sore an ill can be assuaged by no inexpensive cure-all. The city owes the commission a debt for bluntly acknowledging the magnitude of the peril and for urging on the citizens and operating companies that they provide adequate means, at the needful expense, for the prolongation of the life of the city they live in. It would have been criminal for the engineers hoping to mollify the public and the coal companies to have made an evasive or inadequate recommendation and a report filled with weakling deceits.

The hope of a gratifying report might have been held out, had the structure been in the form of a dome or an arch. Then the load could have been carried to certain limited areas, and fracture might have been prevented by provisions against excessive settlement at the inclosing walls or wall-like piers on which the dome or arch, respectively, rested. Or again, had the measures been, as they are in the case considered, relatively flat, and had, as is not the case, but one bed of coal been worked, then any attempt of the structure to fail as a beam, would have been prevented by the thrusts or horizontal pressures set up by the binding of the strata overlying the coal as they endeavored to crowd into the space between the supports. These thrusts, combined with downward loading, would create surfaces of pressure whereby the flat roof would be transformed into dynamic semblance to an arch or dome and the internal strains with resultant internal falls would probably create a real culvert or cupola with filled spandrels.

Such a roof might settle in one large area, as a vast unit, making the bulk of the city safe, even had the very supports of the arch been cautiously removed, providing care had been taken to secure the arch in position against side pressure, for though the thrusts in an arch, when it is high, are not considerable or large compared with the vertical loading, yet it is important that they be taken care of, for a structure of that kind, when it spreads at the supports is considerably weakened.

But with several beds worked and with intervals between the beds thin, the result can only be a series of superposed arches too shallow for self-sustenance, and for which there is no cure but filling, complete or incomplete. The method, proposed by the commission, is to provide a series of flushed foundations at the corners of city blocks, which will provide for the support of whole congeries of buildings, which, when shrinkage comes, will involve them altogether and let them down without mutual strain.

These blocks of buildings will have foundations spaced like those of the Eiffel tower and in a dynamic sense, will rest as if on a series of arches parabolically curved in three dimensions, as in that unique structure, yet with all the curves concave as viewed from below. The arches will be not the less truly entitled to that name, because they may happen not to be so shaped. They may continue to stand up like flat arches, such as are commonly used to span house openings, or they may break up and reshape themselves into the forms of quasi-Roman, or of quasi-ellipsoidal spans.

That it is better to support the street corners than the blocks themselves (unless indeed the filling is almost continuous) is seen when one reflects that one flushed pillar may shrink more than another and the strains resulting from the shrinkage would be likely to rend an overlying building, wall from wall.

The suggestion of filling the Dunmore beds is not unreasonable. It must be remembered that they are thin, none, over any large area, exceeding 4 ft., and a great deal of rock will need shooting in any event for gangways and chamberways, and where the roof is weak, there may be more roof fall than there is room adequate for stowage. The rock in the anthracite region is peculiar in that it stands air well and when piled in chocks, its first set under the final load is its last. There is no further settling as a result of its disintegration, or of the deterioration of the surfaces on which it rests.

The Value of Scrap

Many mine managers have the price of a coveted and necessary piece of equipment lying around their property in the form of scrap. The wornout car wheels and axles, gears, chain links and sprockets, old rails, old pipe, old rope and all the sundry discarded irons and castings which so generously bestrew the ground around some collieries, often represent a tidy sum of money.

Such accumulations of useless and discarded material are, moreover, apt to impart an appearance of disorder and an impression of waste quite out of proportion to the expense involved in systematically disposing of them. The stranger, be he merely an inquisitive visitor or the company's largest stockholder, judges, to a great extent, by externals. It is always well to avoid the appearance of evil. Scrap, left at random about a plant, has a decidedly negative value; it is worth a good deal to be rid of it.

It may be that the things which go to make up the colliery junk heap are looked upon by a wary and acquisitive foreman as possible saviors in some time of need, but any such expected value is seldom realized. When the emergency arises, it usually develops that nothing in all the varied assortment will quite fill the bill. Repair parts are one thing and scrap decidedly another. The former should be sound and serviceable, carefully stored and cared for. The latter is worth, perhaps, half a cent per pound.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Interesting Questions

To Prevent Accident, Loading Coal

Ques.—A large percentage of mine accidents is caused by miners persisting in loading coal where the roof is unsafe. What rule would you adopt to prevent this condition and reduce the number of accidents therefrom?

Ans.—An invariable rule should be adopted that no coal shall be loaded at the face until after the miner has carefully examined the roof and coal face, in his place, and either taken down or timbered securely all loose coal, slate or rock. This rule can generally be enforced by the penalty of a lost turn if the rule is violated. Every miner should be held responsible for the timbering of his own place; and the mine foreman and his assistants should see that such timbering is properly and promptly done.

Safety in Blasting in Mines

Ques.—Describe briefly the comparative merits of firing shots in mines by means of fuel, squibs and electricity, in respect to safety.

Ans.—When shots are fired by the common single-tape or double-tape fuse the length of the fuse can be regulated so as to give the person who fires the shot plenty of time to retire to a place of safety. This cannot be done in the use of squibs.

Indeed when squibs are used, the miner is often tempted to break off or shorten the end of the match of the squib, or untwist the end so as to hasten the explosion and at the same time to avoid the danger of misfire by the match going out after it has once been lighted. At times, the miner dips the match of the squib in coal oil for the same purpose. All of these practices are extremely dangerous, often causing the shot to explode before the miner has reached a place of safety. It frequently happens that, in the use of fuse for blasting, an unscrupulous miner, when he has overcharged a hole and is somewhat doubtful in regard to the safety of the shot, will cut a long length of fuse to enable himself to get well out of harm's way before the shot explodes. He does this, at times, with an entire disregard of the safety of his fellow workers. In the use of fuse a good quality of double-tape fuse should be employed. Single-tape fuse should never be used in mining, owing to the danger of the fuse being injured in the rough work attending the tamping of the hole, and in the rough handling which is general in mining work.

In the use of electricity for blasting there is always less danger of misfires, and the danger from hangfires is extremely slight, although both of these occur at times. There is, also, in the use of electricity, less danger of a premature blast, resulting in the miner being caught before he has reached a place of safety. In electrical firing, the battery should always be kept under lock and key and be in the charge of one competent person who is to fire the shot. The lead wires used to conduct the electric current into the chamber or room are never connected to the battery until all connections have been made at the working face where the shot is located. After the workmen have retired from the place the shotfirer brings out his battery and connects it with the lead wires; he then applies the handle and operates the battery. Should the shot fail to explode in this method of firing, after two or more trials, the shotfirer removes the handle from the battery, disconnects the wires and proceeds, after the space of a few minutes, to investigate the cause. In electric firing it is never safe to approach a shot that has missed fire before the elapse of from five to ten minutes, at least; and more than this time should be allowed if all possible danger from accident is to be avoided.

Hangfires in Blasting with Fuse

Ques.—Explain what conditions may cause a shot to hangfire where a fuse is used for blasting in mines.

Ans.—In firing blasts with fuse a shot may hang fire for an indefinite period, lasting from a few minutes to several hours, according to the kind and condition of the fuse in the hole. Perhaps the most common cause of a shot's hanging fire is due to a small piece of coal or rock being jammed into or against the fuse in tamping, whereby the train of powder is broken. The outer covering of the fuse then smolders till it at length reaches and ignites the powder beyond the break. Or the fuse may be damaged before it is placed in the hole, and give the same results as described above. Sometimes the powder of the fuse becomes damp and burns slowly and intermittently, or the fuse may be drawn out of the charge and only ignite the paper wad that some miners use over the powder; the paper smolders for a time and finally ignites the charge. In blasting with fuse, it is never safe to return to the face when a shot has failed to explode. The miner should go home and leave the investigation of the trouble for the next day. It is the only safe rule.

Safety Arrangements, Mule Haulage

Ques.—What arrangements should be made, in mule haulage, to insure the safety of drivers and all persons employed in the mine?

Ans.—Strict regulations should be enforced relating to the movement of cars, and especially providing for the meeting places of drivers on single-track roads. No cars must be left on haulage roads, or extending from the mouths of rooms where they would interfere with haulage on the main track, or in a position where they might become loose and run down grade. No car must be taken down a grade where sprags are required without the driver first seeing that such sprags are properly adjusted. A door must not be located at the foot of a sharp grade. Refuge holes must be provided at all doors for the protection of trappers, where trappers are employed; and at proper intervals on all haulage roads used as travelingways, except where such roads are wide enough to allow safe passage for men on the side of the track.

Safety Arrangements, Shafts and Slopes

Ques.—Mention briefly the various arrangements and appliances for safety, employed at shafts and slopes.

Ans.—The top of all shafts and steep slopes, as well as all landings, should be protected by suitable gates to prevent persons falling into the shaft or down the slope. Safety blocks should be placed on all tracks leading to the shaft or slope, on every landing, to prevent mine cars running or being pushed into the shaft or slope. All cages should be provided with sufficient hoods, safety catches and bridal chains; and where men are to be hoisted suitable guards should be used on each end of the cage. The last car of a trip being hauled up a slope of moderate inclination, should always be provided with a good drag-bar or "dog" to prevent any or all the cars running back down the slope, in case the rope or a coupling should break.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Leasing System for the Alaskan Coal Lands

Secretary Fisher, of the Department of the Interior, has declared himself positively with reference to the policy he intends to recommend to Congress this winter in connection with coal mining in Alaska. Mr. Fisher's statement has been received with unusual interest in this city because of the influential character of his recommendations, particularly in view of his recent visit to Alaska. As already forecast, Mr. Fisher takes the view that the value of the Alaska coal has been greatly exaggerated. There are, he says, great quantities of lignite and low-grade bituminous coal in several parts of the Territory, but there are only two known fields of high-grade coal in Alaska, the Bering River field and the Matanuska field, both of which contain anthracite and high-grade bituminous coal.

"My own judgment," says Secretary Fisher, "is that the present market for Alaskan coal is limited and uncertain, but that the demand will rapidly increase as the country is developed." Whatever may be the value or extent of the demand, Mr. Fisher thinks that the time has past when public mineral lands should be allowed to go into private ownership in fee simple. He, therefore, urges the leasing system, saying, "Taking all our principal coal-mining States, the census figures for 1909 show that out of a total of 6,900,000 acres of coal lands under operation more than 2,000,000 acres, or 30 per cent. of the whole, were in 1909 operated under a system of private leases. It is, therefore, substantially correct to say that, whether we like it or not, the choice is not as to whether we shall mine our coal on the leasehold system, but whether we shall mine it under leases from private owners or from the Government direct."

Conditions and Terms of Leases

"That the customer has everything to gain under the Government leasehold must be apparent because the Government can make its royalties as little as it chooses and it has no invested capital and no unearned increment on which to pay returns. Opposition is to be expected only from those who wish to secure our coal lands for stock-jobbing or speculative purposes or so that they may make a greater profit than is essential to secure immediate development. Indeed, immediate development can be assured only under the leasehold system. Without it there is no reason why private individuals should not secure the property and hold it out of development until they can take advantage of the increasing demands of the future."

"Expedients could be adopted in the effort to enforce development by requiring the purchaser to mine a certain amount of coal or to expend a certain amount of money in developing the land under pain of forfeiting his title to the Government, but this, after all, is only a crude and awkward device for securing what can be far more effectually secured by means of a lease. Regulation of this sort would be a new departure in either State or Federal administration. It would raise fundamental questions of public policy about which differences of opinion exist, which are as yet uncompromising. It would doubtless prevent any early action by Congress."

"Under these conditions it would seem a sufficient undertaking to inaugurate a new system of tenure, without imposing upon Alaska the additional difficulties of the administration of a hitherto untried attempt to settle by public regulation what would constitute a reasonable profit for the miner, the wholesaler and the retailer of coal."

Rates on Coke to Chicago

An application has been filed with the Commerce Court by the Anaconda Copper Mining Company and the Boston & Montana Consolidated Copper and Silver Mining Company to review the decision of the Interstate Commerce Commission in the case involving the rates on coke from West Virginia and Pennsylvania to Chicago and Chicago junctions.

Previous to the present year the railroads had in effect a rate on coke of \$2.65 for smelting and \$2.35 for iron furnaces. The copper companies desired to collect reparation on shipments made under the \$2.65 rate during five years, which, it is said, would have amounted to \$18,286. The commission decided that the railroads should have but one rate on coke between these points, but refused to take any action relating to reparation. The single rate was to go into effect Dec. 31, 1910.

William A. Glasgow, Jr., representing the copper people, recently filed the petition with the court to review the decision of the commission and to award the complainants the reparation demanded.

Alabama

Birmingham—The Mulga mine, which is the property of the Birmingham Coal and Iron Company, is now one of the best equipped mines in the State. The daily output is averaging 1100 tons and the 400 men employed there are working full time.

In a report issued Oct. 28, the Alabama State mine inspector states that there are now 242 coal mines in the Birmingham district, of which number, 21 are idle at present. There are over 20,000 miners at work in this field and 6000 more could be employed under existing conditions, according to the report.

The Coosa Valley company has been organized at Atlanta, Ga., with a capital of \$2,000,000, to develop coal and mineral lands in northern Alabama.

Colorado

Oak Creek—The Routt County bank of Oak Creek and the various business houses on a recent pay day cashed checks totaling \$75,000. This is the largest amount paid out in any one month in the history of the Routt county coalfields, but it is said that each succeeding month will show still further increase.

Cañon City—The 150 miners of the Bear Gulch mine of the Colorado Fuel and Iron Company, went on strike recently, as a result of the inauguration of the basket scale in paying for the coal.

Pueblo—This city is very much incensed over a recent increase of 25c. per ton in the retail price of coal and the project of a municipally operated coal mine is being discussed.

Illinois

Duquoin—Despite the discouraging conditions which exist in the southern Illinois coalfields as a result of the railroad strike, unusual activity is being manifested by the coal interests in sinking new mines.

Several new shafts are now being sunk in Williamson and Perry counties. A company of Tamoroa business men has secured the Kimsey farm of several thousand acres, northeast of this city, and the work of sinking a large mine is under way.

The Zeigler District Coal Company of Chicago, which owns a large mine at Christopher, has purchased several thousand acres of untouched coal land near Mulkeytown, east of this city, and will sink a shaft.

Indiana

Indianapolis—President White, of the International Mine Workers' Union, has sustained the officials of the local unions in calling a special session of the organization to pass upon the weekly payday proposition. President White held that there was no evidence that the local officers acted hastily in calling the convention, and that the proceedings throughout were fair and legal. This means that the semi-monthly payday will stand until the present contract between the miners and operators expires next April.

Iowa

Newton—A 3-ft. vein of coal was discovered recently several miles south of here. It lies at a depth of 34 ft., under 17 ft. of rock.

Des Moines—Amended articles for the Lucas Coal and Supply Company, of Lucas, capital stock, $250,000, have been filed.

Kentucky

Middlesboro—The Interstate Coal Company has purchased 800 acres of coal land in Knox county for $50,000, and will develop mines.

Louisville—The Kentucky and Indiana Terminal railway has awarded a contract to the Roberts & Schaefer Company, Chicago, for a 500 tons capacity coaling station to be built at Louisville.

Montana

Havre—The Havre Electric Light Company is opening up a coal mine 3 miles north of town. The vein is 3 to 4 ft. thick, at a depth of 150 ft. and the coal is reported to be of excellent quality.

Ohio

Columbus—For some time past a syndicate which has acquired large areas of land in Richland and Jackson townships, Vinton county, has been exploring for coal and it is said that large areas have been found, among them a 53-in. vein. Practically every acre of land in the two townships is under either option or lease. The Columbus & Southern railway, it is said, has passed into the control of the same interests, and will be extended to give an outlet for the coal.

The consolidation of the big coal interests of eastern Ohio, which was reported some time ago as under way, has been practically completed, according to recent information. The combination will include the five largest operating companies in Jefferson, Belmont and Harrison counties, and will have a property valuation estimated at $20,000,000.

The new apparatus purchased by the State, recently was the means of saving from death eight men overcome by gas in the Black Top mine of the Morris Coal Company at Lore City, Guernsey county, according to report made to the State mine inspectors' office.

Pennsylvania

Bituminous

Pittsburg—It is reported that a coal deal between local capitalists and a New York syndicate involving $1,000,000, has been closed. Several thousand acres of coal lands in Forward township, near Elizabeth, in the McKeesport district, are said to have been sold. According to the report, building of tipples and docks will be commenced at once.

The experimental mine of the U. S. Bureau of Mines, at Bruceton, Penn., was the scene of a coal-dust explosion Oct. 24. About 200 lb. of coal dust were purposely ignited by the engineers in charge and from all reports the results exceeded their expectations, considerable damage having been done.

Ohiopyle—It is stated that several mines will be opened up in this vicinity along the extension of the Western Maryland railroad. Recent investigations by this company are reported to have resulted in disclosing something like 10,000 acres of high-grade coal land.

Indiana—With five openings in active use and four more ready for work within a few weeks, the Penn Mary Coal Company, of Heilwood, expects to close the year with its finest record since the opening of the mines.

Anthracite

Scranton—Reorganization and financing of the Peoples Coal Company by its new owners embody plans of exceptional interest to stockholders and investors. A total bond issue of $400,000 is authorized, but only $350,000 is being put out. The capital stock of the company will remain at $100,000.

A recent decision handed down by Judge Garman, of Luzerne county, practically awards to the borough of Forty Fort a tract of coal land valued at $100,000, which is being mined now by the Lehigh Valley Coal Company. The original deed dates back to 1768.

Pottsville—The Kaska William colliery, under the management of the Alliance Coal Company, will be extensively improved and developed. A contract has been awarded to a local firm covering several hundred yards of rock tunnel and this work will be started at once.

Washington

Ellensburg—Orders have been issued by the Northwestern Improvement Company that No. 6 mine, located in Roslyn, is to shut down on Nov. 1 for the winter. This is the largest mine at Roslyn. The order is the result of the company having sufficient coal on hand.

Seattle—A 5-ft. seam of coal was uncovered recently in Thompson Valley, B. C., south of Kamloops, by the grading crew of the Canadian Northern railway. The coal is said to be of commercial quality, and it is expected that the find will result in the immediate opening up of a new field.

West Virginia

Wheeling—W. G. Simpson, receiver for the Gorrell Coal Company, at Pipe Creek, has sold to J. W. Gorrell, the mine and equipment for $131,000. The mine, which contains 1000 acres of No. 8 Pittsburg coal, was appraised at $133,000. It is said Mr. Gorrell will organize a company and operate the mine.

The Consolidation Coal Company has secured the contract for 40,000 tons of steam coal for the Egyptian State Railways. This is the first time the latter company has asked for tenders for American coal.

Canada

Vancouver Island—The Western Fuel Company is opening two new mines. The Canadian Collieries, Ltd., has decided upon development and additions to plant, etc., involving an outlay of about $750,000. One important change will be the development of hydroelectric power as a substitute for the existing power plants at the several mines at Cumberland.

Alberta—Good progress is being made at the Chinook Coal Company's plant. The tipple is complete. The boiler house is under roof and machinery is being installed. Underground development also is being pushed rapidly forward.

Personals

Samuel Stanley has resigned as sales manager of the Jackson-Superior Coal Company, Columbus, Ohio, and is succeeded by E. F. Aylward, of Cleveland.

E. N. Zern, mine superintendent with the H. C. Frick Coke Company and Jamison Coal and Coke Company since 1908, has been appointed assistant professor of coal mining in the University of Pittsburg.

C. B. Wadsworth, chief engineer for W. J. Rainey in the Connellsville coke region for the last 23 years, has resigned his position taking effect Nov. 1, after which he will take a rest at his home in Ravenna, Ohio.

Harry E. Zaring, formerly assistant secretary of the Crucible Steel Company of America, has been elected secretary of the Crucible Coal Company and will assist J. W. Neff, general manager, in the development of the company and its operations.

Harry S. Brady, who for the past two years has been general manager in Ohio for the Pittsburgh Plate Glass Company's coal interests, has left the latter company to become associated with the Cleveland office of the Moreland Coke Company, of Pittsburg.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The coal market, broadly speaking, still continues to show a little improvement as the season advances. While some sections report trade slow and prices sagging, in other districts the demand is urgent with offers of substantial premiums for spot deliveries.

In the extreme East, a genuine shortage of anthracite seems imminent, while bituminous is improving, although still weak in spots. The lake shipments continue unusually heavy, and demand is satisfactory.

Pittsburg reports mines still working 70 to 75 per cent. capacity with the market dull and heavy; however, the recent blowing-in of several furnaces may help the coke industry. The Ohio trade continues good with prices firm. A car shortage is developing on the Chesapeake & Ohio railroad, although it has not reached serious proportions. It is expected the Lakes will remain open till Dec. 1, and with the congestion relieved at the upper end, the shipments are now heavy.

The Middle West market continues dull. The effects of the Illinois Central strike are becoming apparent and it is thought if this trouble is not settled within the next two weeks, the situation will become serious.

Labor troubles and heavy snowfall, with a decided drop in temperature, are making demands in the West urgent. On the Pacific coast the market is normal and supplies adequate.

Boston, Mass.

Anthracite and advancing freights are the features here this week. Rates on hatch loads of bituminous in Reading barges are 75c. from Philadelphia to Boston, instead of 65c., and the supply of barges is so short for anthracite generally that soon we shall be facing a genuine scarcity in all sizes. It is said that during the week ending Oct. 21, not a single Reading tow arrived in Philadelphia, and with the brisk demand now, and the complications almost in sight, there is little prospect of the companies catching up on deliveries. Then, too, a number of buyers in the East are suddenly waking up to the nearness of winter and are crowding their usual sources of supply for immediate shipments. The eastern storage depots for some of the anthracite-producing companies are said to be practically bare of stock and anything like early replenishment is not yet in view. Anthracite within the week has taken a serious turn, serious for those caught with light supplies.

This week, the first of clear weather for some time, was one of heavy water arrivals, both in anthracite and bituminous, but the shortage in tonnage is now so marked, and the season is so far on, that there is likely to be no recession in rates, at least for the rest of 1911. Freights east from New York to the shoaler points about the Penobscot are now firm at $1, where a fortnight ago they were 65 to 75c.

All-rail in bituminous there is no apparent change. Sales agents and operators alike have had so discouraging a year that they are rather diffident over the immediate future. The Southern coals will have to move up considerably before there will be much extra tonnage for Pennsylvania.

Pocahontas and New River prices at Mystic wharf are up, although a rumored sale at $3.75 on the cars is rather discredited; $3.53, however, seems a firm figure, but it should be said that what coal is at the railroad piers is almost exclusively on contract. There is little free coal and there is not likely to be until transportation begins to move again with something like regularity. On an 85c. freight, $3.53 would still be a low price, netting but $2.45 f.o.b., Hampton Roads, or $1.05 at the mines, less commission, although, of course, such sales now are on bottoms chartered some weeks ago.

New York

A very satisfactory demand on contract for the higher-grade steam coals continues to be the feature of the coal business in the New York market. The supply of these grades at the New York piers is more than adequate to the demand, but with the contract movement so good, prices for standard grades while not strong, show no tendency to decline. Inferior steam coals are in oversupply in this market and as there has been considerable of it on demurrage, prices have been made in a number of instances, regardless of the cost of production, to escape further penalties.

The car supply at the mines furnishing this market continues to be satisfactory, but at some of those mines shipping to the West, a scarcity of equipment is beginning to be noticed.

Railroad movement to New York tidewater has been exceptionally good this fall, and that is one reason for the large standing tonnage now at the New York piers.

Prices for steam coals have not changed any this week, and with the exception of the demurrage coal, range about as follows: $2.35 f.o.b. for West Virginia steam coals; $2.55 for ordinary Pennsylvanias; $2.65, fair-grade Pennsylvanias; and $2.75@2.85 for the better grades.

The supply of slack coal seems to have been somewhat reduced, and there is a little more demand for this grade.

Pittsburg

Bituminous—While the lake movement is nearly over, a considerable tonnage will be moved in November. Mine operations have shown no material change thus far, and are between 70 and 75 per cent. of capacity. Prices are unchanged, the ones here quoted being under the nominal market, but subject to occasional further shading: Nut, $1@1.05; mine-run, $1.05@1.10; ¾-in., $1.15@1.20; 1¼-in., $1.25@1.30; slack, 40@50c. per ton at mine, Pittsburg district.

Connellsville Coke—The market continues in its rut. There is no interest in contracts for next year, and the small sales of prompt coke being made are at unchanged prices. Several lots of prompt furnace coke, aggregating perhaps 50 cars, have changed hands in the past week at $1.50, which has been the quotable market for several weeks. One sale for forward delivery is reported within the past week, a lot of 6000 or 7000 tons for November and December delivery, at $1.55, ovens, a fair price at this time of year when prompt coke is $1.50. The movement in foundry coke is light. We quote per net ton, f.o.b. ovens: Prompt furnace, $1.50; contracts over first half (nominal), $1.65@1.75; prompt foundry, $1.80@1.90; contract foundry, $2@2.25.

A second Wickwire furnace at Buffalo went into blast last week and Clinton, in Pittsburg, goes in blast this week, both stacks using tributary Connellsville coke.

The *Courier* reports production in the Connellsville and Lower Connellsville region in the week ending Oct. 21 at 310,-766 tons, an increase of 500 tons, and shipments at 3791 cars to Pittsburg, 4933 cars to points west and 1039 cars to points east, a total of 9763 cars, an increase of 300 cars.

One of the two Zug Island blast furnaces of the Detroit Iron and Steel Com-

pany, at Detroit, Mich., has been regularly in blast, using Connellsville coke. The other stack, which regularly uses byproduct coke, has been out for several months, during which time it has been converted to a "thin-wall" furnace, the lining being made one brick thick and the steel shell being equipped with a water-cooling arrangement.

Philadelphia

There is not the feverish activity in the retail trade that was manifested earlier in the month, and the trade has now settled down to a good strong current of business. There is some difficulty in having orders promptly filled for some of the sizes, but, as a rule, the delays are not serious. Compared with last year, dealers report that their tonnage is considerably ahead, and it looks as though the prediction of a hard winter is beginning to bear fruit in the minds of the prudent householders.

The wholesale trade still continues active as earlier in the month. Careful inquiry shows that none of the sizes are lagging, many of the companies are behind on deliveries, and it has even come to picking up coal from stock, which is rather unusual at this season of the year. The tonnage is reported as showing a very comfortable increase over the preceding year, with no apparent signs of a falling off. The stormy weather prevailing along the coast during the last week has interfered materially with the movement of water coal, and as a consequence there is a large number of cars on hand at tidewater. This condition will, no doubt, change soon, as open weather has been predicted, which will enable vessels to land.

The improvement in the bituminous trade has been very marked during the past week, but the inclement weather has interfered with movement, and while the coal has been sold and is waiting shipment, it is causing the operators considerable anxiety and annoyance, with fear of large demurrage bills. But the fact remains that there is a general improved tone to this branch of the trade, and it looks to be permanent.

Buffalo, N. Y.

There is a steady, though slow, improvement in the soft-coal trade. Dealers and operators express doubt and dissatisfaction with conditions as they see no material change for the better and so are inclined to believe that the increased demand is a mere reflex of the time of the year, and they do not expect any advance in prices until the rush comes after the first of the year, when consumers become afraid that the supply will stop in April on account of labor disputes.

The volume of trade is as large as it was a year ago, so the complaint is all on account of low prices. It takes a very large tonnage to insure a fair profit, so the small jobber is accomplishing very little and as a rule the operators are complaining that they are only paying expenses.

Soft coal is unchanged in price, Pittsburg three-quarter is quoted at $2.50, mine-run at $2.40 and slack at $2, with Allegheny Valley prices from 20 to 30c. lower. There is no stir in coke at $4.25 for best Connellsville foundry, and $3.50 for stock coke. There is a good demand for smithing coal at $4 from Georges Creek, Cumberland. The supply of cannel coal is increasing, but there is demand enough to meet it, at $4.25. Retailers are making a price of $7 for cannel, which they usually sell in small quantities.

The hard-coal movement is large, even for the time of the year, especially by lake. Early in the season it was thought that the record-breaking movement would give way long before this, as the upper lake docks would be full to capacity, but it is now reported that the glut of soft coal is much greater than the hard. Lake shipments of anthracite from this port continue at about 100,000 tons a week.

Cleveland, Ohio

The Lake coal business for this season is practically closed. A large tonnage on cars still remains on track, both at Cleveland and along the Lake Erie points, awaiting boats for loading. This is to be held over at this end and the upper Lake points during the winter.

It is understood that all contracts have been canceled for any further shipments north this season, and the consequence is that the shippers are paying car service on the coal that is now on track, if not reconsigned prior to Dec. 1, which is the time limit given by the railroads. The result is that shippers are using every effort in procuring boats and loading same as fast as the machines can unload the cars.

The domestic trade has taken another spurt in the past week, here as well as in rural districts in Ohio. The approaching cold weather and the expected scarcity of cars, is the natural consequence in this case. It is also noticeable that the steam trade has somewhat improved. Prices, however, in both the domestic and steam trade, have not shown any appreciable advance up to the present time. Dealers are looking forward in the near future for the better prices, which naturally follow when demand increases.

Columbus, Ohio

More favorable weather, in the form of a slight cold snap, caused an increased demand for domestic grades and as a result the entire trade showed a better feeling. Orders for immediate shipment for domestic uses came in fast and the tonnage moved during the past week was much larger than the week previous. Prices are being well maintained at the quotations in the circular of Sept. 1, although there are some complaints of price cutting.

Steam business is running along unchanged. There is a feeling of uncertainty in the manufacturing establishments and they are not taking supplies for the future. The policy followed is to buy only what is needed for immediate wants. Railroads are also using a minimum as the freight movement is still small.

One of the best features of the market is the lake trade, which has regained its activity, and the tonnage is increasing from all Ohio fields that participate in the lake traffic.

The congestion of the docks of the upper lake ports is passing away and the movement to the interior is better. There is nothing at the present time to interfere with an active lake trade right up to the close of navigation, which is expected to be about Dec. 1.

The following are the prevailing prices, per ton in the Ohio field:

Fancy domestic	$1.75@$2.25
Domestic lump	1.50@ 1.65
¾-in.	1.35
Nut	1.15
Mine-run	0.95@ 1.15
Pea and slack	0.40@ 0.50
Coarse slack	0.35@ 0.40

Cincinnati, Ohio

The tone of the local market is optimistic. Steam business is holding its own—if not slightly improved—and domestic trade is considerably better. Probably hundreds of furnaces in homes and steam plants in large buildings were equipped for gas consumption during the past summer and the retailers have begun to receive notice of it when they make inquiries as to why the usual order for the winter's supply of coal had not been received. The wholesalers feel it, indirectly, of course, but they are not so vitally affected because coal that cannot be sold in this immediate market is offered in some other market, while the retailer's market is very restricted.

Steam prices are unchanged, as also are the domestic. The car shortage on the Chesapeake & Ohio railroad continues and several operations report that they have had to shut down one or more days the past week in consequence. Cars are constantly being released from the lake trade, but the effect of that is of doubtful value as they are then used for long-distance hauls and are more difficult to keep track of than in the short haul to and from the lakes. Should bad weather add to the situation it is more than likely that the car shortage would assume a serious aspect.

The retail prices for fuel delivered are unchanged and continue as follows: Smokeless lump, $4@4.25; smokeless mine-run, $2.60@2.75; bituminous lump, $3@3.25; bituminous nut and slack, $1.90@2; anthracite, $7.25, since Sept. 1, when the price was advanced 25 cents.

Charleston, W. Va.

While there is an appearance of greater firmness and possibly a little more activity, there is no enthusiasm over conditions in the coal trade, especially as applied to the Kanawha and New River territories. It is opinion of some of the best judges of conditions and of the future that coal-trade conditions will not be very good until after 1912 has gone into history.

There are, however, a number of instances where mines are doing a big business and are running up to capacity, and what is more encouraging, are making preparations for greater outputs to meet the demands for their particular coal.

Indianapolis, Ind.

The brightest spot in the Indiana market appears to be in the Vigo field in the vicinity of West Terre Haute. John Nathway, sales agent for the Hall Zimmerman Mining Company, says that conditions are not nearly so bad as painted. "The summer has been unusually good with us and our mines have lost hardly a day throughout the season," said he.

On the other hand, operators in other fields say that during the past history of the coal-mining business in Indiana, October and November have been the biggest coal-selling months. Previous to this, during these months dealers have bought coal at the mines to fill their current demands against the winter needs. The operators say the dealers are taking less precaution to supply themselves this year in advance of cold weather. It is apparent, the operators say, that both retailers and consumers have decided to depend largely upon the open market.

Coal prices are demoralizing. With short demand for steam coal, operators have been trying to push domestic coal on the market and this has depressed prices still further. The domestic supply in market centers is said to be unusually low, considering the season, and a week or ten days of severe weather would exhaust the supply.

Minneapolis—St. Paul

There is a decidedly improved condition to be noted in the coal trade of the Twin cities. Retail orders have been coming in at a good rate, not in a rush, as is the case when a severe cold snap occurs, but rather a steady flow which the retailer has been able to keep up with. This is well, for the roads are in very poor condition for heavy hauling.

These two growing centers of population are evidently looked upon as natural outlets for dock coal, being but 150 miles from the head of the Lakes where an immense tonnage of both anthracite and bituminous coal is held in storage for distribution. It is estimated Minneapolis uses, in round numbers, 900,000 tons yearly, about 200,000 anthracite and 700,000 tons of bituminous. St. Paul uses about three-fourths of this amount to supply its fuel needs, and there is a healthy increase in tonnage yearly.

St. Louis, Mo.

Illinois Central mines are working about two days a week, and reliable reports state that approximately 400 cars per day, of Illinois Central equipment, are being pushed on side tracks in bad order. There is no improvement in strike conditions on that road, despite the statements of the company, and it is the general opinion that, unless the strike is settled in a few weeks, more than two-thirds of its coal equipment will be tied up.

There is some car shortage on the Iron Mountain and a lack of motive power on the Chicago & Eastern Illinois. Other roads are taking care of the business offered.

The prevailing prices per ton are as follows:

Franklin County:	
6-inch lump	\$1.65@\$1.75
3x6 egg	1.60@ 1.70
No. 1 nut	1.50@ 1.60
No. 2 nut	1.35@ 1.40
Carterville:	
6-inch lump	\$1.50@\$1.60
3x6 egg	1.45@ 1.55
No. 1 nut	1.20@ 1.30
No. 2 nut	1.00@ 1.10
Mine run	1.05
Screenings	0.55
Big Muddy domestic lump	\$2.10

All the above taking a 67c. freight rate to St. Louis.

Standard:	
6-inch lump	\$1.10@\$1.15
2-inch lump	0.95@ 1.00
Screenings	0.30@ 0.35

Gas-house and byproduct coke is moving freely, and smokeless is somewhat hard to get.

Colorado

The first snow storm of the year has just been experienced in this vicinity and while the snow was not general, a decided drop in temperature is reported from all districts, creating an increased demand for domestic coal for prompt shipment. Mines are not being forced to full capacity, but are enjoying a better business than has been evidenced for some time. Winter prices are now in effect at 25c. per ton more on all grades than the ruling prices of a year ago.

Effective Oct. 23, Northern Colorado lignite advanced 25c. per ton on the Denver market, and the better grades are now selling at \$2.80 per ton f.o.b. mine. The retailers have increased their prices correspondingly and are asking \$5.25 per ton, which is 75c. per ton higher than prices in effect a year ago, and 25c. per ton more than has been asked for several years past. A large percentage of the domestic coal used in Denver is of this grade and the Denver market practically consumes the output of these mines. Labor trouble reflecting increased costs and uncertain supply, is responsible for the advance.

Salt Lake City, Utah

Idaho dealers are beginning to realize that one mild winter with plenty of coal for everybody does not assure them a continuance of that condition for the following year.

Telephone and telegraph are kept busy these days with messages from the towns in that State, begging for coal of some description. Many dealers have paid visits to Salt Lake to make their appeals personally. With Utah dealers still unsatisfied, the prospects for any great amount of coal being shipped to surrounding States from Utah mines is not very great.

A large Nevada consumer this week offered \$3, f.o.b. mine, for 1000 tons. Retail trade is not strong, but as good as retailers can look for under mine conditions. There are rumors of an advance in the mine price, but nothing has been announced as yet.

Portland, Ore.

The coal trade here is not unusually brisk at this time because of the fair weather. The Diamond Crest Coal Company, 325 Railway Exchange building, is placing on the local market a coal from its mines at Tenino, Wash., for \$6.50 per ton in order to get it introduced to the consumer. It is said that the coal is a high-grade lignite and the company operates three mines.

Following are the prices asked here, per ton, including cost of delivery to points within the city proper:

Japanese	\$7.50	
Washington lignite	\$7.00@ 7.50	
Australian	10.00@10.50	
Rock Springs, Wyo.	10.00@10.50	nut \$9.50
Diamond, Wyo.	10.00	
Carbon Hill, Wash., lump	10.50	
Carbon Hill, steam	7.50	
Newcastle, Wash.	7.00	
Beaver Hill, Ore.	9.00@ 9.25	
Blacksmith coal	17.00	

San Francisco

The arrivals for the week by water are very light, consisting of but two small shipments, one from British Columbia of 1506 tons, and the second from Washington of 1000 tons, making a total of 2506 tons.

There is ample coal in stock to supply all immediate demands. Retail dealers continue storing for their winter needs.

Prices for the week remain unchanged, and are as follows, per short ton:

Wellington—clean	\$8.00
Wellington—average	7.50
Australian—clean	8.00
Australian—average	7.50
Seattle—clean	6.50
Seattle—steam	5.00
Utah, Wyoming and New Mexico—clean (for domestic use only)	8.15
Pennsylvania anthracite	15.00
Welsh anthracite	13.50
Colorado and New Mexico anthracite	12.50
Cumberland—smithing	12.50

Scientific Mine Management

Scientific Management—the cutting down of unnecessary expense and the obtaining of highest efficiency in order to secure maximum output at lowest cost—

Scientific Management is the thing today—in the Coal Mine as elsewhere.

The Boiler Plant is the Heart of the Coal Mine. High efficiency in the boiler plant is an essential part of Scientific Mine Management.

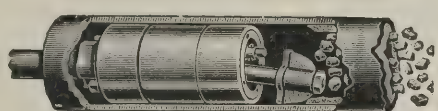
In no part of mine operation is the efficiency factor of Scientific Management so necessary as in the power plant, where the energy is produced for the running of the mine.

And in no part of the mine is efficiency so hard to procure as in the boiler plant, because of the unsatisfactory feed water conditions encountered near coal mines which, unless strong precautions are taken, cause scale to form on the boiler tubes, lessening the efficiency of the plant and so reducing the output of the mine.

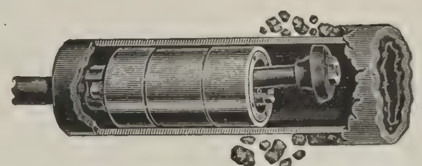
Scientific Management of the Coal Mine demands that the boilers be kept free from scale—not in any haphazard way, but in a *sure*, conclusive way.

The easiest, the quickest, the most economical and above all the *surest* method of keeping the boiler tubes free from scale is

The Dean Boiler Tube Cleaner



The Dean removing scale from the tube of a water tube boiler.



The Dean removing scale from the tube of a return tubular boiler.

We cannot emphasize too strongly the fact that the operator who runs a Dean through his boiler tubes *knows*, not *thinks*, that all scale has been removed. This is the difference between the Dean and other methods.

We can tell of one case where an Engineer of a plant purified his feed water, cleaned out his boilers frequently, and was even complimented on the condition of his boiler by the Inspector.

Yet we put a Dean in on trial and before his very eyes took out from two boilers 400 pounds of scale which had been reducing the efficiency of his plant and the presence of which he had never suspected.

The Dean operates on the principle of "broken-up vibration," caused by the striking of 3000 to 6500 light blows a minute. It goes where no inspector can and finds the hidden scale. It makes no mistakes. It cleans 10 to 30 tubes an hour, leaves every tube through which it travels as clean as a gun barrel.

Trial Offer And Guarantee

We sell the Dean Boiler Tube Cleaner entirely upon its merits.

We send it for trial on one boiler to let the purchaser see how it operates and prove to his own satisfaction that it does remove all the scale.

We sell it under a guarantee that it will pay for itself within six months or we will refund money.

The Mine Operator, Superintendent, or Manager who realizes the benefit of high efficiency in the plant of the coal mine will send for a Dean on trial.

COAL AGE

Vol. 1 NEW YORK, NOVEMBER 11, 1911 No. 5

I remember a man who bossed a small mine; the hardest kind of mine to run, if you ask me. But it was a brand-new proposition and we are looking for such to try our skill on. Everywhere you wander, the cry is, "Wish I didn't have to grow fruit on old dead limbs."

So this foreman was favored, and thought a royal flush was in his hand. He pulled 150 tons per day in small cars out of that mine with one mule. Both he and the "super" wore an ever-happy smile and believed they were being vindicated.

Moreover, it didn't faze the mule—this boss wouldn't misuse any dumb animal, and the driver was as kind as a trained nurse, getting good service with a cheery "Git up." The animal seemed to feel it was a pleasure to pull for him, and clipped a few seconds off his "reaction time" which, in a mule, is long for the brain and surprisingly short in the heels.

The mine was a simple problem: coal averaging 400 ft. from daylight, and a gravity proposition to the tipple. That foreman got a cost of coal he could never attain again. He had made a record and was now in the 2:10 class where prizes are high, but victories come hard.

Oh! he was not without troubles. There was a dip lower than the level of his ditch, and a lot of water too, but he put in a pump run by steam from outside because it was cheaper than to build a new drain. You see, it was a temporary plan, but he figured that perhaps a deeper dip lay to the left.

Then the haul was getting harder, but it didn't seem well to blast rock for so small a tonnage. And there were a lot of leaking doors and brattices, but 95 per cent. of all the current was traveling right up to the faces, and most anyone can pick a hundred mines operated under 1911 standards by technical grads, circulating only 75 to 80 per cent. of the air.

And he could have put in overcasts, but the mine wasn't big enough—yet. Outside there wasn't much track-room, not for a good mine, but he could provide that when he would. The drift leaked and the approach slopes were three to one instead of one to three, but it was summer and the banks didn't break with frost.

There was logic in it all, and, with delight, this foreman whittled that club, "cost of coal."

The tale is all told except to the dullard. That cost of coal didn't always remain so low, and the smiles left the foreman's face.

The dip got deeper, and then he couldn't get an appropriation to ditch it, although, of course, it was ditched later. Also, the grades had to be improved when the bulk of the coal came that way. He learned that his leaky stoppings were now putting only 50 per cent. of the air to the face, and a scant 25 tons was the output for a mule per day, since they had to "double" on the hills.

The mules' shoulders and flanks didn't any longer suggest trained nurses, and each animal divided its time between pulling the cars and trying to kick the lamp off the driver's cap. It was also discovered that the slowest mule, or the one that balked on the hard grade, set the pace for the "pit."

Many things went awry, and evils were left uncorrected, but how could it be otherwise? This foreman had his cost figure in mind; if I recall correctly, it was 0.754732, and that's a hard one to beat unless you want to go upward.

So no grading was done, and passing places weren't provided; stoppings were made of single boards and indifferently clayed; rails and timbers were left lying at random and all energy was concentrated solely on getting out tonnage.

Ab uno, disce omnia, from one learn about all. I tell of a little mine, for if I should relate about a large one, the story would but fill a bigger page. The first man on a job is tried, not by the right standards, but by his own. He runs ever to beat his own record. When he fails in that, there's likely to be a change in the personnel of the staff at that mine.

The record for a day is enticing, but it's the final result that counts.

The Fairmont, W. Va., Coal Region

By R. Dawson Hall

This region is on the southeastern edge of a coalfield stretching beyond the confines of the State. The mines show careful planning of the inside work for economy and safety. The alternating-current transmission is in accord with the most recent developments of electrical science.

The town of Fairmont lies on the Monongahela river, one and one-half miles below the junction of Tygarts valley and what is known as the West Fork. The two great anticlines of the Appalachian system lie to the southeast, and none but the more inconsiderable rolls lie to the northwest. The measures gradually dip as they are followed from Taylor county, so that northwest of the Monongahela river and its West Fork, the Pittsburg coal is unbroken, passing without trace of erosion beyond the confines of the State.

The Pittsburg coal is so even in quality and continues so unerringly wherever the surface has sufficed to cover it that where it occurs it is rarely possible to make out separate geologic areas unless we are willing to discuss very large bodies of coal. So the Fairmont coalfield must be regarded as merely a trade or economic designation arbitrarily applied to an ill-determined section of the unbroken field lying northwest of the line of the West Fork of the Monongahela river between Morgantown and Clarksburg and to that other and much broken field lying to the southeast of the same dividing line. Like all fields it is named after the natural line of approach rather than on any more scientific basis.

The Bed Mined Is the Pittsburg

The coal bed mined is the Pittsburg, but in one place coal is being taken from the Sewickley. Within the limits described, no attempt is being made to mine the Redstone. The Pittsburg coal is a good clean bed, the analyses of 51 samples taken by the W. Va. Geological Survey from as many different mines averaging as follows:

ANALYSIS PITTSBURG COAL

Moisture	0.7
Volatile matter	38.5
Fixed carbon	54.5
Ash	6.3
Total	100.0
Sulphur	2.25

The amount of volatile matter increases to the south of the field and the fixed-carbon content decreases. The sulphur percentage toward Fairmont is only about 1.2, and for the whole area north of Clarksburg it is only 1.7, but south of Clarksburg the percentage will equal nearly 3.2. It might be well to quote here the figures prepared by the Fairmont Coal Company, which is now merged into the Consolidation. This concern, before and after merging, mined only the Pittsburg bed. At 51 mines the average percentage ran as follows:

ANALYSIS FAIRMONT COAL COMPANY'S COAL

Moisture	1.43
Volatile matter	37.47
Fixed carbon	53.83
Ash	7.27
Total	100.00
Sulphur	2.59
B.t.u.	14,014

The thickness of the coal is about 8 ft. 6 in. At a hight of 4 ft. 6 in. above the bottom is a band ¾ in. thick, surmounted by about 6 in. of coal and another ¾-in. band; then follow 30 in. of coal of good quality, overlain with 12 in. of less desirable coal which is not persistent in its thickness.

The Sewickley coal in places runs as thick as 5 ft., but so far it is not favorably regarded for operating purposes.

Fig. 1. Consolidation Coal Company, Mines 43 and 63, Monongah, W. Va.

Coal Is near Water Level

The coal goes beneath the West Fork just above Watson, and emerges just above Monongah. Immediately below Worthington it again sinks below water level, emerging above Hutchinson near the line between Marion and Harrison counties. South of this point the Pittsburg bed is everywhere above water level, and this is also true below Watson except for a short length of immersion between Fairmont and Montana.

Thus it happens that nearly all the mines have slopes by which the cars are lifted to the tipple hight. The valley being narrow, in many cases, mines are opened on one side of the river and the coal dump and plants are situated on the other, with bridges connecting the opposing river banks.

Methods of Extracting Coal

The Consolidation Coal Company so completely dominates this region that a description of the methods and developments of that company is virtually a description of the district.

The mines have usually seven or eight headings in parallel for the main haulage roads and their airways. In the accompanying drawing, which shows a typical development, there are a manway and three main-haulage headings in the center, with two pairs of airways on each side of these four, one pair serving to feed the air to the south-face headings, and the other performing the same office for the north-face headings. These airways do not meet until they reach the shaft. The air is fed in every case by blower fans, so that the haulways carry return air. It may be said that the Consolidation Coal Company regards what little coal gas is in their mines as of small importance compared with the coal dust of which they have had such distressing experience at Nos. 43 and 63. However, the recent explosions of No. 49, arising from the entry of gas escaping from nearby wells, has somewhat modified the situation, the outflow from these being larger and less regular than that of the gas from the coal. Before this the company had been successful in keeping the percentage of gas in the returns down to a certain safe figure, far below possible danger. Every precaution is being made to remove the natural-gas menace and I do not know a place where the methods adopted to protect the mines against leakage from wells, have been more carefully considered. And if the present plans are consistently followed, it is unlikely that there will be any further explosions from that cause. The favor shown the blowing fan largely arises from the fact that the air can be saturated with water vapor before it is passed through the headings when the air is blown into the untraveled airways. It is impossible to humidify effectually where men and mules are passing. At best the heading can be made wet, but the air is not so filled with moisture that it is prevented from drying out the dust in the rooms.

The face headings are as a whole driven in pairs, the air traveling in by the airway and out by the haulway. These face headings are set at 1500- to 1800-ft. centers. The butt headings from them are 300 to 350 ft. apart. These butt headings are also in duplicate. But they are worked in groups of three both for purposes of ventilation and coal extraction. One current ventilates three pairs of headings passing up the airway and down the haulway of each in turn, but not returning to the main butt heading, being passed from airway to airway by rooms, driven specially for that purpose, just short of the face heading.

By this means, doors are kept off the important roads and if left open do not destroy the ventilation of the whole panel, but only of the three butt headings which form one unit.

Fig. 2. Consolidation Coal Company, Mine 26, New England, W. Va.

Narrow Chain Pillars

It is interesting to notice the narrow chain pillars 15 ft. wide, the headings being 25 ft. from center to center. This is good practice. It is safe to say that if the wing pillars are not competent to uphold the weight, no chain pillars can make up for their weakness. There is no lack of strength in the wing pillars. Note the pillar 175 ft. wide flanking the main butts. The block of coal guarding the face heading from the weight of

the secondary butts is never less than 100 ft. thick. The curves to these butt headings are quite sharp, being struck off at a radius of 63 ft.

The last rooms in the butt headings are driven first and run completely through to the back heading. As soon as they reach their destination they are drawn, the withdrawing line being at about 45 deg. to the line of the face. Thus there are but few men in any heading and the combining of the three headings in a common split is in accordance with good practice. In other regions the angle with the face is much less and consequently a large number of men work in each heading, which plan influences the splitting provision.

Recovery Nearing 95 Per Cent.

It will be seen that with rooms only 20 ft. wide and placed at 60-ft. centers,

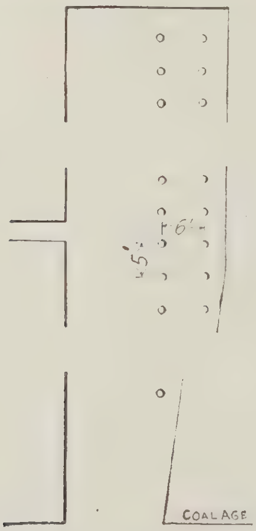

Fig. 3. Room Posting

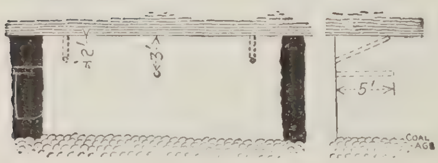

Fig. 4. Placing Shots

the recovery of first mining is nearly 33 per cent. As the cover is about 250 ft., it will be realized that a conservative method of work is being followed. In many cases the proportion of coal finally extracted in the new development is 93 per cent. of the whole coal even where the roof is weak. In much of the old work in the region, rooms have been driven up and allowed to stand with the pillars intact, but these are now being drawn. It is a clearly demonstrable fact that conservation pays, not merely because it saves coal, but because it enables the most to be gotten out of improvements and developments and staves off by some few years the unwelcome day when haulage, drainage, ventilation, power transmission and equipment of all kinds become burdensome in the extreme as the workings are pushed further and further from the original point of development. Many mines come to an untimely end because lack of conservation has made costs of production so high that they can no longer be worked at a profit.

Underground Workings Have Paramount Consideration

To promote this conservation, the Consolidation Coal Company has made a study of the best methods of mining, and has not left the manner of working to the individual discretion, or rather, as it is too often, to the individual indiscretion of the miner. Thus room driving, post setting, pillar drawing and placing of shots is regulated, and from this close surveillance comes the high percentage of coal saved. In many recent mines, there has been a notable and deplorable tendency to give a scientific treatment to outofdoor problems and to leave the subsurface operations to the mine foreman as soon as the shaft bottom has been laid out. Yet the underground problems are the most important of all those pressing for consideration, and should receive first place.

In Fig. 3 is shown the ordained method of placing props in a standard room which measures from 18 ft. to 20 ft. wide.

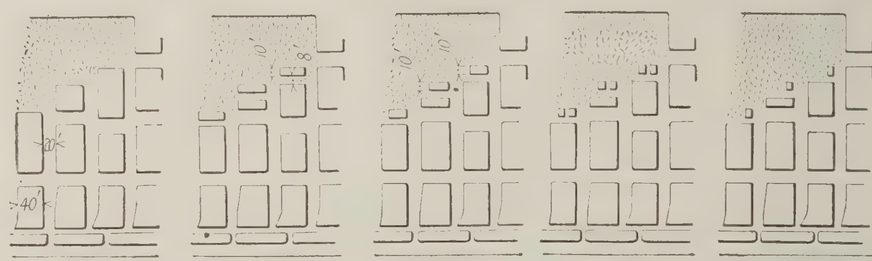

Fig. 5. Fig. 6. Fig. 7. Fig. 8. Fig. 9.

Method of Extracting Pillars, Fairmont, W. Va.

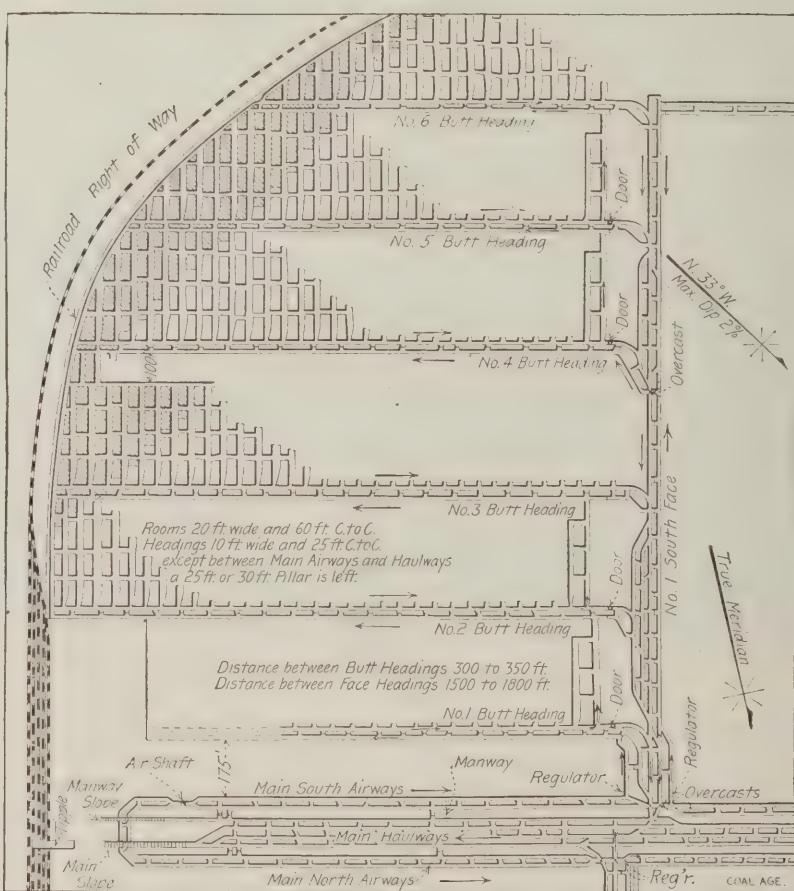

Fig. 10. Method of Mining in Fairmont Field—Retreating in Blocks of Three Headings

These props cost about 12c. apiece and are used with economy. About 63 per cent. were recovered in Mine No. 25. The miner is paid 5c. for every prop he saves. In Fig. 4 is shown the method of placing boreholes after undercutting.

The so called "gut-shot" is placed first, level and centrally located, and the two rib shots are placed next in boreholes bearing up toward the roof which they reach at their further extremities. The rooms are all widened in the direction of advance of the pillar drawing. There is no departure from this rule, which is essential for complete extraction.

Method of Pillar Drawing

Fig. 5 shows a condition in pillar drawing which is, of course, never reached in practice. Three room pillars are drawn fully across from room to room simultaneously. This synchronism is used here to simplify description, and the same objection may be made to all the following figures, and the same reason must be held to extenuate the variation from actual practice. Fig. 6 shows the appearance after a crosscut 8 ft. wide and the full width of pillar (40 ft.) long has been driven so as to leave a 10-ft. strip fronting on the caved area. This strip is reduced by extracting 8 or 10 ft. of the far end or as much of it as is possible. This is shown in Fig. 7. In Fig. 8 this block is shown split by a narrow crosscut leaving two pillars almost

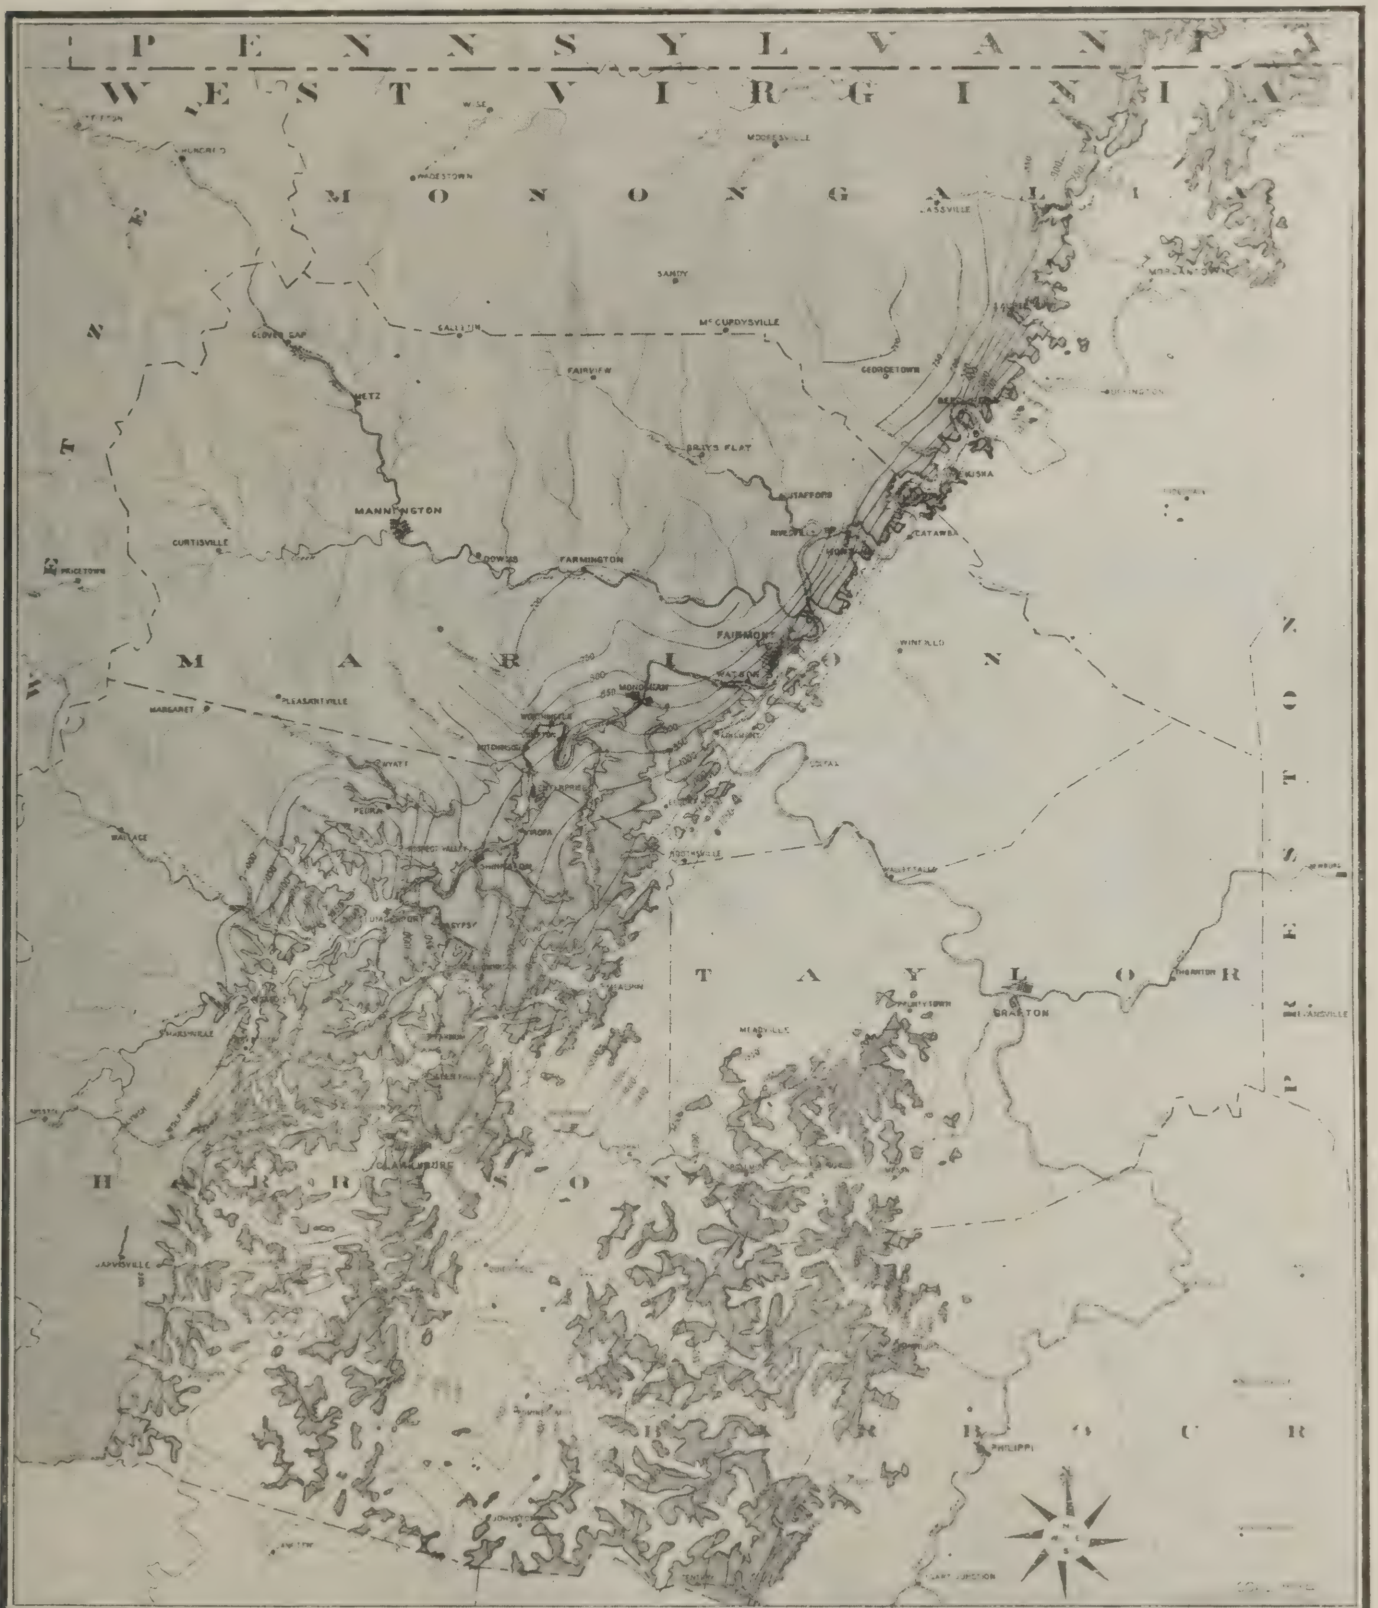

Fig. 11. Pittsburg Bed with Contours, Fairmont Region, W. Va.

square. In Fig. 9 the remoter pillar has been withdrawn, and all that remains to be done is the removal of the nearby pillar. After all, this is the most difficult work and it is here that what little coal is lost, has to be left in.

Fans Fixed and Portable

The fans used are powerful and housed in housings with roofs so weak that they are expected to be lifted off the building should an explosion occur. However, these mine safety valves are loaded more heavily here than in most regions, and it is questionable whether a happier mean could not be struck between the overlight explosion door of the fan makers and the roof which here finds favor as a release valve. It is not easily replaced. Its resistance is not easily measurable. The average explosion door is excessively sensitive, and perhaps the method here preferred may be ample to safeguard the fan. It may be said here that the Consolidation Coal Company has a portable fan loaded on a truck ready to be hauled to any of its mines should one of its fans become disabled. There is no lack of intelligent foresight being used to prepare for the possibilities of a disaster. Humidification and permissive explosives have been adopted for the prevention of explosions, but the belated cures have not been overlooked, for the owners and managers know that the best laid plans are liable to fail under stress of certain combinations of circumstances.

Separate and Connected Mines

As merely a sample evidence of that caution may be mentioned the barrier pillar between Mines 43 and 63. This is in one place only 12 ft. thick. An undercut 6 ft. deep, tapering down to nothing at the rear, is cut from No. 4 south-face heading of No. 63 mine and another like cut is made from No. 3 south-face heading of No. 43 mine. The two mines are disconnected by this barrier so that the misfortunes which may happen to one mine will not involve both, but at the same time in a short while rescuers could pass from the one uninjured mine to the very forefront workings of the other.

There seems to be all through an earnest attempt to determine a course of action before a disaster occurs, and only when this is done will rescue work be really effective. In passing, it may be said that the Consolidation Coal Company's officials firmly favor reversal of the fan in cases of explosion and recently had brilliant confirmation of their reasoning in the successful recovery of No. 49 mine after a severe natural-gas explosion.

The coal gas in the mines is easy to control as it occurs not in the falls, but in the virgin mineral and does not escape in blowers. There are no safety lamps used. Horses and mules are used for gathering, but motors are used for the main hauling, bringing their loads to the foot of the slope. From thence they are drawn out by rope.

Passing Railroad Cars under Tipples

The older mines of the region have wooden tipples, long and high like those of all regions where coal has to be sized. There is no need for cleaning other than such as is performed by the car trimmers. Perhaps the most noteworthy feature is that most of the tipples have conveniences for the lowering of railroad cars without recourse to the inefficient pinching bar which is always dull and uncertain in action. Here either the car is pulled forward by a rope or else the grade is enough that the car constantly needs restraint. In the latter case no reliance is placed on the car brake, but a clever patented clutch device with a long lever handle is used on a third rail. This is worked from the ground. One man can handle three or more cars. He passes for this purpose from track to track and employs his entire time on this service. The device which is moved with the car is attached by a chain to the drawbar of the gondola; thus the feed can be made absolutely certain. The device is to be commended as it saves labor, time, life risk and expensive wrecks.

The Purposed Electrical Development

The Consolidation Coal Company is endeavoring to bring its electric work into line with recent developments and it is now taking current at 22,000 volts from the lines of the Fairmont & Clarksburg Traction Company. It is using 2200 volts for its main pumps and 250 volts for mining machines, haulage motors and the smaller pumping equipment.

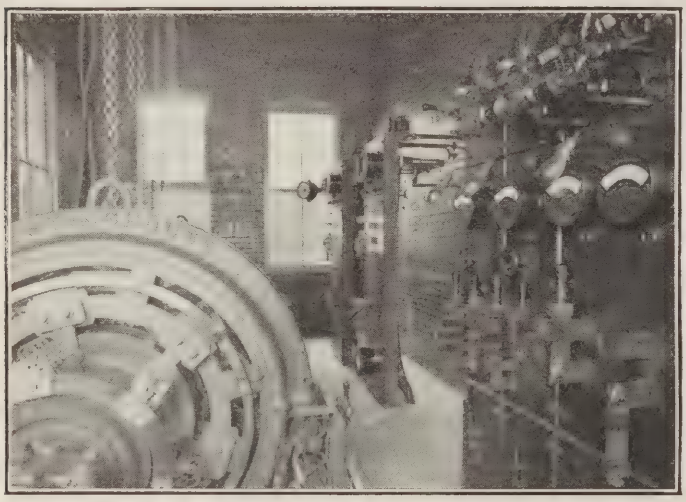

Fig. 12. Rotary Room at Mine No. 63

Fig. 13. Transformer Room, Monongah, W. Va.

The following description of the plant that it is about to install was given me by one of the officials of the company: Three gas engines of 1500 h.p. per unit will operate three-phase 2200-volt 60-cycle generators and the current will be stepped up in the power plant by means of single-phase transformers connected in delta. By this means the current will be raised to 22,000 volts. All transmission lines will carry this current. In the substations it will be stepped down by transformers to 185 volts of alternating current, then by means of rotary converters it will be changed to 250 volts direct current. This covers the main system. The copper conductors carrying the full current of 22,000 volts will aggregate in length, 31 miles. Wherever it is considered economical for the reduction of the amount of copper necessary in the feed wires, substations will be placed within the mine. Where that is done the current will be transformed from 22,000 volts to 2200 at the surface.

The power will be taken into the mine through three-conductor armored cables placed in a bore hole located exactly over the substation. Where there are large pumps of 100 h.p. or over, they will be operated by 2300-volt induction motors. Wherever practical, the pump and substations will be placed close together for operation by one man. Telephones will be put in substations within the mine connected with the outside.

High-tension Substations

Wherever 22,000 volts are to be taken to a substation a separate high-tension room is used. This room will contain electrolytic lightning arresters, except where these are placed on the roof. This room will also protect the oil-circuit breakers and substation transformers. The low-tension room will contain rotary converters and a switchboard. In each rotary room a triplex chain block, mounted on a trolley, will be used for placing and handling heavy machinery. For use in switching on the 22,000-volt transmission line, three-pole single-throw and three-pole double-throw and fused horn-gap switches will be provided. These will be mounted directly on poles and will take the place of special switching towers which contain the usual oil or stick-type circuit breakers. It will be seen that this proposed plant is to be fully uptodate and its successful installation and operation are anticipated with interest. The illustrations show parts of the plant already completed and in operation. These receive power from the F. & C. Traction Company.

A cordial recognition should be given to Everett B. Moore, chief engineer of the Consolidation Coal Company, for assistance in obtaining the foregoing information. It would be hard to acknowledge duly the many courtesies extended by a host of others during my trip of inquiry.

Proposed National Coal Combine

By Walter Williams*

Mr. Williams shows the necessity of a national organization of the coal operators, such organization to be subject to the restrictions of a Government commission.

*President, Hart-Williams Coal Company, Chicago, Ill.

NOTE—Paper read before recent meeting of American Mining Congress, Chicago, Ill.

The conditions that have brought about our present status in the mining industry are merely discovered between the vested rights of property and the rights of men. We are only reaping the whirlwind that has been sown. The tremendous opportunities for industrial development in this country following the Civil war, caused the creation of great corporations, such as the Standard Oil Company and the great railroad systems of this country, and they have abused the privileges that were theirs, as men always do. They are not to be blamed, because the law permitted it and the people are to blame because they made the law or failed to make the law, and the condition that confronts us today we cry out against. The assault upon capital, the assault upon the railroads, the assault upon corporations is merely the natural result of the great combinations in this country.

The Sherman antitrust law was a blind effort on the part of the great masses of the people who felt the repression, who felt the effort of these gigantic corporations to get control of the sources of supply, the necessities of life, the transportation of the country, and feeling that the Sherman antitrust law was a blind effort on their part to check it, and naturally such blind effort was not constructive in its nature. As one of the speakers said, it was repressive, and the Sherman antitrust law was merely a blind strike in the dark on the part of the great mass of people to check this.

The Present Law

The Supreme Court of the United States in my judgment could not do anything else than what it has done. The purpose of the Supreme Court is not constructive, it is merely interpretative. This law is put on the statute books and it is theirs to interpret and the executive of this country to enforce; neither the Supreme Court nor the President are to blame. They can do nothing else under the circumstances than just what they have done. Mr. Taft and Mr. Wickersham are merely following out their plain duty, when they say that these gigantic corporations must be dissolved.

Now what must be done? They are doing their duty, but it is not going to relieve the situation in this country. It is not going to relieve the fearful condition that the coal business of this country presents. The constructive part must be done by the legislatures of this country, and now that the Sherman antitrust law has been interpreted, and now that the effort is being made to enforce it, the people are becoming aroused to the futility of the enforcement of that law and the tremendous loss that is going to come if it is enforced.

Combinations in this country are inevitable. All we need, or the thing we need, is not to do away with combinations. The thing we need is to do away with unreasonable oppression which combination gives an opportunity to put into effect, and combination must be permitted.

It is futile to expect a congress that is made up of a changing body of men, changed every two years, to investigate the industrial condition of this country and construct laws that are going to meet the needs of this country. What can a man from any district know about legislation, and what can he know about constructive statemanship? What if he does know can he accomplish in that time? We must resort to some form of commission, a scientific commission, a commission that will be appointed or constituted to exist over a term of years, who shall go into this question and study it to the botom, study it from the scientific standpoint and arrive at a just conclusion as to what is right between all the parties interested.

Restrictions Necessary

Now you men who are in the coal business are clamoring for an amendment to the antitrust law that will permit you to combine, and there you stop. You must be satisfied also to not only be permitted to combine, but to be restrained from plundering the great body of people by the use of strong combination or a too powerful one. I am a coal operator myself and I see the necessity for combination, but, gentlemen, we must take with it the inevitable consequence that will follow, the restrictions drawn around us so that we cannot in certain seasons of the year exact an exorbitant tribute.

Why have we not acted? A large measure of blame was put on us as well as the Government, and one reason why we have not acted we realize the condition is because we are born gamblers, and there is not a man in the coal business today, and bad as the condition is, but what hopes that the recurrence of that high tide of prosperity that occasionally comes to the industry will arrive before he is forced into bankruptcy, and out of business. We are satisfied in the summer time to trade a dollar for ninety cents, in the hope that when September and the winter months come we may trade the dollar for $1.75 or $2. Business will have to be put on a basis of reasonableness, which shall prove to be permanent.

Now with the desire for combination must come also the recognition that there must be restriction of an unlimited profit. That has come to the railroad. The com-

mission has fixed certain maximum prices that they can charge for the service they render. It would not be a bad thing for the coal industry and I offer it as a suggestion. Suppose we had a commission that would fix the maximum price that we could charge for our product, and that this price was fixed after an intelligent study of the business by all of the parties interested; the operator, the workman and the public; and fixed so that there would be a reasonable profit, because the hazards of the business demand that the profits shall be more than comes to the ordinary business. Then permit combinations whereby the maximum price that the commission fixes shall be the minimum price that the operators will charge to the public. The commission idea is the one that is going to make itself felt in every line of endeavor. I am a democrat in politics, but I am heartily in favor of Mr. Taft's idea, and this is in opposition to many of the ideas of the party that I represent. I can see a certain amount of justness in the attitude that he has assumed with regard to the revision of the tariff.

Concerning the Illinois Legislature

The legislature of Illinois, as at present constituted, is as wholly incompetent to deal with this question as a new-born babe. Its shame is written broadcast all over this country, and how can you expect a body of men such as that to deal with a question that is fundamental in its nature, and that affects the business interests and a tremendous capital and a tremendous body of men.

Over 50,000 men are working in the mines of the State of Illinois, millions of dollars are invested, the great population is dependent upon the industry in this country for its fuel, and tremendous industries are dependent upon it for the power to turn their wheels. Now to submit this question to a body of men elected haphazardly, this year in and the next year out, would be disastrous. It must be submitted to a body of men who can investigate it and who will do it and bring in a report, bring in constructive legislation that will have in mind the rights of capital to a reasonable profit upon their investment and upon mental toil; and, on the other hand, of labor to a reasonable share of the profits in the industry in which the men toil, not only for their daily bread, but an opportunity to lift their eyes above the ground occasionally and see a glimpse of an opportunity for education, and some of the cultural things of life.

We cannot continue as we are. We must be allowed to combine. If we are not allowed to combine the ruinous competition in which we are engaged will wipe the industry out of existence, so far as those engaged in it are concerned. The industry will not be wiped out, but new capital will come in and reorganize it upon a new basis. Let me say to you that those who today have opposed the enactment of any law permitting greater profit to the business, who would oppose any change in the Sherman antitrust law, would be short-sighted.

Let me tell you they will pay high interest for every dollar's worth of coal that they are buying for 90c. For every dollar's worth that they buy for 95c. they will pay $2, and why? Simply because the profits that have been lost must be made up. The bankers must be repaid the money that has been borrowed, the red ink must be written off the ledger, and the tremendous waste in the industry as it is today constituted must be paid for in the future; and we have no right and those who are buying coal today have no right to plunder the resources of this country, to waste the heritage of those who shall follow, in a crazy desire to buy a thing for less than it is worth, a thing which is one of the greatest necessities of human life.

Anthracite Miners' Demands

Special Correspondence

The convention of the anthracite miners' union, districts Nos. 1, 7 and 9, was brought to a close at Pottsville on Nov. 3, after formulating ten demands which are as follows:

1. We demand that the next contract be for a period of one year, commencing April 1, 1912, and ending, March 31, 1913.
2. We demand a work day of not more than eight hours for all inside and outside day labor, with no reduction in wages.
3. We demand recognition of the United Mine Workers of Districts Nos. 1, 7, and 9 as a party to negotiate a wage contract and the right to provide a method for the collection of revenue for the organization.
4. We demand a more convenient and uniform system of adjusting local grievances within a reasonable time limit.
5. We demand an advance of 20 per cent. on the rate of wages for all employees over and above the rates awarded in 1903.
6. We demand a minimum rate of $3.50 per day for miners and $2.75 for laborers.
7. We demand that the system whereby a contract miner has more than one working place, or employs more than two laborers, shall be abolished.
8. We demand that the rights of the check weighman and the check docking boss shall be recognized, and that they shall not be interfered with in the proper discharge of their duties.
9. We demand that all coal shall be mined and paid for by the ton of 2240 pounds, wherever practicable.
10. Your committee would recommend that a joint-scale committee, composed of the executive board of the three anthracite districts, together with the national president, be appointed by this convention and clothed with discretionary power to negotiate an agreement on the basis agreed to by the convention, and in the event of their being unable to do so, they shall be empowered to order a suspension of work in accordance with the laws of the organization.

The demands are much more radical than any of the delegates to the convention anticipated. They were formulated by the executive board of the three districts and were practically accepted without discussion or mitigation by the convention. After the convention had adjourned, the delegates seemed to be very reluctant to discuss them. All who were approached on the subject said that they approved of them heartily; that while they might be modified in this direction or that as a result of the negotiations with the operators, yet that on the whole they were equitable and that they must be conceded in principle if a strike was to be avoided.

President White aroused the enthusiasm of the delegates when he declared emphatically that the Conciliation Board must be wiped out and that the executive boards of the district unions must be recognized by the operators as representative of the national organizations. On the whole, however, he was optimistic as to the outlook for a peaceful settlement of the demands which had just been officially issued and seemed confident that the task of arranging an agreement on the basis of these demands would be easier than in 1900 and 1903.

Consternation In Business Circles

On the other hand, the demands have caused consternation in business circles in the anthracite regions. Business men recognize that the operators are in no humor and in no position to grant even a moiety of the demands, and they anticipate a prolonged strike if the last agreement is not accepted as a basis of the next.

An official of one of the largest anthracite-coal companies said: "The demands of the convention are preposterous. These demands simply amount to a requisition that we hand over the control of our property to the miners' union and that we act in subordination to them as their selling agents. We are not going to do anything of the kind. We are prepared to take into consideration any reasonable demands that the representatives of the miners make for an increase of wages on the basis of the existing agreement but we cannot and will not go any farther."

The Bituminous Coal Trade

By A. J. Moorshead*

A review of the Illinois coal industry from its infancy. Some startling comparisons are shown regarding cost of production and selling price. The evils of overproduction are discussed and remedies suggested.

*President, Madison Coal Corporation, St. Louis, Mo.

Note—Abstract of paper read before the American Mining Congress, Chicago, Ill., Oct. 25, 1911.

So varied are the underground conditions and methods employed in coal mining in the State of Illinois alone, both with reference to the seams worked (from 30 in. to 10 ft. in thickness); the wide range of prices per ton paid to the miners; difference in quality of product; the variable cost of putting the coal into the cars for the market, that it makes a somewhat intricate and difficult subject to handle, particularly when coupled as it is with the attempt in our dealings with the Mine Workers' organization to make each district fairly competitive with all others in the marketing of the product; therefore, the subject covering the entire country can only be reviewed in a general way.

With the exception of two or three States and some particular districts in some States, the industry was in a reasonably prosperous condition prior to the fall of 1907, when a general business depression occurred, and, with others, the coal industry suffered a material curtailment in production and a general lowering of values at that time. During the following year the production declined some 64,500,000 tons, but this loss in production has been subsequently overcome, and the figures for 1910 record the largest tonnage in the history of the industry.

With the further decline in prices during the current year, the situation has become a serious one, and in certain competitive districts where competition is unusually keen and where low prices have steadily prevailed for the past four years, many of the operators are dangerously near complete bankruptcy, and some means must be devised to relieve this situation if it is possible of accomplishment; otherwise the failure will be seriously felt by manufacturers and retail dealers everywhere.

Data Collected

In order to obtain the most authentic information possible along these lines, the secretary of this Congress sent out blanks to all the principal coal operators scattered throughout the country, making inquiry along the following lines:

1. Capital invested in business.
2. Average total cost of production.
3. Average labor cost per ton (mine workmen only).
4. Average cost of administration.
5. Average selling price at mine.
6. Estimate of increased cost necessary to meet demand for conservation.
7. Average depreciation of values per 100 tons daily capacity.
8. At what price coal must sell.
9. What percentage of coal is sold at a loss.

Briefly stated, these statements revealed the following conditions:

That for every ton produced annually, there is an average investment of $1.41 in coal lands, machinery and equipment necessary to that production. These statements show that increases in cost of production have been general in all States, varying from a fraction of a cent in States like Tenessee and Kentucky, to 28c. per ton in the southwest. The average increase is near 7c. per ton in all fields.

Increased selling prices are generally reported for 1910 averaging 4c. per ton, but it is not sufficient to offset an increase of 7c. per ton in production costs, during the same period, so the year as a whole shows a decline in profit.

During 1910 the total cost of production is estimated at $1.07 per ton. The cost of mine labor and mine supplies total 95c. per ton, and the cost of administration, such as office expense, sales expense, accounting, insurance and taxes, legal expense, etc., usually classed as general expense, was 12c. per ton. This does not include interest, depreciation or profit.

The average price obtained at the mine was approximately $1.11 per ton. The increased cost necessary to meet the demand for conservation was estimated in different fields from 2c. to 15c. per ton, with a possible average of 5c. in the country as a whole. The depreciation of coal reserves and plant equipment would require a fund of approximately 4c. per ton.

The increased prices necessary to make the business show a fair return on the money invested ranged from 5c. to 25c. per ton in various regions. The average increase requested would approximate 12c. per ton.

Over Production

Statistics show that while our bituminous coal production increased rapidly from nothing in 1821 to 1,111,156 tons in 1842; to 10,625,381 in 1865; to 105,268,-963 in 1891; to 306,138,096 in 1906; and to 415,500,000 tons in 1910; our consumption kept ahead of or apace with production until 1891. In 1821, consumption was 19,617 tons in excess of production; in 1842, it was 123,879 tons in excess of production; but in 1891, the total consumption was only 105,016,407, or 252,556 less than production, and the difference has steadily increased until in 1906 consumption was 6,002,051 less than production. The excess of production over consumption has steadily increased each year, and has resulted with mines operating to a restricted capacity.

A further example of our over-production and still greater over-capacity was demonstrated during the strike period of 1910 in Illinois, Indiana and the southwest:

Illinois was idle six months of the year, but produced 45,900,246 tons as compared with 50,904,990 the previous year, working twelve months.

Indiana was idle some thirty days and produced 18,289,815, as compared with 14,834,259 in 1909.

Oklahoma, Arkansas, Kansas and Missouri were also idle six months in 1910, due to the strike, and the production showed an average decrease of only 20 per cent. under the figures for 1909.

The possible capacities of West Virginia mines is fully 75 per cent. over the present total production. The Pittsburg and No. 8 Ohio districts are reduced to 30 per cent. operation during 3 or 4 months of each year, while navigation is closed on the lakes. There are very few properties that have operated over 225 working days per annum during the past three years.

Tonnage Increase

This over production and over capacity to produce has resulted in a ruinous competition to obtain business. Many of our coal properties have fixed charges in the nature of bonds and other obligations, such as minimum royalties, and in many cases the management figure their losses less by taking the low prices and operating full time than by obtaining their proportion of profitable domestic business.

The develpoment of so many new high-tonnage plants in recent years has also had a marked effect upon the industry. When it is realized that our production and consumption to date have practically doubled every ten years, the large increase in the number of new mines can be appreciated. The "deadwork" haulage, drainage and ventilation costs are always lower in new development, on account of the concentrated area under operation, and they are able to produce coal much

cheaper than their older competitors. They fix the prices in the markets, which must be met by the older mines, but in time they have the same situation to face.

To meet this competition, underground development is too often carried on in such parts of the mines as can be made to produce cheaply and in order to escape the heavy yardage prices, excessively wide entries are driven, and this condition coupled with the narrowing of pillars in order to lessen the cost of operation, ultimately causes heavy falls and squeezing to such an extent that the mines are robbed of half of what would otherwise be their natural existence, and in their early abandonment large acreages of coal are wasted without hope of recovery.

Price Fluctuations

Statistics show that the average prices received at the mines during the past seven years are as follows:

1904	1905	1906	1907	1908	1909	1910
1.10	1.06	1.11	1.14	1.12	1.07	1.11 est.

The average price for the entire period has been $1.10 and the fluctuation between the maximum and minimum prices has been only 8c. per ton. It is also interesting to note that the prices for 1910 and 1904 and the average price for the period are practically identical.

During 1910 the increased cost of production as compared with the previous year is estimated at 7c. per ton in all fields. Some idea of the increased cost of producing coal can be obtained from the following table, which shows the mining rates in the four largest States operating with organized labor. All other districts show similar increase, but the amount is difficult to ascertain:

	Base Rate Illinois	Indiana Mine Run	Bitum. Lump	Thin Vein W. Va.	Hocking Ohio Lump
April 1, 1898, to April 1, 1900......	40c.	40c.	66c.	66c.	66c.
April 1, 1900, to April 1, 1903......	49	49	80	80	80
April 1, 1903, to April 1, 1904......	55	55	90	90	90
April 1, 1904, to April 1, 1906......	52	52	85	85	85
April 1, 1906, to April 1, 1910......	55	55	90	90	90
April 1, 1910, to April 1, 1912......	58	58	95	95	95
Increase, 14 years......	18	18	29	29	29
Equivalent on run of mine basis......	18	18	18.74	18.74	18.74

The above increase applies only to the "mining rate"—that is, the amount paid to the miner for loading one ton of coal at the face, and proportionately higher wages are paid to all other mine workers. The full increase in cost of labor per ton over this period is, therefore, 27c. per ton, and approximately 9c. of this increase has been taken since 1904.

With prices practically stationary during this same period the profit to the operator shows a net decrease of 9c. per ton.

We have already stated that for every ton produced annually, there is an average investment of $1.41 in coal lands, machinery and equipment necessary to that production.

The National Trade

Based on an annual production of 415,000,000 tons of bituminous coal, there is an investment in the business of some $585,000,000. An investment in an industry of this nature, carrying the risks to life and property which mining industry does, and the hazard of faulty conditions of seam, which no man can definitely foresee, should net at least 10 per cent. in return as interest on the capital invested, after setting aside a sufficient amount—estimated at 4c. per ton— to cover depreciation of equipment and exhausted coal lands.

The mining industry should net to the owner annual earnings of $75,100,000. They earned $16,600,000 in 1910, and the current year will show still further reductions. In other words our coal operators are absorbing as losses in excess of $58,500,000 per annum, or slightly in excess of 14c. per ton.

Over-production is the cause of this extremely deplorable situation. It has created a destroying competition in which only the strongest can survive. It has caused a general unrest in the industry and dissatisfication to mine owners and mine workers alike, and the question before us is how this over-production may be taken care of and the business placed on a remunerative basis. Two solutions are suggested.

Suggested Remedies

First. The creation of district sales agencies to handle the entire produce. These agencies would control the total output and name prices which would return a fair profit on the investment and at the same time permit the necessary expenditure for conservation of resources and careful and safe mining. Such agencies would result in a very large reduction of the present sales cost, and, by concentrating the mining operations, the ultimate cost to the consumer would probably show little increase. These agencies could maintain a more uniform distribution and by concentrated effort could probably reach new markets which are not being supplied from the United States.

This plan would require the alteration of the Sherman Anti-Trust Law and the creation of an Interstate Coal Commission. The commission would have to pass upon the justness of prices established by the various district agencies, to see that owners obtained fair prices only, and to hear the public voice in reference to such matters. The commission should also control the opening of new mines in such a way as to keep production and consumption apace with one another.

Second. The Government could assist in the development of foreign export trade. A large percentage of the total production of this country is available for profitable export, and by directing the surplus production from Eastern Pennsylvania and Eastern Virginia, which is now encroaching upon the trade formerly enjoyed by Illinois, Indiana and Ohio, the solution would at least be partly reached.

Foreign Remedies Used

Other countries have had their coal problems similar in all respects to our own, as now existing.

Great Britain met it by the most careful of mining methods and preparation of the product; and combination with transportation interests have gained for her the markets of the world for her surplus, at highly remunerative prices, and this result is only possible by continuous operations and large export shipments. British exports have been:

In 1907....................	63,600,947 tons
In 1908....................	62,547,175 tons
In 1909....................	63,076,799 tons
In 1910....................	67,085,476 tons

It took Germany many years to perfect a coal syndicate which, under a single sales agency, with the coöperation of the government, has produced substantial returns to the mining companies, and at the same time increased the export tonnage; and there was shipped in this particular class of trade:

In 1909....................	10,321,536 tons
In 1910....................	10,963,195 tons
In 1911....................	12,614,952 tons

It should be the duty of this congress to carefully consider ways and means of working out the problem; additional legislation is necessary and capital, together with labor and the consumer, should appreciate the benefits to be derived from placing an industry of great magnitude upon a substantial basis.

Wonderful results have been accomplished for the benefit of agriculture by the national government appropriating from $20,000,000 to $40,000,000 per year for the last twenty years for that particular industry, yet mining—important and hazardous as it is—has received but little consideration. This organization can, by thorough, concerted and determined action, not only arouse public interest in our cause, but the State and national legislators will, beyond doubt, when the condition of the industry is properly made known to them, afford relief no less generously than Great Britain and other foreign governments have done.

Compensation vs. Liability Acts

In presenting the result of the labors of the special committee appointed to consider and report upon the subject of a workmen's compensation act, I desire to call to your attention some of the things which form the basis of the reasoning of your committee.

The subject of employers' liability and workmen's compensation, in one form or another, has agitated the minds of men for years. The justice of it all is generally conceded, and American industry is still seeking the best direction in which to move to accomplish the object of its faith.

The coal-mining industry is no stranger to either "liability" or "compensation," nor did it wait for law to suggest, demand or compel a reasonable care, in one form or another, of those injured in the pursuit of the industry.

It is natural, then, that a subject of so vital importance to the industry should engage the serious attention of the Mining Congress.

One of the most important points in the whole matter is to decide upon the best direction to follow. On this point we have the experience and opinion of practical men in this and other countries. It has been stated that what has been done in England, and what has been done in Germany, are the most important types of action on this subject which we can study.

An English Opinion

A. H. Gill, member of Parliament, of Balton, England, says in substance: "In England, before the eighties, the common law was the only means of adjustment between the injured and his employer; when negligence of the employer was not apparent or proved, it was hard to get compensation. The working people became dissatisfied and began to agitate for a new law, and as the result an Employers' Liability Act was passed in 1880, and while it was an improvement on the common law, the act was not a success, as it embodied the doctrine that an employer should not be liable unless negligence was proved. It has, always, been difficult to succeed in an action under the act, as so many means could be found of resisting a claim. The result of the failure to secure compensation caused a further agitation for an improved method of dealing with the problem. This agitation bore fruit; for in the year 1897, an act was passed known as the Workmen's Compensation Act. This act did away with the doctrine of contributory negligence and made the employer liable to pay compensation to a workman who lost

By John H. Jones*

After reviewing the experience of various countries, a workmen's compensation act is urged as preferable to employers' liability from the standpoint of the mining industry. The former may prove difficult to frame. The latter is believed to be wrong in principle and practice.

*President, Pittsburg-Buffalo Coal Company, Frick building, Pittsburg, Penn.

NOTE—Address read before meeting of American Mining Congress, Chicago, Ill.

time through any accident which occurred while following his employment."

It is not necessary to enlarge upon this act, but simply to draw to your attention and emphasize the fact that 26 years of agitation by workmen, and 26 years of study and experiment, by practical men, resulted in a *Workmen's Compensation Act.*

This opinion is fully confirmed by Attorney Packer, of Washington, D. C., who was retained by the United States Government to investigate the matter.

Two Views on Liability Act

Another opinion dated Washington, D. C., Dec. 24, 1910:

"The Illinois legislature should enact a liberal employers' liability act at the special session and *then undertake an investigation with a view to the introduction of an automatic compensation law, for THAT view observers now regard as the most feasible and just solution of the vocational ills, accidents and death.*"

(Signed) Samuel Gompers, president American Federation of Labor.

And another:

"In spite of the fact that every one of the industrial nations of Europe has discarded the system of paying damages on the ground of the liability of the employer and has adopted in its stead the payment of compensation for industrial accidents: *in spite* of the fact that New York has adopted a Workmen's Compensation Act, and that both Wisconsin and Minnesota are considering compensation as the only feasible solution of this problem, the Chicago Federation of Labor and its representatives on the commission have taken a decided stand that the abrogation of the employers' defenses must precede any bill providing compensation.

"It is evident from the letter which the Federation submits that its officers are not only unfamiliar or unmindful of the economic waste involved in any employers' liability system, but that they have no knowledge of the total inadequacy of such a system, even when extended by such serious modification of the employers' defenses as the American Federation of Labor advocates.

"An employers' liability law meets none of the prime necessities of definite compensation, immediately and automatically paid. Under it every case is a gable." Signed by the six "employer" members of the commission of twelve, Illinois Employers' Liability Commission.

German Experience

Again, Major A. R. Piorkowski, representing the Frederick Krupp Company of Essen, Germany, and speaking for the German system:

"The German Accident Insurance had its predecessor in the Liability Law of 1871, by which the operators of industrial establishments were liable for the accidents caused by them. The injured workmen had to bring proof that the operator caused the accident, and the amount of compensation was determined by private societies. It is evident that such an institution could satisfy nobody. The consequences were long drawn out and costly law suits, by which the contrasting interests of employers and employee were glaringly brought to light.

"The more law suits between both classes, the more hatred and the less understanding there were for what was mutual in their interests. Employers, employees, and the Government looked eagerly for a better solution of the problem. Germans have been called a people of thinkers. They thought, and understood why the liability law did not answer the purpose, did not work for peace between capital and labor. It worked unjustly toward both of them. Therefore, the only logical and just way to compensate for the injuries done is by insurance.

"In 1900 this law received its present shape. All workmen and administrative officers—the latter, provided their annual earnings do not exceed 3000 marks —are insured against the results of accidents in the course of their employment if employed in mines, factories, and similar establishments specified by law. In case of disability, compensation is rendered from the beginning of the 14th week after the date of the accident."

Criticism of State Insurance

If any gentleman present imagines that the German system would be a success in this country, let me quote from *The New York Commercial*, of Friday, Oct. 20, 1911—under the heading, "Liability Men Criticize State Insurance System."

"Nearly every speaker, alluded to a recent review of the German state-insurance system, written by Dr. Ferdinand Friedensburg, who has recently retired after 20 years at the head of the senate of the imperial insurance office of the German Empire. Dr. Friedensburg does not find the German system, as it has worked out in practice, by any means ideal but does not condemn the principles underlying the workmen's compensation for accidents.

"Dr. Lott quoted him as saying that charity crept in and corrupted the system at the beginning;" that "employers do all that is possible to escape their burdens, which they feel to be unjust and in vain enormous sums are annually exacted from them in fines," that "industrial unions and insurance institutions have been repeatedly on the brink of bankruptcy."

"Dr. Friedensburg points out that the excessive cost of the insurance system, which is one result of the degradation of the system into charity, is complained of by employers, and that state insurance therefore, reacts injuriously upon Germany's industry."

He says: "As a result of the costs of insurance which have gradually become monstrous, German industry is put at a disadvantage and is hampered to the extreme in its competition with foreigners."

Caused Rise in Prices

Indeed, Dr. Friedensburg makes the astonishing statement that the German system of workmen's compensation is held responsible for the marked rise in prices which is felt to be oppressive by all classes of the German population.

Mr. Wolfe is of the opinion that whether the state will undertake the employers' liability business to the exclusion of the companies depends upon the attitude of those companies and their disposition to coöperate with the state in the solution of the economic problem. He said that employers' liability insurance represents more than one-half of the entire liability business transacted and consequently the question of state insurance is of vital interest to the underwriter.

While heretofore the question may have seemed to the underwriters a fad or a form of socialistic doctrine and an interference with the right of contract, a discourager of thrift and an encourager of malingering and intentional accidents, public opinion is overwhelmingly in favor of entering the cost of human accidents as a part of the cost of production, and the underwriters, in the opinion of the speaker, must face the situation accordingly.

Mr. Rowe stated that obviously the trouble with state insurance, viewed from an impartial angle, would be the mixing of politics with it. "Workmen's compensation insurance," he said, "can only exert its effect as a blessing if free from all exaggeration and particularly from the conscious or unconscious love-making with the "lower classes."

"Such insurance," he said, "must be issued by an independent institution free from all partiality."

Choice of Two Methods

Here then are introduced two methods, one the "Employers' Liability Act," which has been discarded by practical men, the other the "Workmen's Compensation Act," now before us, and between these two we are called upon to choose.

Your committee urges a Workmen's Compensation Act as best fitted, by experience and practice, to the mining industry.

The Liability Act appears, to your committee, to be unjust and unreasonable, in principle and in practice—the very mention of it suggests lawyers, courts, delays, annoyance, strained relations, expense to employers and loss to workmen. In one word it means "fight." The Compensation Act means "payment." The former is an unknown quantity; the latter is a fixed principle known and computed in advance, and provided for. The record of the Liability Act is said to be about 50 per cent. adjustment—the Compensation Act means 100 per cent. adjustment.

Adjustment under a Liability Act is reported, by one large coal operator, to be injurious in 80 per cent. of the cases in a large disaster, in that it would shower money into the hands of the inexperienced, where value is unknown, and where money and widows are soon parted.

Liability-law adjustment, in the judgment of the committee, is a mistake, is uncertain and unreasonable, is an injustice to all concerned, and is prejudicial to all the best interests of a miner's widow and children. It defeats a good intention, and does *not* insure the care, education and opportunities of life, supposedly vouchsafed to the husband and father, by a law which caused him to risk and lose his life in an honest belief, and a sincere endeavor, to provide for his family. In short, it looks as though the most ardent supporters of an Employers' Liability Law, are ambulance chasers, and those who could hope to profit by a disturbed condition, as between capital and labor.

Some Erroneous Conclusions

It is also conceded that labor is just as necessary for the maintenance of industry as any other commodity, and that the cost of compensation, as a fixed principle of industry, should be reckoned with in placing a price upon the finished product. Upon the grounds stated, we believe the Liability Act to be wrong in principle and practice, and that the injustice of it falls upon those who are least able to bear it on the one hand, and, upon the other hand, falls upon those who are supposed to be wealthy, but this supposition is based upon opinion thoroughly unfamiliar with the facts, and therefore incompetent.

Position of Mining Industry

The mining industry should stand ready to bear the burden of its own accidents—it should stand ready to pay a tax of one cent per ton of coal mined to meet the necessities of the case and to provide the necessary funds.

It should stand ready to have this fund administered wisely in the interests of the workmen and their families.

It has always stood ready to consider, and has introduced every known precaution to prevent these accidents, and to safeguard every man employed above or below the ground.

It considers all this right, reasonable and just, and that the best direction to move in, to accomplish the best results, is the passing of the Workmen's Compensation Act.

In the preceding argument we have referred to the best direction in which to move to accomplish the best results, and have clearly stated our reasons in favor of the Compensation Act. There is another important point to consider with reference to this Act, namely; the mining industry must give its best thought to the method of introducing and passing the Act, it cannot be left to the unfamiliar majority. The necessity for reasonably uniform legislation by the different States of the Union must not be lost sight of. Uniformity of legislation on all subjects of common interest is one of the most important questions of the times.

The necessity for careful study, for the wisdom which comes from the multitude of counsel, and for definite and determined action, is clearly evident.

The American mining industry should here go on record as favorable to that solution of this problem, which is right, reasonable and just to the industry, to the employer and to the employee.

A law that strikes at the life of the industry will be a calamity.

A law that does justice to employer and employee, that operates, and compensates, without delay, friction or loss, will be a blessing.

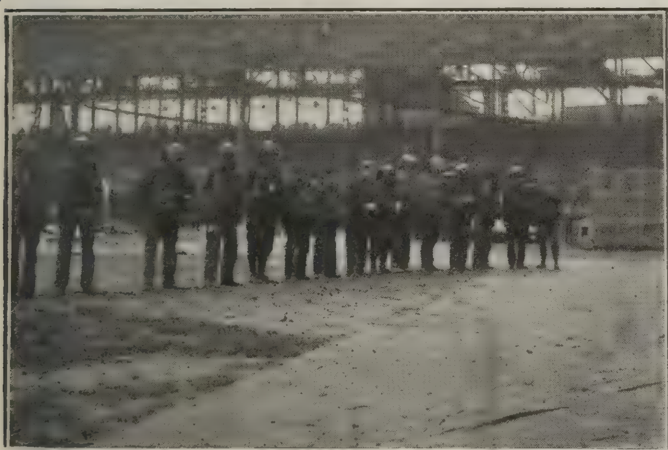
The Explosion at Bruceton Mine

By R. Dawson Hall

The Bruceton tests clearly develop the fact that under some conditions, an explosion may follow the return airway. The most clearly marked evidence of pressure was seen in a dusty part of the intake where there was a curve in the path of the explosive current.

An endeavor will be made in this article to treat the tests at the Bruceton mine in a somewhat more detailed manner than was attempted in the short description by J. T. Beard in the last issue. This article is to be regarded as supplemental only to his work and where details are missing, they can be supplemented by a reference to Mr. Beard's description.

The experimental mine is an honor to the Government's Bureau of Mines. Here are provided natural conditions, here all the conditions of actual work can be not only simulated, but actually reproduced. If a mine explosion occurs here, no specious critic can say, "You can do these things in a cylinder of boiler iron, but can they be done in a real mine?" The action of an explosion is a complicated thing; it can only be followed to its conclusions by actual observation in a mine where all the conditions prior to the explosion can be accurately predetermined—what doors were shut or open, what shot blew out, what powder was in it, how it was stemmed, what gas was present, what humidity prevailed and what air current was passing. Here stoppings and overcasts can be erected and their strength determined. One factor after another can be eliminated, till the basal actuating impulses of an explosion can be laid bare and their relative importance determined. No work of others can be duplicated here, for there is but one Bruceton. It will set the standards for all future work, until like mines are installed elsewhere.



Helmet Men Ready to Demonstrate Rescue Work

Showing Part of the Crowd at the Safety Demonstration

General Description of Mine

Bruceton is situated thirteen miles south of Pittsburg, on the Baltimore & Ohio railroad. The Bureau has there a mine, illustrated in the accompanying cut, which shows the whole development of the mine up to date. The main heading extends 715 ft. from the mouth. Three crosscuts connect it with the parallel airway to the left. The main gangway is open and unobstructed from end to end. The ends of both headings are 70 ft. clear of the last crosscut. The mine is faced immediately by a small spur of hill so that the flying débris resulting from an explosion is stopped before it can travel far. Fortunately, Bruceton mine has rural surroundings and no harm is likely to result from the spectacular explosions.

The main portal of the Bruceton mine is of concrete, well reinforced so that it can withstand all manner of stress, including upward and outward stresses which, in the design of most mine approaches, is not considered. The foundation is carried down to the Pittsburg limestone, which lies about 5 ft. below the Pittsburg coal. As shown, the concrete lining extends about 240 ft. in from the portal of the main tunnel.

The Recording Chambers in the Mine

On the left-hand side are two instrumental chambers, equipped by the Cambridge Scientific Instrument Company, of England, with pressure recorders which will continuously record the side pressure of the blast as it passes, showing on a chart, which revolves on a drum, the pressures at every interval of time. At these same stations are set wires from each side of the heading connected together across the roadway by a guncotton tie. This guncotton tie is burned by the blast as it passes so that an electric circuit is broken and the time interval is measured in the observatory on the hill.

In the airway, lying left of the main heading a sandbag stopping from 6 to 8 ft. wide, was piled at the edge of the oblique gallery. At the time of the visit two heavy canvas stoppings lay across the first crosscut, the second was completely filled with sandbags for 8 ft. of its length, the third, that is, the most remote, was open.

The Steel Dust Gallery

The steel dust gallery is as shown. It is made of half-inch boiler plate and is 102 ft. long and 6 ft. 4 in. in diameter. Beyond this typical explosions gallery is a movable section of 20 ft. followed by a 20-ft. concrete section covered by heavy plank and loaded down with dirt, so as to make it less likely that the steel section will have to bear strains beyond its strength. For about 200 ft. beyond the explosion door section, the gallery is extended underground to meet the airway. This 200 ft. of gallery is built of reinforced concrete. Two instrument chambers are set in the sides of this gangway, but they are not equipped with instruments, as funds at the disposal of the Bureau do not permit it.

Ventilation of Mine

There is a small blower fan near the steel gallery. It is a 36-in. Sirocco fan with 20-in. blades and was delivering 4000 to 5000 cu.ft. per min. at the time

the guests of the Bureau visited the mine, though it is competent to produce much more. A light corrugated-iron building covers the fan, so light that its destruction is assured whenever an explosive blast occurs. It may be added that the steel gallery was closed by a door and two light wood doors covered the opening to the airway though the large sandbag stopping further in made them useless.

The Inspection of the Mine

The visitors went in at the portal of the main heading and by the light of electric lamps passed on to the end. On either side were seen shelves, which were really mine rails, set on edge measuring 2½ in. by 4 in. These were supported by bolts projecting from the concreting or

An Irksome Delay in the Proceedings

The visitors were disposed on the hill back of the mine so that they could see the portals of the main heading and of the steel gallery. The location was not favorable as the rain had made the newly planted wheatfield undesirable for walking.

One shothole was charged, it appears, with 2 lb. of FFF blasting powder, with a tamping of 6 in. of fireclay, the whole being set within an inch and a half pipe to insure a blownout shot. The men left the mine and the circuit which was expected to fire the shot was closed. Nothing resulted; not even the sound of a shot could be heard. The miners of the Bureau again entered the mine and connecting the wires of the detonator to discover if the lead wires were short-circuited. In the hurried work of the last few days this feature was overlooked. A new circuit was then laid into the mine and this time, to make assurance doubly sure, the last hole was charged and the three holes connected in parallel.

The Explosion

There was no failure that time; all three exploded together, as has since been learned. A burst of devouring flame enveloped the little strip of woods, burning leaves at the top of the highest trees. A loud report, heard over five miles deafened the hearers, and a rain of sandbags, planks, shelves and what not, ascended 50 ft. in the air where they could be

President Taft; Governor Tener, of Pennsylvania; Secretary of the Interior Fisher, and Doctor Holmes Viewing the National Mine Safety Demonstration in Pittsburg

the coal as the case might be. They were covered by dust but it did not appear that there was much dust to be seen. The floor was clean. In fact, there was only 1 lb. of coal dust to the foot-run in the heading. At the end of the gangway, three holes had been drilled in the coal. Each hole was large enough to hold a 1½-in. pipe. The holes were drilled about 3 ft. above the floor in a horizontal line, and extended 4 ft. into the coal.

The concreted portion of the airway entry and of the oblique gallery had shelving of like character to that in the main entry, but the dusting only ran ½ lb. to the foot-run. No dust was distributed in the steel section. Some dust holders of the bookcase type ("transverse shelving") were put in the first crosscut between the main entry and its airway.

nected another line of wires with another shothole of like charging, and came out and gave the signal. Another moment of tense suspense—and nothing resulted. The people were wet and cold and they were afraid of missing the train, and considerably over one-half, among whom were many, including the helmet men, who had come hundreds and thousands of miles to see the explosion, left the field.

It was the opinion of the Bureau officials that there was a short-circuit or a grounding due to the trampling of the people who went through the mine. The wires were only properly guarded where set in a pipe within the concrete and were not protected against injury where the headings were not cemented. No test apparently was made before con-

plainly seen in the brilliant glare. The flame crossed the ravine in front and licked up the vegetation for a distance of 200 ft. A mine car, with its light weight of gravel, weighing about 2000 lb., stood about 20 ft. from the mine. It was lifted off the track, thrown bodily over the rock dump; it somersaulted several times, and struck the ground 200 ft. from the mines to make two more complete somersaults clear of the ground before it lighted with its wheels solidly embedded in the sod. Another car, with its load of coal, weighing two tons, was 75 ft. from the main entry and was lifted off the track and moved 20 ft. The fan house was demolished and the explosion relief-section unroofed. The sight of these missiles barely 50 ft. away and 50 ft. above ground warned the people to run and,

though no one was frightened, there was a politic retreat in which at least one man was knocked down.

After the Explosion

A rough survey was made of the outside, the openings were closed up and the mine left for the night. A later investigation shows that the stopping in the airway was entirely removed and blown out through the doorways, the wood doors swinging open without injury. The sand bags were found strewn in the mouth of the airway.

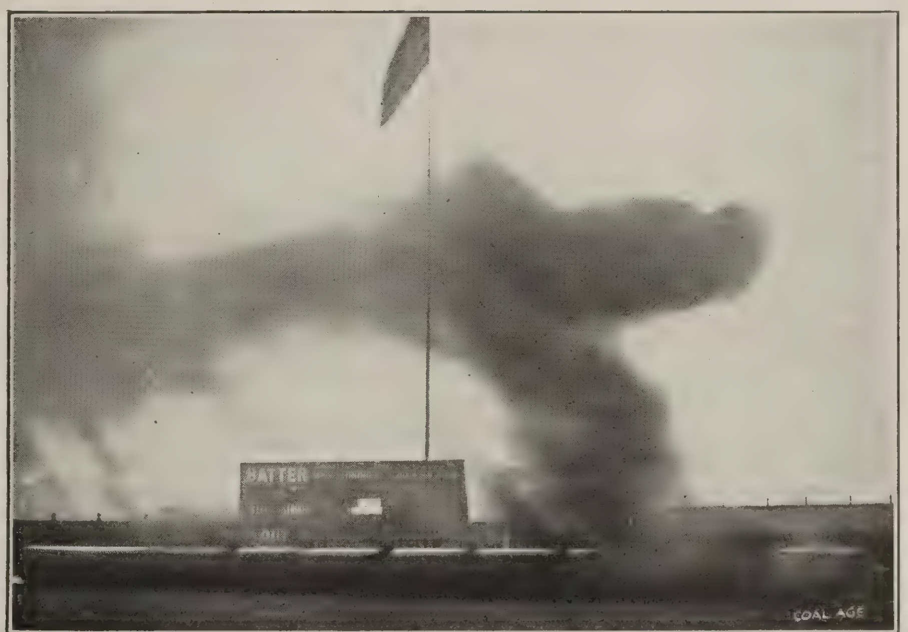
It must here be stated that the fan blew air directly into the steel section. This air passed up the oblique gallery to the parallel airway, up that heading to the last crosscut, and thence to the main heading and out. The shots, therefore, were fired into still air, the blast having to travel 70 ft. before a current of air was met. The explosion appears for the most part to have followed the return current. It was here that it had dust to feed on. There was no dust in the parallel entry, inbye of the first crosscut. Nevertheless the explosion crossed over to the airway at the inbye crosscut. There was evidence of coking of dust on both sides of this connecting airway and the coal had a bright silvery metallic luster in places, very different from the black luster of the unaffected coal, and strongly contrasting with the dull-looking face where the coal had been exposed to smoke.

Waiting For the Coal-dust Explosion in Bruceton Mine

The Fire Dies in the Intake

Though there was a small fall of draw slate in the airway, there was no evidence of violence between the first and last crosscuts and it is probable that the blast soon died out on the intake as it had little to feed on, soon burning or depositing what it had and finding no more. The unused "bookshelf" dust holders in the face of the airway were standing almost without distortion, though built in a way that makes them easily deformable.

To return to the blast passing out at the main entry, it passed the second crosscut without disturbing the stopping, but it blew through the first breakthrough where nothing but a canvas intervened. At the end of the concrete tunnel, the wires for shot-firing emerged and at that point a notch had been made in the rib. There was a plug set in the pipe at the time of the explosion and apparently a vacuum action removed the plug which was found lying loose in the notch just mentioned.



Showing Coal-dust Explosion in Forbes Field

The Concrete Tunnel Is Severely Cracked

At the point where the blast made the turn to the oblique gallery the force was perhaps the most apparent. In concreting the tunnel every effort was made to put the grout up to the roof so that the concrete would be in perfect contact. This was not always successfully accomplished, with the result that both in the explosion of the 24th and 30th, there were places where the concrete lining was lifted and badly cracked. One big crack showed at the sharp angle where the right side of the airway and the left side of the oblique heading intersect, using right and left in the sense of an observer going to the outside. In this crack a plug of wood was so forcibly driven it could not be pulled out. The concrete had evidently been lifted and in settling again had retained in place, not only this piece of wood, but some pieces of bag and twine as well. In one place the reinforcement was disclosed.

Pressures and Velocities

At present writing it is not known what pressures and what velocities were reached. It will take some time to ascertain these, as they demand some careful calculation, but in the explosion of October 24, the time of its passage from the face of the main entry to the inbye instrument station was 1½ sec., and the mean speed 406 ft. per sec. There is no question but that this speed was very much exceeded near the instrument mentioned and was not nearly reached at the point of ignition. Between the last two instruments the speed averaged 1900 ft. per sec., which accords well with the speed recorded by J. Taffanel and W.

E. Garforth, at the Liévin and Altofts galleries, respectively.

The pressure measured at the first explosion (that of the 24th) at the outbye station was 41 lb. per sq.in. That exhibited at the inbye station was over 50 lb., that figure being the record limit of the instrument. The pressure rose suddenly to that figure and it is likely that the actual pressure was much higher. As the first explosion was probably as severe as the exhibit explosion, and of like character, and did as much damage, it seems that the pressures must have been about equal on the two occasions. There will be several who will fail to accept such results as correct. The pressures surely should be greater than three atmospheres. It is probable that the pressures normal to the direction of the air current are small comparative to the pressures produced by the direct blast despite the general law of gas pressure, and it is possible that in the small fraction of time during which the pressure continues, the instruments lag in recording it, but it is not safe to make that statement with any assurance.

Action at Face of Main Gallery

There were long filaments of dust hanging from the roof and coal in the *cul de sac* beyond the last crosscut in the main entry. These were not visible further out. Evidently, the speed and force of the blast were not severe in the end of heading and probably the combustion itself lagged in the absence of a feeding current of air.

The deductions are as follows:

(1) The explosion near the point of ignition did not do much damage. It is only putting it in another way to say that the speeds and normal pressures were lower at the point of ignition than at the end of the assisted travel of the explosion.

(2) The explosion followed the coal dust even where the coal dust was placed along the return.

(3) There was no evidence of extended explosive action toward the intake where the intake formed a dustless zone. But it must be remembered that the explosion probably entered the dustless zone with only about 70 lb. of coal-dust fuel. Had it broken through 200 ft. below into a dustless zone, the result might have been different.

(4) Gas does not need to be present to act as a medium to ignite coal dust. There was no gas in the Bruceton mine.

(5) The dusty intake induced at least as severe an explosion as the dusty return.

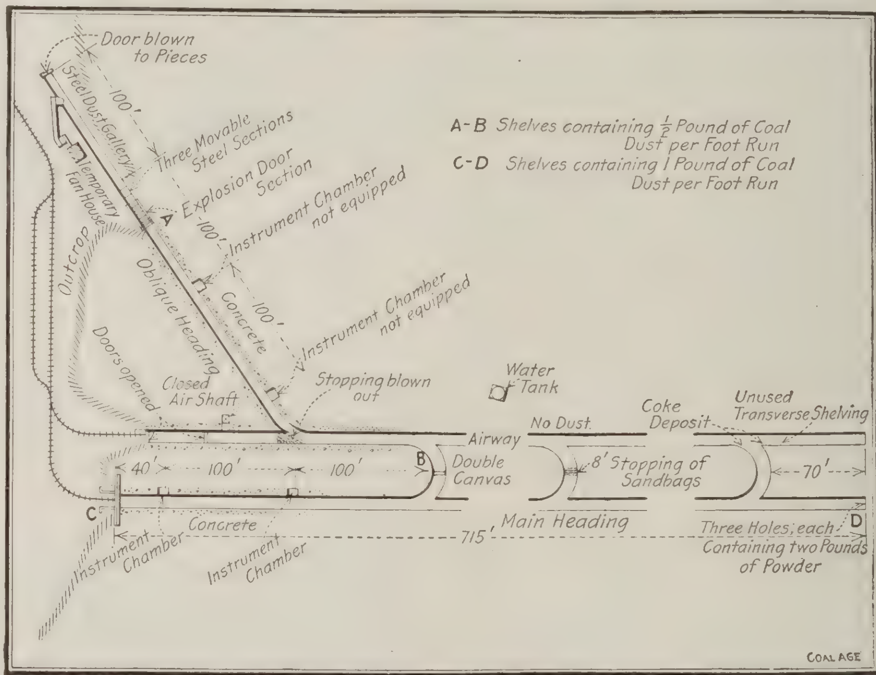
(6) Stoppings of unusual strength are needed for resistance to explosions.

The explosion confirms rather than establishes what has long been held: that an explosion under favorable circumstances will follow the return, and under unfavorable circumstances will not follow the intake; that the explosion will not traverse a dustless zone in the absence of gas, especially when the dust content of the blast is low and, moreover, that the initiating point of the explosion is often accompanied with as little flame, as little force and as little speed as any portion involved in the catastrophe.

The intention is to install a Jeffrey fan, capable of giving a speed of current of 2000 ft. per min., and thus to test the action of high-speed air currents. This fan will be reversible so that the explosion may be toward the intake as well as toward the return.

It is not likely that the humidity of Monday checked the explosion in any way. The value of humidity is not to dampen dust, but to keep it damp. Dust does not take moisture from the air readily, and it is fair to assume that the dust used was absolutely dry. It was prepared from Pittsburg coal, ground down so that 95 per cent. would go through a 100-mesh sieve.

It may be suggested, finally, that a favorable vantage point be selected for a view of the explosions and that all trees interfering with the view be removed. There is no question but what, if the experiments are continued, outraged nature will attend to the removal of the trees, but it would be better to forestall this result and make the view less restricted. If some arrangement could be made to provide a substitute for the mellowed mud of a recently plowed field, the thanks of the public would be freely accorded to the bureau for this improvement.



New Map, Showing Bruceton Mines Just Prior To Explosion of Oct. 30

Ammonium Nitrate Explosives

The consumption of ammonium nitrate explosives is steadily increasing both in this country and abroad, especially in the mines of Austria and Germany. Favorable conditions for the manufacture of these compounds also seem assured, since it has been demonstrated that nitric acid and various nitrates can be produced from the nitrogen of the atmosphere. For a time recently, fears were entertained regarding the production of all explosives except chlorates and perchlorates because of the impending exhaustion of the Chilian saltpeter deposits and the consequent rise in the price of nitric acid.

By ammonium nitrate explosives are meant those which contain ammonium nitrate as their chief ingredient, and not as merely a contributing addition. This class in common with other permissible explosives possesses qualities of great merit from the standpoints of safety in handling and transportation, and security against ignition of gas. Ammonium nitrate compounds are detonated only by a strong initial impulse, as compared to that required for dynamite, and are practically flameless. Unlike dynamite and some other permissible explosives, the gases formed are not as a rule noxious or toxic. In the event of their incorrect composition, however, these compounds may give off nitrous gases, which are particularly treacherous and far-reaching in their effects. The chief feature in this class of explosives is the suppression of the flame in blasting.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of COAL AGE, *we will print 6000 copies. No copies will be sent free regularly. There will be no back numbers. The figures which will be shown here each week will represent live, net circulation.*

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

Contents

COAL AGE

The Hard Coal Trust

The case of the Federal Government against the anthracite coal-carrying railways, or the so called "hard-coal trust," has been reopened by the presentation of briefs before the Supreme Court of the United States. The Circuit Court, which tried this case last year, sustained the prosecution in only one of its several charges, and the whole case has been appealed substantially as it was originally presented.

It is generally known and acknowledged that the several defendant railroads do, in fact, control their affiliated coal-mining companies through stock ownership or otherwise; that a combination of their interests was effected by means of the Temple Coal and Iron Company, which the specified companies established as copartners; and that the practice of taking over the output of independent mines at a uniform rate is in general operation. Whether or not these matters, as well as those set forth by three other charges which have been entered, will be judged illegal and in restraint of trade, will doubtless soon be determined.

The effect of a decision adverse to the coal and railroad interests involved, is a matter of conjecture, but it is interesting to recall that at one time the conditions under which anthracite coal was mined and marketed were similar to those which prevail at present in the bituminous field, and that these conditions made for waste and industrial uncertainty, although they did not make particularly for low prices.

The present coalition of interests in the anthracite field was not conceived as an altruistic measure for preserving the country's resources from waste; but neither was it launched, full grown, with the object of squeezing an unmerited revenue from the public purse. Like many large industrial enterprises it has grown up gradually through efforts to meet existing conditions step by step. The small operator with a short-term lease wasted 1½ tons of coal for every ton sent to market. The large company, with adequate capital and extensive holdings, has been able to reduce this waste by half.

A study of the conditions in the anthracite field by no means supports the idea that the public is being robbed. An immense amount of money has been invested in preliminary deadwork and costly equipment, all to the end that reckless spoliation and extravagant methods of mining may be eliminated. By this the public eventually profits no less than the operator.

It is, however, quite possible that the present desirable state of affairs in this field, from the standpoint of conserving its resources and ameliorating the conditions of mining, humanly speaking, as well as in a commercial sense, can be maintained with the industry on a basis more severely competitive than at present, and should the necessity arise, it is to be hoped that this will be the case. The large unit has definitely proved itself to be both necessary and desirable, but the amalgamation of large units may yet be shown to be neither.

The Preparation of Coal

There is little mutual comprehension between the anthracite and bituminous fields. Both are enlarging and developing without much help from the other. At times it seems as if there was more inspiration received in Pittsburg from Cardiff than from Scranton, so far is the northeastern field separated from the main Appalachian development. It is hard to explain why this should be.

In the matter of preparation of coal in the anthracite region, the large sizes are cleaned wholly by visual methods, the smaller sizes being cleaned by visual, superficial and physical processes. The superficial classifiers cover such separators as depend on the fact that slate slides on a chute with more friction and less speed than coal. The ability of clean coal to jump a gap into which dirty coal falls is due to the greater speed it attains on the chute, which lengthens its trajectory. Similarly the coal in the spiral picker runs so much faster than the

slate that its centrifugal tendency, so called, makes it rise up a slight incline and leave the inner spiral for the outer.

The only true physical process, which is based on the internal composition rather than the external appearance, is some form of washing device. Such devices in the anthracite region are used for all sizes from buckwheat to egg inclusive with diameters ranging from 5/16 to 3¼ in. The coal of the anthracite region is not often subjected to chemical analysis, but to purely visual tests, so much slate and so much over-size or, under-size being permitted in the sample taken.

On the other hand, in the bituminous region, except for the washing of slack, there is never anything but a picking belt or table. Yet the test of the coal is always chemical as far as it is tested by any recognized method. Physical preparation more nearly approaches the chemical than any other. It alone considers the whole mass of the coal body and overlooks its outward appearance. Some pyrites is crystalline and is readily rejected, some is colloidal and looks harmless in comparison. It may be regarded as being in passable proportion, because not so easy to distinguish.

It would appear, offhand, that a coal to be visually tested like anthracite, should be visually prepared, and that a coal chemically tested should be largely physically prepared. Though in any case the combination of methods, ocular and physical, would be better than either.

Counting the Cost

The fact that the present agreements between operators and mine workers in both the anthracite and the bituminous coalfields of this country expire simultaneously, March 31, 1912, seems to be obtruding itself more and more on the public consciousness. From increasingly diverse and widespread sources come indications of awakening interest in this matter. Many who are more immediately concerned have had the fact in mind for a long time and doubtless, for some, it has formed the basis of conjectures and plans, during the greater part of the past six years. Recently, the union locals have been considering and formulating their proposed demands and the operators have been storing coal and taking other precautionary measures.

Without attempting to discuss the present status of the controversy, the probability of its ultimately developing into an actual and momentous issue, or the strength and attitude of either side in this latter event, it may be pertinent to suggest that the time to count the cost is preferably before and not after a conflict.

The cost of the Welsh collieries strike which lasted the greater part of the past year and terminated without a decisive victory for either side, has been estimated at $15,000,000. Whether or not this figure is accurately determined is a matter of secondary importance in comparison with the obvious fact that the cost of such a strike is enormous.

Broadly speaking, the cost of an industrial struggle of this kind may be measured by the losses sustained, taking normal working conditions as a basis of comparison, and by the expenses incurred, which are, in a final analysis, productive of neither useful work nor a valuable commodity. To enumerate all of the various items which go to make up this total cost would be a difficult and intricate matter, so complex and far reaching are the interests concerned, but a few of the more easily apparent expenditures and losses may serve to indicate the magnitude of the whole.

Of prime importance to the workmen is the loss of their usual earnings. This is also, almost in its entirety, a loss to the various communities and the country at large since the cost of subsistence for the men and their dependent families during the period of enforced idleness, whether defrayed by the savings of the men themselves, the contributions of their confederated fellow workmen, or the extended credit of landlords and tradesmen, represents a reduction in the aggregate wealth of the country; and the increment of national wealth normally accruing from the miners' labor is likewise lost.

On the other hand, the owners and operators must inevitably regard with particular concern, the fact that the total amount of capital invested in the idle portion of the industry is deprived for a time of its usual and expected earnings. This applies not only to the mining operations, but also in a somewhat less degree, to all the various transportation, sales and distributing interests which are involved, because the reduction in their expenses by no means corresponds to the reduction in the volume of their business, and because a large percentage of their capital, if not the entire amount, is dependent on this business for its earnings.

Then there are the many actual expenditures which from the standpoint of usual working conditions yield no permanent or valuable return. The maintenance of the organized executive, clerical and other forces of the various companies is at such a time largely a dead loss. Additional police protection is an important item of expense to both operators and State. The cost of employing firemen, pumpmen and other unproductive labor is considerable. But lacking these measures, the almost incalculable losses consequent upon drowned-out mines, abandoned machinery and the destruction of other valuable property must be taken into account; and at best, the impaired condition of plants by reason of disuse and neglect will represent no inconsiderable expense.

To the foregoing may be added a great number of other items, all more or less susceptible of being expressed in terms of dollars and cents, but whether so expressed or not, definite and substantial contributions to the total cost. The migration and emigration of the laboring element whereby organized forces of experienced workmen are broken up and disbanded; the lawlessness engendered by idleness and want; the baleful effects of strife, riot and bloodshed; the insiduous degradation of the whole community; are a few such items.

Beyond doubt, if several hundred thousand men and several hundred million dollars are kept idle for any great length of time, the cost is bound to be prodigious. The important question then becomes, not how much this cost will be, but how may it be avoided. Nine years ago arbitration was scorned and scoffed at by many operators and a multitude of miners, but it has since been admitted to possess merits; and in these days of conservation, strikes and lockouts have come to seem particularly crude and wasteful means for the settlement of a dispute.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

Experiments have shown that a 10 per cent. greater weight of briquets than of lump coal can be stored in a given space.

The motto of the H. C. Frick Coke Company should be the guiding principle of all mine foremen: "Safety the First Consideration."

The increase in temperature proportionate to the depth attained in deep mines is due to the secular heat of the earth, the presence of highly pyritic or carbonaceous shales, or the percolation of warm springs.

Hoisting rooms and power plants should be well supplied with metal cans for holding greasy, dirty waste. They should be emptied frequently as an accumulation of such material is a possible source of fire.

Experience has shown that non-mechanical storage plants are economical only for small installations since their cost of operation and maintenance is high, the amount of breakage is large and rescreening is difficult or impossible.

When quick-burning briquets are wanted remember that large briquets are harder to light than small ones, and that inorganic binders tend to make the briquet slow to fire. An increase of the inorganic matter in the slack also retards combustion.

Where there are dangerous accumulations of gas, in mine workings or the gob, which cannot be removed by the air current, boreholes put down from the surface will allow it to escape, thus rendering safe what would otherwise be dangerous working places.

Coal companies should furnish all of their mine superintendents with a classified monthly list of all mine accidents occurring in company mines; this is an inducement to greater forethought and care, the avoidance of similar accidents and the preservation of life.

With longwall mining, 6-yd. packs on either side of the haulageroad will add greatly to the safety of the mine and the workmen. Generally speaking, all packing should be kept within a distance of not more than 6 yd. from the face. Haulageroads should not be more than 30 yd. apart.

Signs, warning of danger, or suggesting correct mining practices, printed in different languages, and hung in conspicuous places in the mines, boiler rooms, pump rooms, and at the entrance of the mines are silent reminders of ever present danger which confront the ignorant or careless workman who is responsible for the high death rate of the American mines.

The reason that explosions in bituminous mines are more apt to occur in late fall and winter than any other season, is because the mines are drier in winter. Cool air contains less moisture than warm air, the warmth of the mine raises the temperature of the entering, cold, winter air, and as the air becomes warm, it absorbes water, thus taking up the moisture and depositing it outside.

In gaseous mines, where the system of ventilation is of the utmost importance, remember that the longwall system of mining greatly simplifies ventilation, as most of the air passes along the working faces in one continuous current, diluting the gases as they are given off. The absence of sharp turns and narrow passages reduces resistance and hence increases the efficiency of the ventilation.

The importance of immediately investigating the appearance of smoke in a mine is well illustrated in the Delagua, Colo., mine fire. Smoke was noticed in the return end of the crosscut, but the driver who first saw it did not stop to investigate; had he done so the lives of 79 men who perished might have been saved. Impress on all underground employees, the importance of instantly investigating the slightest indication of fire.

Calcium chloride is vastly superior to common salt for the treatment of dust on roadways or in rooms, as salt itself has no affinity for moisture, although the small amount of magnesium chloride contained in it attracts a slight amount of moisture, which is thrown off at every small rise in temperature above normal. On the other hand, calcium chloride holds moisture tenaciously even at a temperature above 350 deg. F. It is used in the tube system of New York City to reduce the dust and moisture.

Locked gates, placed at the ends of switchboards carrying high-potential lines, will prevent accidents, due to persons coming in contact with the uncovered conductors at the rear of the board. Rubber mats placed in front of switchboards are a means of preventing possible accidents. All mine transformer stations should be surrounded by a strong fence. If the transformers are placed on a platform above the ground, the danger of shock, from coming in contact with a high-tension wire will be eliminated.

Engine rooms should be equipped with water taps located at the intake opening near the sheave wheel. Such taps so located would be of inestimable value in case of engine-room fires. In order to overcome the strong drafts that often pass through engine rooms and fan slight fires into disastrous conflagrations, a door should be erected in the cross heading which connects the engine room with the passing branch. During the absence of the engineers from the engine room this door should be kept closed.

Experiments made at Pittsburg show that ordinarily, coal dust to be explosive must have originated from coal containing at least 10 per cent. of volatile matter. Dusts with a high percentage of volatile matter, other things being equal, are more sensitive than dusts derived from low-volatile coals. With coals that do not easily yield their gases, large intense flames are necessary to start an explosion. Experiments made by M. Taffanel have clearly shown that anthracite coal dust will not spread an explosion, which fact seems to prove that it is the volatile portion of the dust and not the fixed carbon present which spreads explosions.

Figures, issued by the Federal department of commerce and labor, state that coal mining in North America, in the 20 years from 1888 to 1908, resulted in the loss of 29,293 lives or 3.11 for each 1000 men employed. From 1896 to 1906 the average death rate, due to accidents in the coal mines of North America was 3.13 per 1000 men. During this same time the rate in the United Kingdom was 1.29; in France, 1.81; in Austria, 1.35; In Prussia, 2.13. The yearly average of fatal accidents in the entire North American coalfield has been about 3000 persons. In 1908, 567 persons out of the total 171,185 employees of the anthracite mines were killed. From 1896 to 1908, 46.6 per cent. of all coal-mine accidents in North America were due to roof falls, 25.2 per cent. were due to explosions and 12 per cent. were due to mine cars. During 1908, 10 children of 15, 14 and 13 years of age were killed in or about coal mines.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

W. Va. Fireboss Questions

Handling Mine Gases

Ques.—(a) Which is the most difficult to remove from the mine—firedamp or blackdamp? (b) Why is this? (c) Which, in your opinion, is the most difficult gas to contend with in mining? Explain fully.

Ans.—(a) This depends on the density of the gas with respect to its location in the mine. Blackdamp (carbon dioxide) is most difficult to remove from dip workings, and marsh gas is most difficult to dislodge from high falls or the face of a steep pitch. (b) Because the heavier blackdamp tends to fall back down the dip nearly as fast as the air-current can remove it; and, likewise, the lighter firedamp (marsh gas and air) tends to rise on steep pitches and high falls almost as quickly as the current can dislodge it. A strong current well directed by temporary brattice is required, in each case, to sweep away the gas. (c) The most difficult gas to contend with in mining practice, when it is present, is carbon monoxide (whitedamp); because it may be present in dangerous quantity, and its presence not be suspected before it has produced fatal effect.

Explosive Mine Gases

Ques.—(a) Name and describe the explosive gases usually found in coal mines. (b) Under what conditions do they become explosive and nonexplosive? (c) How are they generated in mines? (d) Where are they generally found and how can they be expelled from the workings? (e) What effect have these gases on the health and safety of the workmen?

Ans.—(a) The explosive gases found in coal mines are marsh gas, carbon monoxide, and sulphureted hydrogen. (b) These gases become explosive when mixed with air in the proper proportions; the explosive mixture, however, is rendered nonexplosive by the addition of sufficient quantities of such extinctive gases as nitrogen or carbon dioxide. Carbon monoxide is also nonexplosive in the absence of moisture (dry air). (c) Marsh gas issues from the pores of the coal and contiguous strata, in mines where it exists as an occluded gas. Carbon monoxide is produced by the combustion of carbon, in any form, in a limited supply of air, which makes the combustion incomplete; it is also formed, in some mine explosions, by the reduction of carbon dioxide in presence of incandescent carbon or coal dust. Sulphureted hydrogen is formed in mines by the action of the air and water on the iron pyrites (sulphur balls) in some coal, or is liberated from mine water containing sulphur. (d) The several mine gases are found in those parts of the mine where they are generated in considerable quantities, or where they accumulate by reason of their density with respect to air. Marsh gas is formed in largest quantity in new workings and freshly exposed faces of coal, or on the falls in abandoned workings, and in rise workings or at the face of steep pitches. Carbon monoxide is formed in abandoned workings and poorly ventilated places where slow combustion is in progress, or shots have been recently fired. Sulphureted hydrogen is formed mostly in low, moist places or swamps where the coal contains much sulphur, and in the region of drainage sumps or pump lines. All these gases are removed from the mine by an ample and well distributed air-current. (e) Pure marsh gas suffocates by excluding oxygen from the lungs, but when diluted sufficiently with air, it produces no ill effects. Carbon monoxide and sulphureted hydrogen are both extremely poisonous, but fortunately do not often occur, in mines, in quantities to prove dangerous.

Interesting Questions

Duties of a Mine Foreman

Ques.—What are the duties, in general, of a mine foreman?

Ans.—The duties of the mine forman are to devote his entire time to the supervision of the operation of the mine of which he has charge; to personally direct every branch of the work; hire and discharge the workmen; inspect daily all ventilating, hoisting, haulage and pumping or drainage machinery and appliances. To inspect personally, at least each alternate day, as far as possible, all working places, airways, roads and travelingways in the mine, and make the necessary air measurements to determine that the required quantity of air is passing in each split; to remove, or cause to be removed, all dangers as quickly as such are reported to him or found to exist in or around the mine. In case such danger cannot be promptly removed, it is the duty of the mine foreman to see that suitable danger signals are placed in conspicuous places so as to warn all persons of the danger; or, if necessary, to withdraw the men whose lives or health would be endangered. In case of serious accident to workmen, the mine foreman must attend to their prompt rescue and removal, and see that the injured receive proper first-aid treatment and care till medical help arrives. He must report such accidents to the district mine inspector, attend all inquests, and give the testimony required.

Hangfires in Electric Blasting

Ques.—Explain the three conditions that may cause a shot to hang fire in electric blasting in mines.

Ans.—Hangfires are less frequent in electric blasting than in blasting with fuse. They have occurred, however, with fatal results in many instances. There are different kinds of electrical fuses, chiefly classified as (a) *low-tension* fuses, in which the two terminals embedded in the exploding cap are connected by a metallic bridge of fine wire; (b) *high-tension* fuses, in which the terminals are bridged by a combustible having a conductivity such as to produce a somewhat high electrical resistance. It is possible when no detonator is used to explode the cartridge, that a hangfire may occur, owing to the powder being damp.

A misfire may result from the detonator not being of sufficient strength to explode the charge; and this may even cause a hangfire if the explosion of the cap has set up a deflagration of the dynamite, which may shortly detonate the charge. The same deflagration, followed by the detonation of the charge, may result from a damp, or poorly mixed, or insufficient priming. Bad electrical connections may delay the explosion by allowing the passage of a current of too feeble intensity, generating only heat enough to warm the bridge, and requiring a longer time to explode the charge.

The three conditions that may cause a shot to hang fire may be stated, therefore, as follows: (1) The powder used in the primer may be sufficiently damp to smolder or burn slowly. (2) The cap used to detonate the charge may be of insufficient strength. (3) Poor electrical connections may allow of the passage of a too-feeble current.

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

Y. M. C. A. Progress in the Bituminous Coalfields

It is now a little over nine years since the State Y. M. C. A. of Pennsylvania sent C. L. Fay into the bituminous coalfield to organize the Y. M. C. A. work. Greensburg was chosen as headquarters from which to launch this new enterprise. From the very beginning it met with hearty and immediate response upon the part of most of the operators and the men.

At first the volunteer form of organization was adopted, and 25 or more of these associations carried on a creditable work, the stronger ones finally developing into regular or secretarial associations. Among these were Greensburg, Punxsutawney, Latrobe, Monongahela, Ebensburg, Somerset, Myersdale, Export, South Fork, Patton, Barnesboro, Fayette City, Winburne, Philipsburg and Windber.

New Buildings

Some of these associations now own their own buildings or have the money with which to erect them. The plant of the association at Punxsutawney is valued at $50,000, Ebensburg, $35,000, Fayette City, $12,000, while Greensburg has had a bequest left to it of approximately $200,000. Indiana and Scottdale have recently conducted campaigns, securing $50,000 each. The Latrobe and the Monongahela associations are looking forward to the time in the near future when they will also have their own buildings. In the last nine years Connellsville, Washington, Du Bois and Clearfield secured their own buildings and Uniontown has a fund subscribed for a large building to be erected in the near future.

At the time the mining department was organized, none of the associations in this field were attempting any work for the miners. But today there is hardly an association in the whole bituminous coalfield that does not include in its program some special work among the mining population. Among these are Pittsburg Central, Johnstown and Washington.

Mining Classes and Institutes

The bituminous committee, through its secretaries, is reaching scores of smaller towns, where no large buildings have been erected or even association rooms provided. This is done by organizing mining classes and mining institutes, which meet in the school houses or hall or some place provided by the coal companies. It would not be overestimating if we were to say that no less than 600 men hold certificates today as a result of the classes organized through the help of the mining department of the State Y. M. C. A. Hundreds more have been greatly benefited and helped through the annual and monthly institutes. Some of the best papers that have come to our notice in recent years had been prepared and read by members of the Y. M. C. A. mining institutes.

Hundreds of non-English speaking men have been gathered into classes and taught English by means of the Doctor Roberts system. What this has meant to the individuals themselves and to the whole mining fraternity will never be fully written. For who can tell what new ideas, ambitions and resolutions have been let loose in the minds and souls of these honest, industrious, hard-working foreign miners.

First Aid

Take the first-aid work. In 1907, the Latrobe association began a regular monthly series of first-aid lectures, followed by demonstrations. Then they became a regular part of the monthly program in the local mining institutes. The mining department of the State Y. M. C. A. was, therefore, the pioneer of first aid in the bituminous coalfield. It paved the way and made possible the now sweeping interest in this humanitarian work so forcibly signalized at the first-aid demonstration at Forbes field, Oct. 31, 1911, by the Bureau of Mines and the other coöperating agencies.

Banquet of Wilkes-Barre Mining Institute

The present board of management is composed of John M. Jamison, Greensburg, Penn., chairman; L. C. Walkinshaw, Greensburg, Penn., recording secretary; Fridolin Miller, Greensburg, Penn., treasurer; other members are: George F. Huff, Greensburg; J. C. Stineman, South Fork; L. B. Huff, Greensburg; E. M. Gross, Greensburg; E. S. Wallace, Pittsburg; Austin Blakeslee, Du Bois; R. H. Jamison, Greensburg; A. P. Cameron, Irwin; F. C. Keighley, Uniontown; F. R. Lyon, Somerset; A. W. Calloway, Punxsutawney; F. M. Semans, Jr., Uniontown; W. W. Keefer; Pittsburg; W. R. Cal-

verly, Windber; Thomas B. Dilts, Greensburg, and E. E. Bach, field secretary, Uniontown, Pennsylvania.

Every coal company, every individual connected with coal mining, as well as everyone interested in the welfare of humanity in general, ought to encourage this unselfish and unexploited form of social service.

The Company House

The words of an acquaintance occur to me in this connection: "I arrange always to be in debt, so as to stimulate steadiness and frugality. When I can make a first payment on a bond or a house I do so, knowing that the instinct to save what I have will prompt me to prepare for the following instalments." He was a quiet man, no roisterer nor slave to social pleasures, probably as well known as any mining man in the anthracite region; but while it was true of him that debt steadied and balanced him, it is even more true of men of wild habits who are lacking in self control.

The company house in the company village, with company streets and a company store, does not furnish the needed opportunity for the expenditure of money in desirable ways. The man, who can buy no land, who can build no house, who expects to move any day, has no incentive to buy except to gratify the impulses of the moment. In fact, to him money loses much of its real value. He desires to get away, if only for a day from that undesirable place. He does not call it a home.

The Problem of the Company House Is an Open One

It must be confessed that it is a problem what the coal corporations can do toward the housing problem; if the companies build their own dwellings, the men are listless and their work is irregular; if the company waits for the town to grow, the increment of tonnage is painfully slow and the profit distressingly small.

On the whole it does seem that the better plan where there is a village nearby is to put the money often spent in company houses into the plant. Or again it is better where good rates can be secured to haul the men at a low figure several miles over the railroad to their work as the Consolidation Coal Company is doing at some mines in Maryland. The advantages of life in the larger villages, in no "one man's town," are always appreciated and preferred to life in the company town. In the neighborhood of Sligo, Rimersburg, Oak Ridge, New Bethlehem, Du Bois and Reynoldsville, Penn., to mention a few instances coming readily to mind, men frequently travel three miles, to and from their work, solely because life in those larger villages appeals to them. Some walk, some drive. In the last two cases mentioned, longer journeys, yet, are made on street cars.

The incentive to save, to form part of a self-made, self-advancing community provokes sobriety, steadiness and frugality. The presence of sober, steady, frugal men is a nucleus around which others of like kind can be gathered.

The Difficulties Surrounding the Company Town

The dominant note of the company town is coercion. It is not the dominant note so much because of the frailty of the operator but because coercion becomes almost necessary under the conditions obtaining. He must, for the safety and success of the community, keep out speakeasies and questionable characters. He must assume that dominance which inevitably arises from keeping, in close propinquity to his operations, the men to be employed therein. Moreover, the landlord must to a degree supervise the actions of the tenants in his houses and on his property.

His difficulty resembles in many ways the still unsolved domestic problem. The best workers refuse domestic service because it involves a dominance in matters which the individual regards as his inalienable personal rights; the householder must, however, retain such dominance because of the close personal association resulting from such service. If a town is built it must be policed in some sense by the operator, and when it is so governed, it is a corporation town and in some ways not desirable.

Difficulties Resulting from the Sale of Small Holdings

It is possible to build a town and sell lots around it with restrictions on the sale of liquor, but these restrictions, as far as speakeasies are concerned, are largely inoperative. A freeholder cannot be ordered out like a thirty-day tenant and a case against a man running a speakeasy for foreigners only, is hard to prove. Moreover, the company consenting to sell lots is then suspected of desiring to sell them and of discrimination in apportioning work to purchasing leaseholders and, even if discrimination is not desired, the denunciations of the company by a purchasing leaseholder on his discharge would be reëchoed by the nonpurchasers till discrimination unfailingly resulted.

And if the corporation builds a little town and lets others sell to the company employees, the corporation may be hampered in future unforeseen development; the presence of speakeasies and saloons may embarrass its operations and the time may come when the preference for

C. E. Tobey, President Scranton Y. M. C. A. Mining Institute

S. J. Phillips, Secretary Scranton Y. M. C. A. Mining Institute

J. H. Dague, Director Association of Scranton

noncorporational houses, shanties or huts, may make the company regret it ever built a single tenement. To keep its tenements full, discrimination naturally results.

On the whole, it seems that, whether saloons are few or many, speakeasies thriving or nonexistent, despite the discouragements of hampered development, the company usually gains by not dabbling too freely into the private life of its employees, even in the most disinterested ways. The best of men dread the eye which follows them night and day.

Anthracite First-aid Teams in Competition at Shamokin, Penn.

Labor and Wages

The most interesting question in connection with employment of labor is whether or not wages are increasing. A man may receive today \$20 for a week's work, with prices of food and commodities high. The same workman 20 years ago receiving \$15 per week, with low prices, might have fared better, so far as the general purchasing power of his earnings is concerned. Another point to be considered in the wage question is the "lost time" of workmen. A man who receives \$5 per day and works half of the time is only a little better off than the workman who is employed full time at half the wage. Such modifications of the wage question have greatly puzzled economists and statisticians in their efforts to ascertain and compare average wages today with earnings of workmen in the same industries years ago.

The percentage of increase of wages in general, from 1860 to 1891 is shown by the report of the Senate Committee on Finance, the wages for 1860 being considered as normal, or 100. On this basis, wages in 1840 stood at 87.7, 100 in 1860, 152.4 in 1866, 160.7 in 1891. Since 1891 there has been a steady increase so that at the present time the average of wages for all occupations is higher than at any time in the history of this country. It is also true that since 1860, the hours of labor have been reduced 10 per cent.

The workingman today demands not only the necessities of life, but something beyond,—a surplus which shall go to the support of his spiritual nature; that is, not merely sufficient food, a dwelling and a variety of clothing, but opportunities for reading, amusement, recreation and, above all, a better chance for his children. He desires to surround himself not only with necessities and conveniences, but demands a fair proportion of the luxuries of life; and every right-minded person must admit that this modern demand of labor is a proper contention.

The assumption of the present-day workman that he is more than a human machine is based on the soundest of democratic principles; the resulting change that is gradually taking place is sure to make wage-earners (skilled and unskilled) more valuable and intelligent citizens.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Strength of Stoppings

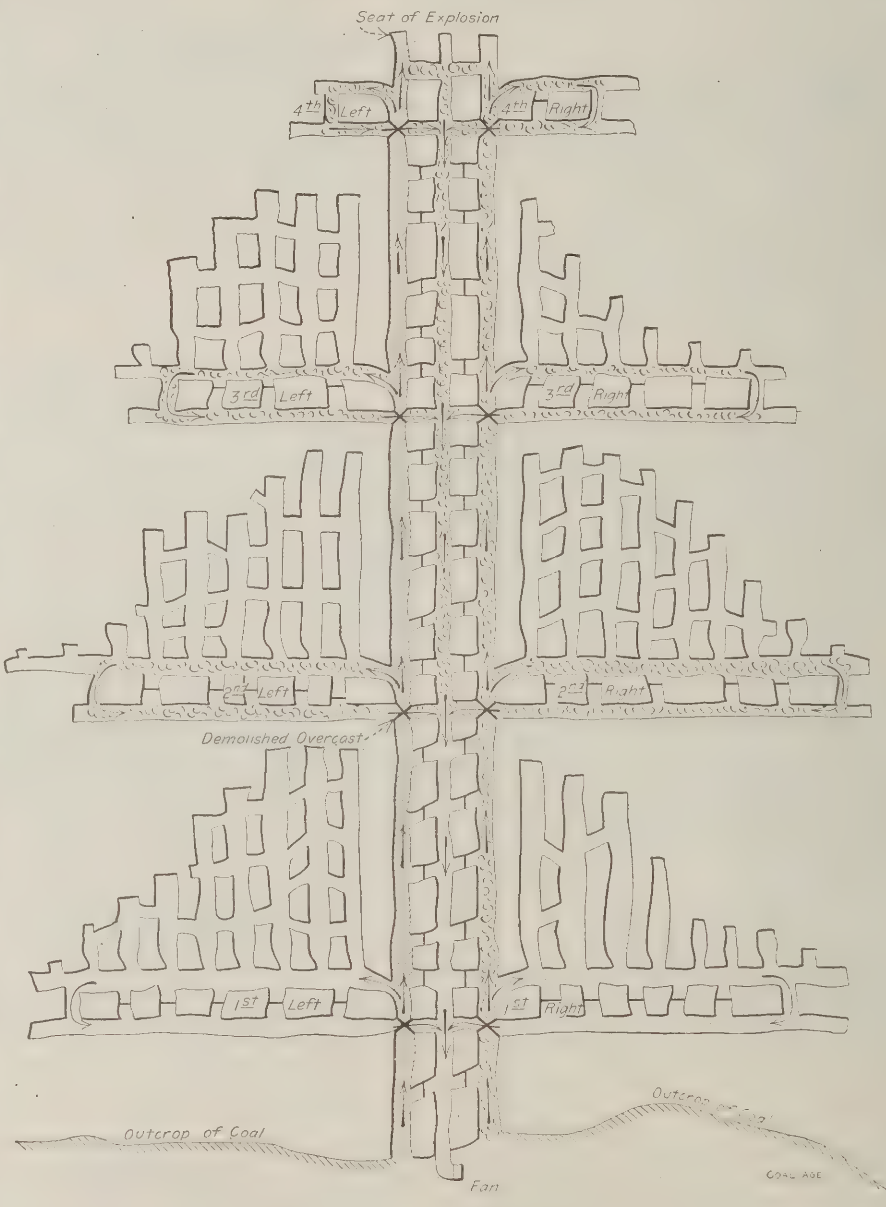
M. Taffanel, the French coal expert, makes the statement that explosions travel more frequently by intake airways than by returns and the Bureau of Mines asserts that the most usual direction of an explosion is toward the intake. I desire to point out later how apparent exceptions may possibly be regarded as mere exemplifications of the rule they appear to refute.

In the accompanying diagram of a mine in which the headings are enlarged, the arrows show the course of the air in circulation before the explosion. I have shown the seat of an explosion as the end of the left-hand face heading. The explosion is in a split of comparative unimportance so that the case is somewhat extreme, but the principle is not affected by that fact. The blast of exploding gases will pass out along the gallery from end to end, opposing the intake air and being prevented from entering the other airways. The causes, preventing the entrance to other airways, are two. At the mouths of some headings, the resistance of the stoppings is the excluding factor, at others the air is receeding from the blast, which for that reason shows only a moderate desire to enter. The blast regards the latter as returns and not intakes. In the sketch the airway affected by the blast is hatched with fine diagonal lines.

A Return May Appear to an Explosion as an Intake

What results if an overcast or a stopping blows out? Let us suppose an airbridge blows down at the 2d Left. Immediately the explosion meets the return air current at the overcast and regards it as an intake, for it is an approaching current. The whole of 2d Left is involved and that fact is indicated by the volumes of smoke curling therein in the illustration.

But as the overcast is completely demolished the explosion can travel toward the return airway. It does not *prefer* to do so, according to the best authorities, but it does so travel for a short distance. Here the distance is about 50 ft., certainly not enough to reduce appreciably the explosive force. Reaching the return, it cannot pass far to the right because the air is receeding, but on the left the return air is approaching and the explosion views it as an intake and runs back with increasing violence perhaps to the airways from the 3d and 4th Left and 3d and 4th Right. It has previously faced, of course, the return of 2d Right. The explosion spreads up the returns and then up the intake airways of all these headings because in all, the air current is contrary in every case to the blast's forward motion. In the illustration they are shown full of smoke. To make the illustration plain, the smoke has been confined to those headings where the blast opposes the air current, but as a matter of fact it will spread somewhat beyond those limits.



Suggested Course of an Explosion which Opposes Intake

And these considerations may well justify the belief that airways are sometimes affected by two or more explosions of contrary sign. Not only may explosions in embryo create more violent explosions at foci along their path, creating backward blasts over already traversed areas, but the explosion may travel around a circuit and arrive on a crossing of its former path and spread the débris anew so as to make the ascertainment of the initial focus well nigh impossible.

The principal value of strong stoppings is the fact that they preserve in-

violate the integrity of splits and so prevent the extension of an explosion. Had none of the stoppings blown out it is probable that the hypothetic explosion would have been less general and involved little more than the main-left gangway; it is certain the main-right gangway could not have been affected.

It is frequently thought that the value of a strong stopping is the probability of its preservation through the catastrophe to aid in rescue work.

But there are periods after an explosion when the safety of the men in the mine may be actually jeopardized by ventilation. It was the lack of ventilation which proved the one source of hope to some of the men entombed in the Cherry mine. Stagnant air was better to them than the air actually circulating. It must not be thought that if it were not for their help in reducing the area covered by an explosion, I would advocate weak stoppings, but I would point out that their main value is their power to fence around a blast so as to keep its devastation from involving the whole mine.

I hope you will publish this article despite the fact that it views the statement that the "air travels back on the intake" in the sense that it opposes the approaching air current. This is not the view, apparently, which is favored by the Bureau of Mines. George S. Rice leans at present to the opinion that the relative dampness of intake and return airways determines the direction of the explosive action. M. Taffanel gives no approval to any of the proposed determining factors. While not desiring to elaborate on the question, I favor the view that the direction of the air current is the main determinant of the direction of action of the explosion and that the chemical constituents of the air and the condition of the airways are but secondary considerations.

F. A. Boag.

Indianapolis, Ind.

What Constitutes a Good Air Current?

I note in the first issue, the reference of Francis N. Goff to the fact that "Advocates of unsplit air-currents are influenced too much by the brisk breezes of air, which are used in continuous current mines." The statement is justified, I think, by the experience of many mine managers.

I recall a superintendent of long experience who related with gusto, a story illustrative of the tendency to judge the strength and gage the value of an air current merely by its "feel," if I may so express it. Some of his men were loafing in a bar room and overheard the conversation of an Irish miner, who was busily discussing the superintendent's many demerits and incapabilities. Among other things he said:

"Oi had driv' a bit br—reast forninst a counter. The owld man come aroun' an towld me to make a bit ov a hole to pass the air through the pillar. I druv' the hole and the dr—raft was that bad it 'ud blow the cap aff yer head. The owld man kep' a comin' in, and tellin' me to 'Widen 'er out!' When Oi had it six fate wide and coal high, he towld me 'Alright,' but divil-a-bit of air was goin' through. You couldn't see it on your light at all, and he call himself a minin' boss."

Burns from Firedamp

Some time ago at No. 7 pit, Netherton colliery, Dudley, in England, an explosion occurred, in which five men received injuries. Two of these men died later, and at the customary inquiry into the cause of death, a new and possibly important medical theory was advanced by Doctor Paddom, senior house surgeon at the Guest hospital.

The names of the deceased miners were White and Ball, and the doctor said White would not, in all probability, have died from the effects of the burns if he had not had a serious illness before the accident, which rendered him a weakling. Ball, however, was a strong man, and in his case there was no scorching of the hair or charring of the flesh. There were simply large burns, due to great heat. Ball and White had sufficiently recovered from the burns to have some of their dressings removed, and they were considered to have passed the dangerous stage, so far as shock was concerned. In neither case was a fatal issue expected.

These were the circumstances, and Doctor Paddom gave it as his opinion, and also that of a medical man of far greater experience than himself, that there was something more than the severity of the burns to account for death.

Naturally, underground life might lower the powers of resistance of miners as a class, so that they have not the reserve fund of strength of men living in the open air; but the doctor was not justified in stating that this possibility might have operated in accelerating the death of Ball. In both cases there was evidence of the men being adversely affected by something more than their burns, and Doctor Paddom believed there was, at least in the nature of the explosion, something poisonous, which acted adversely to their chances of recovery. The doctor certainly did not expect a strong man to perish so long after the burns were inflicted, and while unable to say whether it was possible for the poisoning to have been caused by firedamp, he certainly thought a toxicologist should make investigations in Ball's case. The jury in returning the verdict added a rider, adopting the latter suggestion.

R. L. Lawrence.

Bristol, England.

[Our correspondent unfortunately neglected to give sufficient details to make the matter clear. There are a number of causes to which death under these conditions might be attributed: Gas poisoning, as suggested, the gas being carbon monoxide, resulting from combustion of the firedamp; second, shock which may be likened to heart failure, and third, the inhalation of flame. We would like to hear from any reader who may know of such a delayed death from a like accident. A statement of the causes to which death was attributed would be valuable.—Editor.]

Advocating Reduced Splitting

The effect of heated and moist air on human endurance is more marked than that of air containing 3 or 4 per cent. of carbon dioxide, even when produced by human exhalations and containing all their foul products. Leonard Hill has repeated the well known experiment by Doctor Haldane, of shutting men in an air-tight chamber. They experienced no distress so long as the heat and moisture were kept normal and the air moving.

I would like to call your attention to the bearing of this fact on the splitting of air, which was discussed in your first issue. A slow air-current in the mines always means excess warmth and a lack of due evaporation from the human body and is, therefore, to be condemned.

Hill even recommended, at the September meeting of the British Association, the use of stirring-up fans in submarine tunnel work, suggesting that it would agitate the inclosed air in a place where it was difficult to provide sufficient ventilation from outside owing to the extremely high pressures at which the work had to be conducted.

He stated, quoting the *Colliery Guardian*, "that the warm moist atmosphere brought much blood into the skin and depleted the viscera which perfected the blood and robbed the brain of ample flow." The human body demands air movement and it is also necessary to produce the proper admixture of gases in the mines; diffusion failing to produce that admixture adequately.

G. E. Algernon.

Chicago, Ill.

If all hoisting drums were surrounded by good stout railings many accidents might be prevented. If thin board partitions with canvas tops reaching to the rafters of the hoisting room are placed between the hoisting drum and the engineer, the particles of dust given off by the hoisting ropes cannot find a lodgment in the engineer's eyes and the danger of overwinding will be greatly reduced.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Inspection of Yellow Pine

I am receiving a large quantity of yellow-pine lumber for construction work and find the requisitions call for "merchantable inspection." Will you please tell me exactly what this means?

FOREMAN.

The 1905 rules of the North Carolina Pine Association, Inc., which are generally adopted, and in use, read as follows in regard to merchantable inspection. All sizes under 9 in. shall show some heart for the entire length on one side. All sizes 9 in. and over, shall show some heart for the entire length on two opposite sides. Wane may be allowed to cover one-eighth of the width of the piece, measured across the face of the wane, and extending one-fourth of the length of the piece on one corner, or its equivalent on two or more corners; provided, that not over 10 per cent. of the pieces of any one size shall show such wane.

"Heart" means wood from the heart of the tree; it contains the least amount of resin or sap in the pores and is stronger and more durable than sap wood. "Wane" means bark, or lack of wood for any reason, on the corners of the timber.

Energy Lost on Climbing Grade

If a trip, which will just run by gravity on a grade of 1.5 per cent. be landed at the head of a plane at 10 miles per hour on to an up-grade of 0.5 per cent., how far will the trip travel? R. F. B.

The resistance the trip would make on an even grade to motion would be $1\frac{1}{2}$ per cent. of its weight. On a 0.5 per cent. up-grade it would require a pull $= 1\frac{1}{2} + \frac{1}{2} = 2$ per cent. of its weight. Hence the force acting against the trip of which the weight is $W = W \times 0.02$. The energy this force would exert in a distance of s ft. would be $W \times 0.02 \times s$. The cars would lose this energy, continuing to run until it was all expended.

A speed of 10 miles an hour $= \frac{10 \times 5280}{60 \times 60} = \frac{44}{3}$ ft. per sec. The stored energy in the cars = ½ mass × velocity squared.

$$Mass = \frac{weight}{32.2} = \frac{W}{32.2}.$$

Therefore,

$$Stored\ energy = \frac{1}{2} \times \frac{W}{32.2} \times \left(\frac{44}{3}\right)^2 = W \times 3.34.$$

But the energy lost by the cars equals the stored energy when the trip is stalled. Hence,

$$W \times 0.02 \times s = 3.34\ W.$$

Canceling W,

$$s = \frac{3.34}{0.02} = 167\ ft.$$

The cars would run 167 ft. at which time all the stored energy would be expended.

An Inside Pumping Problem

I have a shaft mine with workings in two seams. At present the water from the upper seam runs to a large pump in the lower vein, but I want to send it from the upper vein directly to the surface. The lift will be 225 ft. and I find that a sump about 10x10x8 ft. fills in 12 min. What size pump will I require? R. P. K.

A sump 10x10x8 ft. holds 800 cu.ft., and since it fills in 12 min., there is an inflow of $\frac{800}{12} = 66\frac{2}{3}$ cu.ft. per min. For convenience and an added element of safety, it will be assumed that the inflow per minute is 75 cu.ft.

To determine the required size of pump let:

A = Area in sq.in. of water piston or plunger.
D = Diameter in inches of water piston or plunger.
A_1 = Area in sq.in. of steam piston.
D_1 = Diameter in inches of steam piston.
S = Piston speed in ft. per min.
P = Water pressure in lb. per sq.in.
P_1 = Steam pressure in pounds per sq.in.

The piston speed S, that is, the number of feet that the piston travels back and forth in a minute is usually taken to be 100 ft. per min., for medium-sized pumps. Using this value, the amount theoretically discharged by the pump piston each minute is.

$$100 \times \frac{A}{144}\ cu.ft.,$$

as a matter of fact, however, the actual discharge will usually be about ¾ of that amount because some water always slips past the piston and valves or otherwise leaks. Thus placing $\frac{3}{4} \times \frac{100\,A}{144}$, equal to 75 cu.ft. (the required amount), enables the value of A to be determined as follows:

$$\frac{3 \times 100 \times A}{4 \times 144} = 75,$$

$$A = 144\ sq.in.,$$

and the diameter

$$D = \sqrt{\frac{A}{0.7854}} = 13\tfrac{1}{2}\ in.$$

The hight of the column of water against which this pump has to work is 225 ft. + 10 ft. = 235 ft., 10 ft. being the probable hight of lift in the suction pipe should the sump run nearly dry.

The pressure resisting the motion of the pump piston is, therefore, theoretically $235 \times 0.433 = 101.75$ lb. per square inch where 0.433 lb. is the weight of a column of water 1 in. square and 1 ft. high. Friction in the pipes and at the valves, however, will probably increase this amount by 20 per cent. so that 125 lb. per sq.in. may reasonably be taken for the pressure.

The steam pressure carried at the boiler house will, lacking definite information, be assumed to be 100 lb. per sq.in. Probably 80 lb. per sq.in. is all that can be expected down at the pump and although small and medium-sized pumps do not as a rule use steam expansively, an average or mean effective pressure in the cylinder of 60 lb. per sq. in. is all that can safely be counted on. The total pressure against the steam piston has to balance the total pressure against the water piston, overcome the mechanical friction of the pump and also provide a surplus for starting up under load.

A fair allowance for the last two items is 20 per cent. of the whole. Then of the total pressure A_1P_1 exerted against the steam piston 8/10 A_1P_1 is the portion which can be relied on to balance the water column. Therefore, 8/10 $A_1P_1 = A\,P$ and substituting the values of P, P_1 and A

$$\frac{8 \times A_1 \times 60}{10} = 125 \times 144,$$

from which $A_1 = 375$ sq.in. and

$$D_1 = \sqrt{\frac{A_1}{0.7854}} = 22\ in.$$

These figures would indicate a simple double-acting pump having a 22-in. diameter steam cylinder and a 14-in. diameter water piston or plunger. The length of stroke would be determined by the design and proportions of the pump in accordance with manufacturing standards;

it would probably be between 14 and 18 in. but within certain limits the exact value is immaterial.

A pump of this type and size, 22x14x18 in., is, however, rather unwieldy and also likely to be wasteful of steam. A duplex pump, consisting of two smaller single pumps would undoubtedly give better results, in economy, regularity of flow, and facility in starting up.

To determine the size of such a pump, it is only necessary to find the diameter of two water and two steam pistons, the combined area of which will be equal, respectively, to the water and the steam pistons of the simple pump. Let d be the diameter of the water piston and d_1 of the steam pistons, then

$$d = \sqrt{\frac{A}{2} \div 0.7854} \text{ and } d_1 = \sqrt{\frac{A_1}{2} \div 0.7854}$$

or $d = 9\frac{1}{2}$ in. and $d_1 = 15\frac{1}{2}$ in. These figures indicate a duplex pump having 16 in. diam. steam cylinders and 10-in. diam. water pistons or plungers. As before, the exact value of the stroke is immaterial but would probably be about 12 inches.

The cost of briquetting in France, is placed at from 24 to 40c. per ton; in Germany, from 22 to 24c. per ton; in England, it is stated to be 24c. per ton. The Bureau of Mines gives the following estimate of the cost of manufacturing briquets in this country.

	Western States	Eastern States
Labor, including stacking...	$0.16	$0.20
Oil and grease..............	0.006	0.01
Sundry stores	0.01	0.01
Steam (fuel)	0.04	0.17
Depreciation	0.05	0.10
	$0.266	$0.49

Indications of Fracture

How can you tell where a bone is fractured?

FIRST-AID STUDENT.

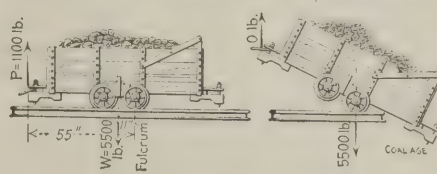
It is not always easy to tell that there is a fracture of a bone. But it is important to know, so that the fracture may not be followed by a cutting of the flesh while handling the patient. The indications are as follows: 1. The patient feels pain at that particular point and the point hurts when touched. But this is true of other forms of injury. 2. The broken ends of the bone may be felt. 3. The significant "crepitus" or rubbing of one part against the other may be heard. 4. The part may be altered in shape or shortened. 5. There may be unusual movement at the place where fracture occurs. The muscles acting on the bones under natural conditions are like ropes acting on a steel or wood structure. They cannot control the part of the body where a fracture has taken place, because the stiff part on which they act has collapsed. 6. Some inequality may be felt as you run your finger along the skin covering the broken bone. This will be more apparent soon after fracture, because swelling does not immediately arise to disguise it.

Rock Dumping with Gallows Dump

A car weighing 1500 lb. is loaded with 4000 lb. of rock, in a symmetrical manner, so that the vertical through the center of gravity falls midway between the axles when the car is level. The axles on the car are 22 in. apart between centers and the distance from the center line of the front axle to the point of attachment of the hook at the rear of the car is 4 ft. 7 in. It is purposed to tilt the car by pulling upward on the rear end of the draw bar by a chain maintained in a vertical line. What must be the pull on the tilting chain?

B. M. C.

The fulcrum or revolving center, on which the car is tilted, is the axle of the front wheels. The lifting force (P lb.) is situated 4 ft. 7 in. or 55 in. from that axle. The moment or leverage of $P = P \times 55$ expressed in inch-pounds.



UNLOADING A CAR OF ROCN

The weight of the car is 5500 ib., and its moment or leverage is $5500 \times$ half the distance between the axles, or 5500×11 in inch-pounds.

These leverages are equal when the car is about to move; that is, $P \times 55 = 5500 \times 11$, wherefore $P = 1100$ lb. It will be necessary for a lift of a little over 1100 lb. to be induced in the tilting chain in order that the car may be lifted.

The second figure illustrating this answer shows that by reason of the fulcrum, the load and point of attachment of the chain not being in one straight line, a little tilting of the car makes a great change in the lift required, even without any accompanying spilling of rock through the door or over it. The center of gravity of the car is high, and a tilt of 25 deg. in this case has made the load line, dropped from the center of gravity of the car, pass through the front axle; so that it no longer has any moment or leverage. It is not necessary under these conditions for the lift to have any moment and so P can be made zero. The car is balanced.

Example—In a similar case to the above, let the wheel base be 18 in. and the distance from the front axle to the rear hook 4 ft. 6 in. If the car weighs 5400 lb., what pull on the chain attached to the draw bar will upend the car?

Answer—900 pounds.

Grade on Rock Dump

We have been having trouble with our rock dump. We have read somewhere that the best grade for a road was 1.5 per cent. That is the grade we put in and now we find that occasionally the cars run without pushing toward the dump and are quite hard to push back; what grade should we have installed?

As the cars just run without pushing at 1.5 per cent., that shows that the resistance of the car to motion is 1.5 per cent. of its weight. Let us suppose your car weighs 1500 lb. and is loaded with 8000 lb. of rock. Then the resistance of the loaded car to motion, as it approaches the dump, which is the same as the frictional resistance on a level, is 9500×0.015 lb. $= 142.5$ lb. The gradient being x ft. per foot, the gravity impulse urging the car forward is $9500 \times x$. Therefore, the push demanded from the rock dumper must be the difference between the resistance of the car to motion and the gravity impulse helping it forward $= 142.5 - 9500 \times x$ *pounds*.

On returning the empty car the frictional resistance to motion $= 1500 \times 0.015 = 22.5$ lb. The resistance afforded by the car against its rising on the upgrade $= 1500 \times x$. The rock dumper has to combat both these resistances or give a push $= 22.5 + 1500\ x$.

Assuming that he can push in both directions with equal facility, the impulse will be the same in each direction.

That is,

$$22.5 + 1500\,x = 142.5 - 9500\,x$$
$$1500\,x + 9500\,x = 142.5 - 22.5$$
$$11{,}000\,x = 120$$
$$x = 0.010909$$

The grade should be 1.0909 per cent., say 1.1 per cent. instead of 1.5 per cent.

Heating Value of a Briquet

What advantage results from briquetting a coal that has a low heat value?

L. B. F.

The heating value of a briquet equals the heat units of the coal used plus the heat units contained in the binder. The heat value of organic binders is as great or greater than that of the coal used, hence they add slightly to the heating value of the briquet. Briquetting slack that is not especially high in heating value, permits a more complete combustion, and causes the coal to yield, weight for weight, an increased heating value. Anthracite slack is successfully briquetted in several localities.

If briquets crack in the process of manufacture the chances are that the right proportion of binder is not being used, the mixing is imperfect, or the compression is either insufficient or applied while the mixture is too wet.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Chairman Graham, of the House committee which is investigating the Alaska coal-land situation, will return to Washington within a few days and the investigating committee will be reconvened almost immediately. Hearings will be resumed at once and it is expected that Secretary Fisher and Director Holmes, of the Bureau of Mines, will be summoned before the organization. They will be asked to state what they learned during their visit to Alaska during the past summer. At the same time it is probable that Gifford Pinchot, who has also recently returned from an Alaskan visit, will appear before the committee.

Secretary Stimson, of the War Department, has issued a statement declaring his acceptance of the Taylor system of shop management and giving the results of an experimental use of the system at the Watertown arsenal. The Secretary's indorsement of the system is accompanied by what amounts to an agreement to put it into operation in other arsenals and at other Government works under the direction of the War Department. This has called forth strong protests from labor representatives and it is now stated that these representatives will resume their attack on the system before the House committee on labor, making it if anything more severe than heretofore. Some leading labor representatives have already expressed themselves; and at sessions which are to be held about the time of the reopening of Congress, others will present evidence. The committee is expected to report against the Taylor system. Thus a sharp issue may be joined between the administration and the labor interests.

Petition to Dissolve the Steel Trust

Attorney General Wickersham, Oct. 26, filed a petition for the dissolution of the so called steel trust. The petition describes the processes by which the United States Steel Corporation was built up, reviewing much of the ground covered in the Bureau of Corporations' report but giving comparatively little attention to the coal lands acquired during the early history of the concern. In discussing the later developments more attention is given to coal, and special stress is placed upon the fact that the present position of the corporation has been secured through the ownership or control of coal, coke, iron-ore and transportation properties.

In speaking of the Tennessee Coal and Iron deal the petition says that "by this purchase the corporation acquired 447,443 acres of mineral lands in Tennessee, Georgia and Alabama, containing approximately 400,000,000 tons of merchantable ore and 1,200,000,000 tons of coal, of which over one-third is coking coal. The Tennessee properties embraced 18 developed and active iron-ore mines and 23 coal mines, 16 blast furnaces, the ownership of several land companies holding extensive tracts of lands, and the Birmingham Southern Railroad Company, a terminal property of great value connecting the various mines and plants in the Birmingham district with all the diverging trunk lines. . . . ."

Later in speaking of the general position of the Steel Corporation, the petition says: "At its organization, it controlled the bulk of the best coking-coal lands in the Connellsville region and so acquired a great advantage over its competitors. In 1911, it made an important acquisition of coking-coal properties from the Pittsburg Coal Company. The control acquired of coking and other coal through the Tennessee company has added vastly to the strength of its position through absorption of raw material, thus locking it up and withdrawing it from the market, as an acquirement by its possible competitors."

Alabama

Birmingham—Announcement is made of the appointment of a protective committee, representing holders of the preferred stock of the Alabama Consolidated Coal and Iron Company who are dissatisfied with the proposed distribution of securities under the plan for the $30,000,000 merger with the Southern Iron and Steel Company.

California

San Francisco—The Pacific Coast Coal Company has concluded to retire from the California market, and has disposed of all its stock and transferred its interests to the Western Fuel Company.

The acquisition of the California business of the Pacific Coast Coal Company gives the Western Fuel Company control of all the existing bunker and lighterage facilities in the harbor of San Francisco.

Colorado

Denver—A temporary injunction has been granted by Federal Judge R. E. Lewis, prohibiting the Routt County Fuel Company from mining coal under 320 acres of land near Oak Creek. The injunction is also directed against the Union Land Company and the Continental Trust Company. Judge Lewis' decision is a victory for the Government in its campaign to prevent the alleged unlawful acquiring of valuable coal lands in Routt county.

Illinois

Mt. Vernon—Loren N. Wood has disposed of 7000 acres of Jefferson county coal lands to the Big Muddy Coal Company of New York. The purchase price has not been announced but is said to be more than $250,000.

Ottawa—A mortgage for the sum of $700,000 was filed in the recorder's office recently by the Chicago, Wilmington & Vermillion Coal Company. This large sum is for the purpose of purchasing 6000 acres of land in Franklin county, and developing it in the mining industry.

The St. Paul Coal Company has changed the location of its office from Chicago to Ottawa.

Indiana

Evansville—Two shot-firers were killed in an explosion resulting from a "windy" shot in the second level of the Ft. Branch Mining Company's shaft at Ft. Branch in the afternoon of Nov. 4, shortly after the miners had left the mine.

The United States rescue car from Evansville was soon on the ground, but because of the fall of timbers and débris that blocked the way the two bodies were not recovered until midnight.

Kansas

Pittsburg—The Hamilton Coal Company and the Girard Fuel Company have connected their main shafts and air shafts and are now working regularly.

Minden—The J. J. Pullen Coal Company, whose mine tipple was burned some time ago, will start to rebuild at once, having made a satisfactory settlement with the insurance company. As the mine is badly filled with water, it will in all probability not be ready for operation before Jan. 1.

Kentucky

Barbourville—The Martins Fork Company has bought a right of way from the main line of the Black Mountain & Wasioto railroad to the site of the mining

plant, near Harlan. Surveying on the spur line is now being done and the work of putting in the track will be started as soon as practicable.

Lexington—The Cambria Coal and Lumber Company filed articles of incorporation here recently. The business of the new company is to be the buying, leasing and operating of coal, coke, timber, oil and mineral lands. The capital stock is fixed at $500,000 and the principal office is to be in Lexington.

Missouri

St. Louis—It is reported that the Hawley-Erb syndicate has purchased the Novinger coalfields in Missouri. The same syndicate, it is said, will extend the Iowa Central to St. Louis, affording a through trunk line from Minneapolis and St. Paul to St. Louis, where connection will be made with the combination's Missouri, Kansas & Texas road to the gulf.

Maryville—More than 25,000 acres of land have been leased in Nodaway county in the last six weeks for coal- and oil-prospecting purposes. Work of drilling at various points in the county will begin within the next two weeks under the direction of R. W. Wallace, of St. Louis, who obtained the leases for an Eastern syndicate.

Ohio

Columbus—The Central Ohio Operators' association has filed complaint with the public service commission against the Baltimore & Ohio, Wheeling & Lake Erie and Pennsylvania railroads, charging that their rates on coal shipments are excessive, unjust and unreasonable. The association has a membership of operators in the Tuscarawas field.

Lore City—That portion of the Black Top mine of the Morris Coal Company which was on fire has been entirely sealed up and the burning portion thoroughly walled in. The mine has resumed operations.

Pennsylvania

Bituminous

Altoona—The Pennsylvania Coal and Coke Corporation, it is reported, will become the owners of the land and other properties of the old Pennsylvania Coal and Coke Company now held by a committee of the bondholders. The Pennsylvania Coal and Coke company controlled about 100,000 acres of coal land in Blair and adjoining counties. Of this acreage about 50,000 is being operated. Only the active land is included in the pending deals.

At a meeting to be held in Philadelphia, Nov. 10, it is understood the reorganization will be formally effected, an issue of stock authorized and a president and board of directors chosen.

The case of the Walnut Coal Company, a local corporation, against the Pennsylvania Railroad company for alleged discrimination in furnishing coal cars was recently brought to an end at Clearfield. The coal operators were awarded a verdict of $78,468, one of the largest awards ever given in a case of this character.

Uniontown—The H. C. Frick Coke company has fired 525 new coke ovens in the Uniontown and the Connellsville regions, making a total of 645 new ovens lighted last week. Placing in commission of these new ovens means the employment of about 1100 additional men.

Anthracite

Wilkes-Barre—Eight dredges have been at work for the past six months in the Susquehanna river near Bloomsburg and it is estimated that 10,000 tons of buckwheat and rice coal have been dug up. It is said that about 4000 tons more has been secured this year from the river near Danville.

G. B. Markle and Company have recently imported a number of negro laborers for work in driving a rock tunnel across the Highland basin. They are mostly expert rock men and their presence should not be construed as indicative of the intention to introduce negro labor in this field.

Pottsville—The tri-district convention of the anthracite mine workers, held here Oct. 31 to Nov. 3, formulated the demands which it desires to have made a part of the next agreement with the operators. The national president was empowered to order a suspension if these demands are not granted at the termination of the present agreement. The three most important of the 10 items are:—1. Recognition of the union. 2. An eight-hour day. 3. A 20 per cent. increase in pay.

Tennessee

Knoxville—The Bon Jellico Coal Company has been incorporated for $100,000. The purchase by this company of 1250 acres of virgin coal lands between Jellico and Williamsburg, Kentucky, is reported.

West Virginia

Wheeling—The sale of the coal lands and all properties of the Sleepy Mountain Anthracite Coal Company, of Morgan and Berkley counties, to Hay Walker, Jr., for the sum of $250,000, by special master in bankruptcy John C. Berry, was approved recently by Judge Dayton in the United States circuit court.

The Big Bluff Coal Company, of Huntington, has been incorporated to mine coal and manufacture coke and develop timber lands. The capital stock is $400,000.

Canada

Alberta—The strike of the coal miners of eastern British Columbia and Alberta, which has been in progress for nearly eight months, is at an end, and in the course of a few days it is expected that every one of the 25 mines in the district will be in operation, with 7500 men at work. The magnitude of the strike may be seen when it is stated that the mines represent an invested capital of $40,000,000, while the monthly payroll of the men totals in the neighborhood of a million dollars.

It is understood that an open shop is conceded to the operators and a nondiscrimination clause inserted in the agreement similar to the one now on file with the Department of Labor at Ottawa, also, that a uniform scale of wages shall apply, applicable to all mines in the association, said scale to be the scale of the Western Coal Operators' Association of the last agreement, with an increased percentage added.

Personals

M. S. Kemmerer, of Mauch Chunk, Penn., recently paid his annual visit to Kemmerer, Wyoming, where he has coal-mining interests. The town is named for him.

A. C. Leisenring, superintendent of the Upper Lehigh Coal Company, Upper Lehigh, Penn., has tendered his resignation to take effect Jan. 1. Mr. Leisenring has been connected with the anthracite industry for many years and now goes to assume management of a West Virginia Coal Company.

Announcements

The Book Department of the Engineering News Publishing Company, has been purchased by the McGraw-Hill Book Company, 239 West Thirtyninth street, New York. This adds to the list of the McGraw-Hill Book Company, a considerable number of important standard treatises, primarily in the field of civil engineering. The transfer of this business was made on November 6, 1911.

The U. S. Civil Service Commission announces an examination to be held Nov. 25, to secure eligibles from which to make certification to fill a vacancy in the position of assistant mechanical engineer in the Bureau of Mines, at a salary of from $2000 to $2750 a year. The duties of the person appointed to this position will be to assist and participate in the investigations of mechanical-engineering subjects connected with the mining industry, especially along lines relating to haulage and hoisting equipment. The examination will consist of the subjects mentioned below, weighted as indicated: General education and technical training, 40 points; professional and technical experience and fitness, 40 points; publications and official reports, or thesis, 20 points. Applicants must have reached their 25th, but not their 40th birthday. Examination form 304 and special form.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The optimistic views for an active winter trade are being slowly realized, particularly in sections where the recent cold wave was in evidence. The market, generally, is showing a better tone, with prices firm or advancing.

On the Atlantic coast, shortage of water transportation has resulted in light shipments, in most instances considerably below that of last year. Demand continues firm, especially for the better grades, with producers and railroads in good position to handle a large tonnage which it is thought will be greater this November than last. The slackening of lake shipments from the Pittsburg district has thrown an excess on the market with the result that prices are irregular, and mines only working from 55 to 65 per cent. capacity.

Lake shipments from Buffalo are a quarter of a million tons ahead of this time last year, but local trade is light. Reports from middle East points fluctuate almost directly with the weather, but are generally good, although prices are inclined to be irregular.

As a result of the cold snap in the middle West, there has been a noticeable strengthening of this market. Supplies are reported adequate, and the usual increase in prices is now effective in most sections, which is tending to retard buying.

In the Rocky Mountain States, trade continues active and there is a noticeable improvement in transportation facilities. On the Pacific coast, mild weather prevails and trade is therefore light, with slow rail shipments in the south due to the strike on the Harriman lines.

Boston, Mass.

The bituminous market is beginning to show signs of the advancing season. The colder weather has not been with us long enough to have any very marked effect on prices, but most of the larger shippers of standard Pocahontas and New River coals have advanced to $2.60, f.o.b. vessel at Hampton Roads.

There would soon be demand for Pennsylvania soft coals but for the fact that to get any advantage in freights their shippers would have to rely on Reading transportation, and the barges of that fleet are committed way ahead on anthracite requirements. The Somerset County coals are supposed to be on the basis of $1.20 at the mines now, instead of the $1.10 and $1.15 that obtained a week ago.

All-rail bituminous is practically unchanged. There is only a fair volume of coal moving, almost altogether on contract, and prices are still at low figures.

Reference to the following table will show the extent to which, on Oct. 1, the slow movement of transportation had affected the receipts of coal at the port of Boston, the figures being confined to domestic coal:

Anthracite receipts, September, 1911	125,436 tons
Anthracite receipts, September, 1910	153,516
Shortage, as against 1910	28,080
Anthracite receipts, 9 months ending September 30, 1911	1,358,925
Anthracite receipts, 9 months ending September 30, 1910	1,273,344
Excess, over same period, 1910	85,581
Bituminous receipts, September, 1911	316,039
Bituminous receipts, September, 1910	362,802
Shortage, as against 1910	46,763
Bituminous receipts, 9 months ending September 30, 1911	3,024,578
Bituminous receipts, same period, 1910	2,982,785
Excess, over 1910	41,793

In other words, while the total tonnage, in both anthracite and bituminous, in the nine months from Jan. 1, was considerably in excess of the receipts for the same months in 1910, yet the tonnage for the month of September was materially behind that of last year. October will show tonnages still further in arrears.

New York

Although the standing tonnage at the New York piers is somewhat above normal, the demand on contract is so good that standard-grade steam coals are moving from the piers with fairly prompt despatch and there is no unwieldy accumulation of these grades at tidewater. Inferior steam coals, however, still continue to be a drug on the market and shippers of this class of coal ought to realize that it is very poor policy to overship this market under present conditions.

There has been a little spot business in the market this week but the amount of the tonnage has not been large. The car supply in the regions shipping this market is reported satisfactory and mines have accordingly been in a position to work full time when required, although two church holidays last week had a tendency to decrease production. Railroad movement at New York tidewater is prompt, which is an aid to those producers who have heavily contracted, in the taking care of their obligations.

Demurrage coals, which are in practically every instance low-grade steam coals, are being offered at sacrifice prices. Quotations on other steam coals range about as previously reported, $2.35, f.o.b. for West Virginias (80c. at the mines); $2.35@2.45 for ordinary Pennsylvanias; $2.25@2.65 for good Pennsylvanias; and better-grade Pennsylvanias, $2.65@2.75.

Philadelphia

Temperature has not been a very potent factor in the coal trade during the last week, or even during the past month. The demand seemed to be altogether spontaneous, as if the householders had put off purchasing until the last minute, and then all wanted their coal at once. October was inaugurated with an unusual activity in the coal trade, which simmered down to a fairly active trade during the closing days.

The wholesale market has its work cut out for this month, if it is to show an advance over last year's business. November has started in auspiciously, as the reports already show very substantial increases over last year, and any kind of weather should enhance this, but the tonnage last year for this period was very good, and it will take some good cold weather to enable the market to keep up to the record already set. Line trade is reported fairly active, while the tidewater business is very good, orders being in excess of the ability of the companies to supply. Prices at tidewater: Broken, $4.50; egg and stove, $4.75; chestnut, $5. Line prices $3.75 for egg and stove, chestnut, $4; pea, $2, at the mines.

Pittsburg

Bituminous—Very little more coal will be taken up the Lakes this month, and none at all next month, the Lake insurance expiring Dec. 1. Besides the congestion at upper Lake points acting as a brake on the movement, Lake tonnage is difficult to secure as there is practically no possibility of vessels obtaining return cargoes of ore, and in many cases Lake vessels are being used for coal storage during the winter, being already loaded for their first trip in the spring.

Prices have become somewhat more irregular in consequence, and slack, which normally firms up at this juncture on account of greatly decreased production, is

no stronger than it was. We repeat former quotations, although they are probably being shaded somewhat more frequently than before: Nut, \$1@1.05; mine-run, \$1.05@1.10; ¾-in., \$1.15@1.20; 1¼-in., \$1.25@1.30; slack, 40@50c., per ton at mine, Pittsburg district.

Connellsville Coke—The market is devoid of important developments. Demand for spot coke, both furnace and foundry, is very light, but prices being already down to bed rock, the majority of merchant producers have not suffered. Consumption is unchanged, but is fully covered by existing contracts. More than one-half the total production of the Connellsville and Lower Connellsville region is by interests which are themselves consumers. Of the remainder, or merchant production, more than one-half is covered by contracts which will extend into next year, a few being twelve-month contracts running to July 1, 1912, but the major part are longer-term contracts either at a fixed price or at a ratio to the average prevailing price of pig iron. Thus while some important contracts will have to be made for the half year or year the tonnage involved will be a relatively small percentage of the total output. No serious negotiations have yet been undertaken and as there is an ample surplus of capacity, business may not be closed for 30 or 60 days yet. We continue to quote: Prompt furnace, \$1.50@1.55; contract furnace (nominal), \$1.65@1.75; prompt foundry, \$1.80@1.90; contract foundry, \$2@2.25.

The *Courier* reports production in the Connellsville and Lower Connellsville region in the week ending Oct. 28 at 320,301 tons, an increase of 10,000 tons, and shipments at 3947 cars to Pittsburg, 5028 cars to points west and 952 cars to points east, a total of 9927 cars, an increase of 164 cars.

Buffalo, N. Y.

There is still a slight increase in the movement of soft coal, and conditions are satisfactory with the exception of prices, which do not promise to improve much, for the operators are so situated and so minded that they will increase the output in direct proportion as the demand increases. So long as this condition exists there can be no rise in prices, unless something unusual happens to curtail the production.

There is some falling off in the trade just now because of election, but the general quiet state of business is accountable for most of the change in that direction.

Soft-coal prices are unchanged at \$2.50 for Pittsburg three-quarter, \$2.40 for mine-run and \$2 for slack, with Allegheny Valley coal from 15 to 25c. lower. Slack is still quite unsteady and needs cold weather to give it proper firmness. The coke trade is still dull, with prices on the basis of \$4 for Connellsville foundry and \$3.50 for stock coke. There is quite an amount of smithing coal sold here on the basis of \$4 for Georges Creek Cumberland, but dealers find that most consumers buy Cambria county smithing or washed slack, which sells all the way down to 50c. less.

Cleveland, Ohio

The Lake coal trade, with the exception of three or four concerns who are handling their own coal direct, is practically closed for the season. Considerable coal still remains on track and is now being loaded as quickly as possible in boats for storage during the winter months.

The domestic trade at this season should be much better than it is, but owing to the very mild weather during the month of October and up to the present date, the domestic demand has been very small.

There does not seem to be any improvement in the domestic trade or steam trade in the past week, excepting slack, which has advanced from 10 to 15c. The following are current prices per short ton here:

Ohio No. 8	
Mine-run	\$0.95@1.00
¾-in.	1.05@1.10
1¼-in.	1.15@1.25
Slack	0.50@0.60
Middle District:	
Mine-run	\$1.00@1.10
¾-in.	1.20@1.30
1¼-in.	1.45@1.60
Youghiogheny:	
Mine-run	\$1.10@1.20
¾-in.	1.30@1.35
1¼-in.	1.40@1.50
Pocahontas:	
Mine-run	\$1.00@1.10
Lump	2.10@2.25

Columbus, Ohio

One of the best phases of the business is the demand for immediate shipment. For a time domestic business was fairly brisk in orders for future shipment but the cold spell caused a rush of orders for immediate delivery. Prices are ruling strong in every grade and there is no complaint of price cutting in any section. The general tone of the market is better and the prospects for the future believed to be satisfactory.

The lake trade in all districts of Ohio continues active in every respect and the Toledo docks of the Hocking Valley railroad have been busy recently, loading boats for the Northwest. During the week ending November 4, 56,000 tons were handled by the Toledo docks while the previous week the record was 71,000 tons. Since the opening of navigation the tonnage handled at the Toledo docks has been 2,225,000.

Production in various Ohio fields has been slightly above that of the past few weeks. In the domestic fields such as Jackson and Pomeroy Bend the output is about 85 per cent. of the average and in the Hocking valley the output is about 80 per cent. In eastern Ohio the output ranges between 70 and 80 per cent. of the average. In other fields there is a slight increase in the production due to the better conditions of the trade.

The retail trade is on the increase. The cold wave has caused a rush of orders and dealers are busy taking care of deliveries. There is a good demand for the fancy grades of coal, particularly the splints and especially prepared varieties. Stocks in the hands of the dealers have been quite short and this means a rush of orders to the operator and wholesaler. Farmers are also buying much better since they have their work in hand better. Retail prices are strong but have not yet reached the winter level.

The fine coal market is slightly improved and prices show more firmness. The supply is still large and there are many cars in storage. Nut, pea and slack are selling at between 40 and 50c. and coarse slack between 35 and 40c.

Prevailing prices are as follows:

Hocking Valley:	
Domestic lump	\$1.50
¾-in.	1.35
Mine-run	1.10
Eastern Ohio:	
Domestic lump	1.65
Nut	1.15
Nut, pea and slack	0.45
Coarse slack	0.40

Cincinnati, Ohio

This is distinctly a weather market, with demand slightly better, as to both steam and domestic fuel, although, of course, the former is dependent upon general industrial conditions, which have not changed sufficiently—either for better or worse—to make a noticeable difference in the steam demand. The weather has been favorable for domestic demand. The temperature was considerably below freezing several nights last week in this immediate market and north of here the weather has been more severe.

Coal men never rejoice at anyone's misfortune, but they are human—at least the Cincinnati ones are. Consequently when, Friday of last week—all day and evening—a break in the gas main in West Virginia practically cut off the city's entire supply of gas there were lots of "I told you so" from coal men when they had time to say it between filling rush orders for fuel demanded by former customers who had been induced to substitute gas. Several business concerns in the city were forced to practically shut down and in one city institution at least—the city hospital—there was decided inconvenience.

Charleston, W. Va.

With the lake shipments practically at an end for this season, shipments are not now as heavy as they were. Some coal is still going to the lakes, but the re-

duction in the amount is not balanced by the increase for winter consumption, and, therefore, it is contended that at present there is a decrease rather than an increase in shipments. There has, however, been an increase in shipments other than to lake points.

No change in prices is reported. Instances are cited where a slight increase has been secured, but others are also noted where new contracts have been closed for less than the old ones. As a general rule coal men are not inclined to change their views heretofore expressed, that the future is none too bright for their interests and that little increase in the price of coal can be expected for another year or year and one-half.

Indianapolis

The retail coal trade which now occupies the center of the stage as regards distribution of domestic coal has been greatly stimulated by colder weather over a wide area of country. In fact, reports regarding this branch of the coal business show a healthier tone than they have for many months.

The usual annual increase in the price of coal became effective in Indiana, Nov. 1. Consumers are now paying from 25 to 50c. a ton more than previous to that date. The local dealers say it is due to the advance in wholesale prices. No advance, however, has been made on Indiana coal at the mines. Present prices are said to be the same as at this time last year and the advance on eastern coal was wholly expected.

Chicago

Weather, the car situation and quality of coal are the three dominant factors in the Chicago coal market at present. The recent drop in temperature brought brisk buying with the result that the wholesale and retail markets have been active. There has been a noticeable strengthening in the country districts, this being due to a limiting of the car supply for movements westward. The increase in country prices has ranged close to 25c. a ton.

Lump coal is not moving very rapidly in Chicago, and while some concerns are making an effort to maintain $1.75, others are offering $1.65, with differentials of 10c. below that figure on egg and nut. The result has been an increased demand for egg and nut and a weakening in the price on lump.

Prices direct from the mines in net tons to retail dealers and steam users on spot shipments are as follows:

	Chicago	F.o.b. Mines
Sullivan County:		
Domestic lump....	$2.35@2.45	$1.50@1.60
Egg..............	2.25	1.40
Steam lump......	2.10	1.25
Screenings........	1.22@1.32	0.35@0.45
Springfield:		
Domestic lump....	$2.22@2.47	$1.40@1.65
Steam lump......	1.92@2.02	1.10@1.20
Mine-run.........	1.82@1.87	1.00@1.05
Screenings........	1.22@1.32	0.40@0.50
Clinton:		
Domestic lump....	$2.17@2.37	$1.40@1.60
Steam lump......	2.00@2.20	1.25@1.45
Mine-run.........	1.82@2.02	1.05@1.25
Screenings........	1.27@1.37	0.50@0.60
Pocahontas and New River:		
Mine-run.........	$3.00@3.10	$0.95@1.05
Lump and egg....	4.05@4.30	2.00@2.25
Coke:		
Connellsville......	$4.50@4.65	
Wise county......	4.50@4.65	
Byproduct, egg and stove..........	4.95	
Byproduct, nut....	4.55@4.65	
Gas house........	4.85	

Minneapolis—St. Paul

The expected turn for the better in the coal trade has happened, and the wintry blasts, with a slight fall of snow, should have credit for the change. After all is said, no one other influence stimulates the coal trade as generally as a continuous spell of cold weather.

The wholesale trade is showing a marked improvement. The buying has been slower than usual by the country dealer. They were stocked up as strong as they cared to be until the consumer showed some inclination to buy. The advance of winter has brought this about and now the dealer is reordering to fill up bins being depleted. What is known as the Line House trade have been liberal buyers within the past 10 days. These are the large retail-lumber companies and the elevator companies who are located with principal offices mainly in Minneapolis conducting a line of yards throughout the Northwestern States.

The steam market continues to be the discouraging feature of the trade. No change is looked for this year. There seems to be a rivalry between two or three dock companies and it looks like a fight for supremacy in this market. The larger companies are taking the lead in setting the price on steam trade and the jobber is practically out of it.

St. Louis, Mo.

Country demand for all kinds of coal is especially good and a large tonnage is moving through St. Louis to the Northern and Western market. The prevailing prices are:

STANDARD	
6-in. lump	$1.10@1.20
3-in. lump	1.10@1.15
2-in. lump	1.05@1.10

Mount Olive and Staunton District coals are still holding at about $1.25@1.35 for domestic sizes. There is a good demand for the higher-grade coals from the inner district at from $1.90@2.25. The above coals take a rate of 52c. to St. Louis.

FRANKLIN COUNTY	
6-in. lump	$1.60@1.75
3x6 egg	1.55@1.65
No. 1 nut......................	1.50@1.60
No. 2 nut......................	1.20@1.30
WILLIAMSON COUNTY	
6-in. lump	$1.50@1.60
3x6 egg	1.45@1.55
No. 1 nut......................	1.15@1.20
No. 2 nut......................	1.00@1.10
No. 3 nut......................	0.90
Mine-run	1.05
½-in. screenings	0.45

The above coals take a 67c. rate to St. Louis.

There is a good movement of Big Muddy coal from the Murphysboro field and some coal moving in from the Harrisburg district.

During the past week there has been a heavier tonnage of Springfield coal moving in than at any previous time this season. There has been a decided scarcity of anthracite chestnut, and it is very hard to get. The other sizes are moving freely, and a steady tonnage is coming forward at the regular circular.

Salt Lake City, Utah

Lack of equipment is the only thing which seems necessary to make this a banner year for the Utah mines. The demand is good, labor conditions satisfactory and weather so far ideal.

Generally speaking the mines have been doing better with their productions the past week. Colder weather has increased the demand, however, and they are still far behind with orders.

Special efforts are evidently being made by the Denver & Rio Grande in transporting coal and the result has been a very marked improvement in the service.

Prices on wholesale coal were boosted by Wyoming and Utah mines about the first of the month. Lump is now $3; nut, $2.50; run-of-mine, $1.85, and slack, $1, f.o.b. cars at Wyoming mines. Slightly lower at Utah mines.

Retail trade is splendid in Salt Lake and some of the smaller dealers who had not much coal stored are hard pressed for coal to fill orders.

Retail prices are still the same, that is, $5.75 for lump; nut, $5.50; slack, $3.25 delivered.

Portland, Ore.

The coal market is dull locally, due to the fact that it is between seasons, the weather continuing mild. The summer storage supplies were removed Oct. 1, and the next change in values here will be an advance. How soon this will come depends altogether upon weather conditions. The fall weather has been ideal and hence few coal purchases have been made, those who buy for the month having no occasion to enter the market yet.

Little coal is coming in from Australia this season, and the railroad strike does not appear to have caused the Harriman lines any serious inconvenience in this section as yet. The country throughout appears prosperous, although some complaint is heard of dull business.

Following are the prices asked here per ton, including cost of delivery to points within the city proper:

Japanese	$7.50	
Washington lignite...	$7.00@ 7.50	
Australian	10.00@10.50	
Rock Springs, Wyo...	10.00@10.50	nut $9.50
Diamond, Wyo.......	10.00	
Carbon Hill, Wash., lump	10.50	
Carbon Hill, steam...	7.50	
Newcastle, Wash.....	7.00	
Beaver Hill, Ore.....	9.00@ 9.25	
Blacksmith coal	17.00

COAL AGE

Vol. 1 NEW YORK, NOVEMBER 18, 1911 No. 6

A young engineer, fresh from college, reported to the manager of a small coal company for his first-day's work. The task assigned was to map a virgin-coal acreage, paying particular attention to surveying and plotting the outcrop of the seam.

This youthful graduate hastened to consult his textbook, and found that in running a coal crop, he should—first, "pay close attention to the change in color of the vegetation overlying the outcrop"; second, "observe that the floor of the seam would be marked by iron and sulphur springs along the route." Thus enlightened, the task appeared easy and work commenced.

Suffice it to say—the change in the color of the vegetation was not discernible to human eye, and to judge by the springs on the hillside, the contour following the coal closely resembled a cross-section through the foothills of the Rockies. Not a bit discouraged, although isolated from helpful advice, this engineer (pardon me for calling him such; 'tis an evil custom fostered by our great colleges) totaled all his knowledge on the subject, seasoned the whole with practical common sense, and proceeded to solve the problem in his own way.

Trenches were dug at intervals and the coal partly exposed. Contours were taken above and below the seam and the outcrop satisfactorily plotted.

The lesson was a valuable one and taught our young friend that his textbooks might often prove a help, but not a panacea for all mental ills. He began to realize that his education was just beginning, rather than having been concluded; that theory is essential, but experience is hands and feet to every endeavor.

His next move was to resign as engineer for the company, and accept a job at half the pay, as backsight on the surveying corps of a larger concern in an older field. Here he associated with men wiser and more experienced than himself; the inspiration and knowledge gained were many times worth the price paid.

Lesson number two was now learned, and was the reverse of his first instruction. It had to do with experience minus theory. The teachers of this lesson were a few of the doughty sons of toil, who, because they lacked an early mental training, tried to induce the belief that education is purely physical, and that wisdom is never gained from books.

These men showed how to light a gas feeder and then beat it out with their coats; they were apt instructors in methods for opening safety lamps at the face when a naked flame was wanted to light a pipe, and the best part of their time, when not actually drilling or loading, was spent in condemning new laws or devising means to evade company rules that had been designed for their own safety.

And it wasn't the miner alone who taught him lesson number two; there were foremen and superintendents who believed it a crime to spend money grading roads when they might be driven water-level; splitting the air was a perversion, and a Jacob's-staff in the hands of a foreman, so they believed, was sufficient means for setting room and entry centers.

Don't imagine that our embryo engineer failed to discern the fallacy in their reasoning, nor that he neglected to profit by the error of their ways. It was plain to him there was little to choose between the theorist and the practicalist. Both were equally a menace.

The result of these observations led him to conclude that the combination to be sought embraces both book-learning and the wisdom born of practical effort, and that such an education develops a man to his highest capacity, increases his individual power of production and makes him a good companion for himself and others.

The sooner we mix brains and work, the greater will be the advance in coal mining. No matter whether we have come down from the college or up from the mines, the one essential to a prosperous issue is hard-headed common sense. The fellow who tries to get along only with his head or only with his hands, will travel about as fast as an automobile with the engine running and the clutch thrown out.

Anthracite and Bituminous Mining

By Eli T. Conner*

The central Pennsylvania bituminous field, while advantageously located near tidewater, possesses only thin seams of coal and mining here is commercially precarious. Coal-cutting machines and electric haulage are the most potent factors in securing economy. The fourth of a series of articles by Mr. Conner.

Bituminous coal is found in so many States of the Union, under such widely varying physical and geological conditions, that it will be impossible in the space at my command, to discuss more than one or two typical regions. Therefore, in the main, this article will be devoted to those coalfields in which I have had personal experience both in the development and operation of coal mines, and the manufacture of coke.

Pennsylvania, the leading State in the production of bituminous coal since the beginning of the industry, has naturally been foremost in the development of mining methods and in the education of all classes of coal-mining employees. In the pursuit of my profession, in many other States, as far west as the Pacific coast, and in the Rocky mountains of British Columbia and Alberta, it has been my good fortune to meet many foremen, engineers and managers whose early experience was acquired in the Keystone State. The cordial treatment I have received from these men has, perhaps, been due partly to a feeling of sentiment, as well as to business reasons, and remarks have frequently been made expressing pleasure at meeting an engineer from "back home."

This State, therefore, not only deserves credit for its great contribution of natural products to the economic development of the country, but still greater credit for its well trained, resourceful and energetic sons who are helping in the development of newer fields.

Collieries Nos. 3, 5, 6 and 8, Ehrenfeld, Cambria County, Penn.

The Pittsburg Bed

As is well known, the remarkable growth at Pittsburg of industries of all kinds, but particularly those of steel and iron, has been due almost entirely to the wonderful deposit of high-grade coal, known as the Pittsburg bed, which is conceded to be in every respect the most remarkable seam of bituminous coal found anywhere in the United States. The physical characteristics of this bed place it in a class by itself, in the matter of economical production. I shall not go into a description of development and mining methods in this bed, because I think it can, as a whole, be described better by men of wider experience in its operation, than has been my own. But in the interest of conservation, I desire to call attention to the most important feature of the mining practice in this region, as quite largely developed in the Connellsville basin.

Here, the original layout and projection of a mine is made with the view of ultimately securing the complete recovery of *all* the coal. Of course, this is the prime object in all coalfields, but the system of pillar distribution and reclamation of pillar coal, as practiced in the Connellsville field, results in an exceptionally high yield of the mineral in the ground. This is largely due to favorable natural conditions as to thickness and quality of coal, good bottom and the character of the overlying strata, which is of such a nature that generally, when pillars are systematically withdrawn the roof breaks properly, with a minimum of pressure on the remaining pillars. I mention these facts particularly because I think the methods that have been developed in the Connellsville field for the reclamation of pillar coal, constitute in the matter of yield almost as high a standard as does Connellsville coke in the market.

What is known as the Central Pennsylvania bituminous coalfield includes part of Center, Clearfield, Cambria, Blair, Somerset, Indiana and Jefferson counties. This field is the nearest of any in the Appalachian Range to tidewater, at New

*Consulting engineer, Real Estate Trust building, Philadelphia, Penn.

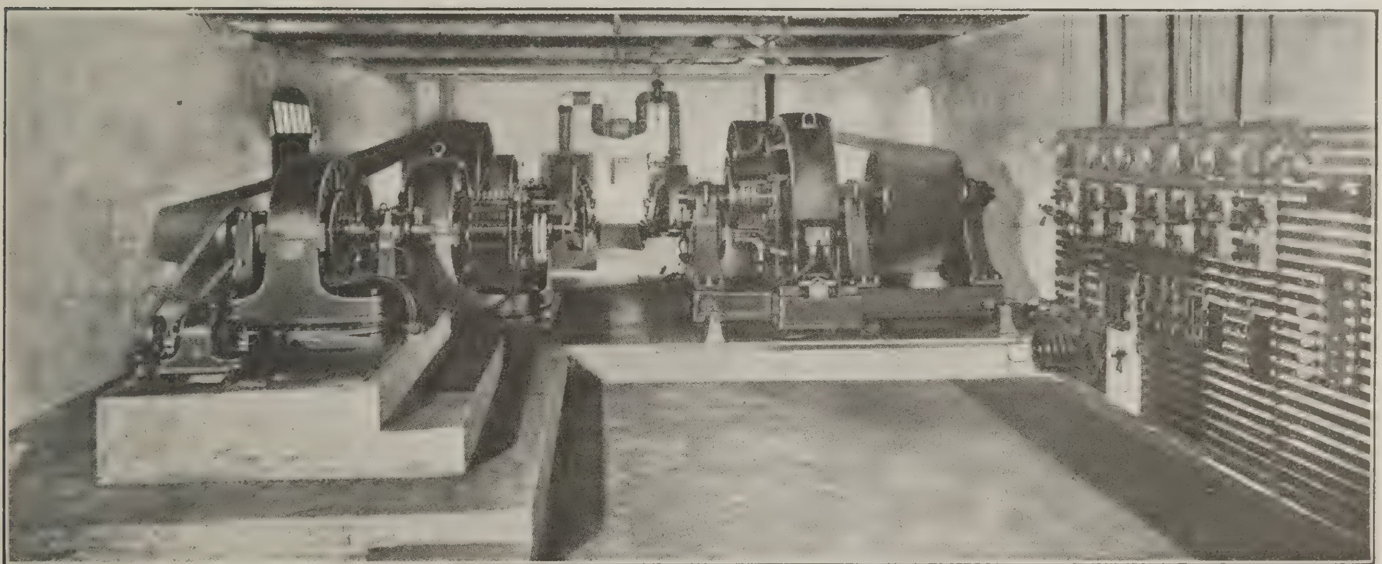
York, the average distance being 250 miles, which gives it a natural advantage over the other regions that are more favored than this as to geologic and structural conditions. The earlier developments in this region were made in the justly celebrated Moshannon or D bed, in Center and Clearfield counties. The quality of this coal is so good that very shortly after its first exploitation, it established a reputation in the market, which it continues to enjoy. However, most of this high-grade coal has been won and, comparatively speaking, there is but little of it now being produced.

Mining in Central Pennsylvania

The mining in central Pennsylvania is at present almost wholly in beds B, C Prime, D and E. The average thickness of each of these four seams of coal will not exceed 3 ft. 8 in. Notwithstanding this fact, central Pennsylvania is producing in the neighborhood of 45,000,000 tons of coal per year. In order to overcome the great handicap of such thin seams as are found in this region, the operators have been compelled to exercise much more ingenuity that is necessary in competing regions where the beds of coal are thicker. The success of these efforts upon the part of central Pennsylvinia operators, is deserving of great credit.

As is well known, the coal measures in this region are comparatively flat; pitches rarely exceed 15 per cent., and in most cases are much less. The earlier developments were naturally by drift from the outcrop, and were made by individual operators having comparatively small capital. With the gradual exhaustion of the above-water-level coal, developments have been made on a much larger scale by slopes and shafts, so that at the present time, there are in this region many plants of large capacity, constructed on the most modern lines.

Entries are usually driven in pairs, but where the ultimate distance to the boundary exceeds one mile, it has been found necessary to drive three and sometimes four parallel entries in order to provide sufficient area for ventilating purposes, without handling an excessive quantity of rock. In all entry work, in these thin seams, it is necessary to remove a sufficient amount of either top or bottom rock, the choice depending upon their relative character and hardness, to provide a clearance of about 5 ft. 6 in. over the rail. Entries are usually driven 12 ft. wide in the clear, and the best practice is to transport the rock which is removed, to spoil banks on the surface, although it is the custom in some mines to widen the entry in the coal sufficiently to make room for storing the rock removed from the roadway. This latter method I do not consider good practice, as it weakens the entry support and frequently results in falls of roof.



Electric Power Station, Pennsylvania Coal and Coke Company, No. 10 Mine, Gallitzin, Cambria County, Penn.

The room-and-pillar method of mining has been adopted almost universally. There is but one instance within my knowledge of consistent effort to introduce the longwall method, and that was at Vintondale, in Cambria county, under the supervision of C. R. Claghorn. This work was done in connection with a conveyer, designed and patented by Mr. Claghorn, which was used for transporting the coal across the longwall face, and discharging it into cars on the butt entries. I was privileged to inspect a mine where this system was in use, and was favorably impressed with its efficacy, particularly with relation to the winning of all the coal on first mining. The details of the system have been described in articles published by Mr. Claghorn and others, so that they need not be discussed here, and are only mentioned to bring out the point which, in my opinion, has been neglected too long by American engineers, namely, the advantages to be gained by the general introduction of longwall mining in beds of coal under 4½ ft. in thickness.

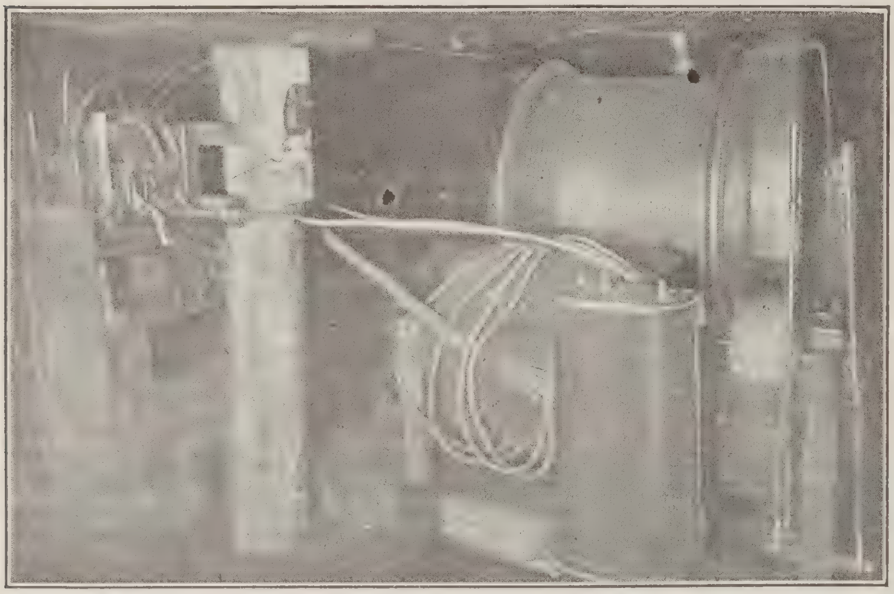
Removal of Rock

While there are many mines where it is customary to remove some roof or bottom rock in the rooms to make hight for cars and mules, this is not the general practice. It is customary to remove top or bottom rock merely at the entrance to the rooms, and thereafter the only excavation made is in the coal seam proper. The mine cars are usually constructed with a capacity of from 1¼ to 2 tons, and low enough to be handled in openings not exceeding 3½ ft. off the rails. All mine cars are equipped with brakes. The cars are delivered to the room neck, by motor or mule team, and pushed by the miner and his helper both ways in the room. The compensation for this labor of pushing cars is included in the mining price. This practice of pushing cars is not universal, since it cannot be carried on successfully where the grades exceed 3 or 4 per cent. In such cases, it may be necessary to brush a small quantity of roof rock from over the roadway in order to admit small mules, say 50 to 52 in. in hight.

In recent years, small electric locomotives have been put on the market, which are equipped with cable reels and are doing successful work in the matter of gathering from rooms. These locomotives are usually of about four tons weight, and low enough to be used in 3½-ft. openings.

I submit two statements showing in detail the transportation cost at a small bituminous mine where the seam is 4 ft.

thick, and where one side of the mine is operated by electric locomotives and the other side by animal power, from which it will be noted that over 6c. per ton economy is effected by the use of electric locomotives. This does not represent all the economy in this particular instance, since in a number of the rooms where mules are used there is some cost for removal of roof or floor, to make hight, but in compiling these statements, this was not considered.



Electric Hoist Underground at Colliery No. 3, Ehrenfeld

Motors vs Mules

Tonnage 4095.10, gathered by mules and hauled from sidetrack by electric motors.

Electric Power Station at Ehrenfeld, Penn.

The above comparison is given because the conditions under which the gathering locomotive and the mules worked, were almost identical, although the grades in rooms served by the gathering locomotive were somewhat heavier (12 per cent.) than on the other side of the mine, where mules were used.

From this and other experiences, I am quite satisfied that the use of gathering locomotives when properly installed, should result in an economy of not less than 4c. per ton, as compared with ordinary methods of gathering from rooms with mules.

It might be well to state that in the case just mentioned, particular attention was paid to the design and installation of tracks and switches. The track in the entry where the locomotive was used, was of 25-lb. steel rails, properly spliced at joints with fish plates. The switches and frogs were also of 25-lb. rail and designed the same in every way as the switches and frogs on standard-gage railroads. The minimum curve permitted was of 30 ft. radius. The tracks in rooms were laid with 16-lb. steel rail, fish-plated.

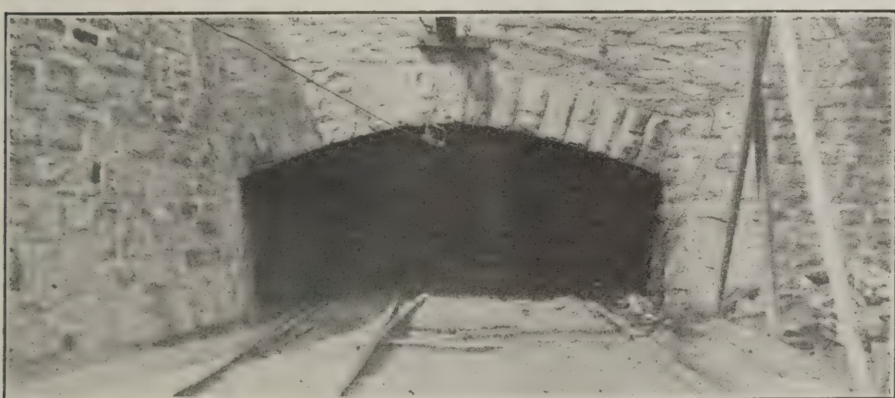
Before leaving the subject of transportation, it should be said that most of the important mines in central Pennsylvania have adopted electric transportation on all their main roads and find it profitable to go to considerable expense to grade and aline the tracks properly. One case in particular with which I am familiar, is the main entry in the B or Miller seam, at No. 3 mine, of the Pennsylvania Coal and Coke Company, at Ehrenfeld. Two tracks of 56-lb. rails were laid in this entry for a distance of about two miles, careful attention being paid to proper grade and alinement. On account of this excellent track it is possible for a 15-ton electric locomotive to bring out 100 mine cars with a capacity of two tons each, or including the weight of the locomotive itself, about 300 tons. The ordinary trip in this instance, however, is about 80 cars. There are in the region many other installations accomplishing equally good results.

Machine Mining

According to F. W. Parker, statistician of the United States Geological Survey,

there was mined by machines in the United States during the year 1910, 174,012,293 short tons of bituminous coal, an increase over the previous year of 31,515,415 short tons, or 41.7 per cent. The rapid growth of machine mining in the past ten years is decidedly gratifying to everyone interested in the industry, not only as an indication of progressiveness in the matter of lowering the average cost of production, and as a conservation measure, but also as tending toward increased safety of the men working at the face by reason of the discontinuance of shooting off the solid. Properly conducted machine mining, particularly where chain undercutting ma-

Coke Ovens, Moss Creek, Cambria County, Penn.



Mouth of Main Entry at Ehrenfeld, No. 3 Mine

chines are used, results in an increased yield of large coal and a decided decrease in the amount of coal, too often wasted by being thrown into the gob when solid shooting is permitted. According to my observation and experience, chain undercutting machines are to be preferred where the bottom is reasonably smooth and uniform, but in the B or Miller bed, in central Pennsylvania, this is not usually the case, as rolls or "horsebacks" are frequently encountered. Where this condition exists, punching machines driven either electrically or by compressed air, are preferable.

Questions are frequently asked as to what saving in mining cost may be effected by installing mining machines. It is not possible to give a flat figure that can be generally applied because the mining conditions are of such a varied character that methods found successful in one mine or bed, will be found unsuitable elsewhere, but from considerable experience, I think it safe to say that where properly handled an economy of about 10c. per gross ton below the pick mining rate is possible of attainment.

I have in my possession detailed figures of the mining cost at two operations, one where all of the coal is cut by electric chain undercutters, and the other where all of the coal is cut by air-driven punching machines. The pick-mining rate for the year when these statements were compiled was 62c. per gross ton.

Electric breast machines, output for one year 321,808 gross tons.

	Per Ton
Labor	$0.4134
Material	0.0259
Insurance and taxes	0.0009
Depreciation	0.0091
Interest charges	0.0025
	0.4518

Compressed-air punching machines, output for year 99,207 gross tons.

	Per Ton
Labor	0.4810
Material	0.0211
Insurance and taxes	0.0095
Depreciation	0.0132
Interest charges	0.0036
	0.5284

These two examples cannot be taken as a general average, because in the instance quoted where chain machines are used, the mining conditions are rather exceptionally favorable. In the other case, where punching machines are used, the conditions are about the same as the general average in that field.

Unprofitable Production

Notwithstanding the progressiveness and energy displayed by the operators of the central Pennsylvania field, they have for the past four years labored under insuperable difficulties, due to the great increase in producing capacity of mines in this and competing fields where the cost of production by reason of more favorable mining and geological conditions, is lower. It is contended by many of the operators in central Pennsylvania that they do not enjoy as fully as they should, the natural advantage the region has in lying nearer to the seaboard and the New England market than any other considerable field of bituminous coal. Based on the belief that the freight rate is discriminatory against central Pennsylvania, as compared with coalfields farther west, the Operators Association has recently brought a complaint before the Interstate Commerce Commission, from which it is hoped relief in this matter will result.

It is quite well known that in addition to this region others in the bituminous fields are suffering in like manner. The prices realized under the keen competition leave little or no margin of profit. It quite frequently happens that coal operators in preparing their cost statements, do not give sufficient weight to the items of "depletion of coal reserves" and "depreciation of plant and equipment," in other words, the monthly and annual statements of any coal-mining operation should invariably carry an item for amortization of capital account. This, of course, must vary according to the conditions at each particular colliery, but it should, under no circumstances, be omitted. Otherwise, the operator is almost certain to deceive himself.

Photographing Mine Maps

Mine maps should be made on more than one scale for convenience in handling, as well as for the psychological advantage that a small map fades the incidentals and brings the broad economic features to light. The larger companies are now photographing their big maps to reduce them to a more reasonable size, and to permit the filing of their records in a book about the size of a large sheet of typewritten paper, and an inch or so thick. The scale favored is 500 ft. to the inch.

The original to be photographed should be a tracing or map with unimportant details omitted. These details in a mine map will be the coal thicknesses, station marks, levels, progress dates, etc. The camera is set at a distance from the map so proportioned to the focal length of the lens that the reduction of the map is in some even proportion. The ratio can be so satisfactorily adjusted that old and new prints can be placed together, the break barely showing on the drawings.

The Consolidation Coal Company, Fairmont, W. Va., was one of the pioneers in the introduction and use of photography in coal-mine engineering. This company keeps its records as white prints and the officials are considering the construction of a graduated track on which camera display boards can be slidden, the lighting being by two pairs of mercury vacuum lights, in two reflecting cases set one on each side of the drawing.

Coal Handling at Power Stations

By Charles H. Hughes*

The handling of coal at power plants forms an important item in the total cost of power. The coal-handling equipments of four large New York plants are described. These are typical modern installations of recent design.

*82 Beaver street, New York.

One of the first considerations in locating a power station is accessibility from railroad and water connections, so that coal can be brought to it either by land or by water or if possible by both. The economical handling of coal is an important item in the cost of generating steam, which in turn affects the earnings of a company and the dividends which it can pay the stockholders.

The number of men employed should be kept at a minimum, and mechanical means adopted wherever feasible. Yet it is possible to use so many automatic and complicated devices that their cost may even exceed that of employing a large force of men; so the engineer, in laying out an installation, should make a careful study of the various steps necessary to get the coal from the car or barge, to the bunkers, selecting either men or machines, accordingly as they appear best suited for getting the coal to its destination in the quickest and most economical manner.

The coal-handling equipments described below were designed for some of the largest and most important power stations in New York and vicinity, and all, except the one at the Bush Terminal which is under construction, are in successful operation.

Hudson & Manhattan Railroad Power Station

The station of the Hudson & Manhattan Railroad, at Jersey City, N. J., supplies electric power for operating the trains in the Hudson companies' tunnels, connecting New York, Jersey City and Hoboken. It is advantageously located, being not only in the center of the distributing system, but also accessible to the railroads entering Jersey City, which makes it possible to ship coal directly from the mines to the station.

At present the station contains eight 900-h.p. Babcock & Wilcox boilers, the complete installation calling for 16. The boilers are all on the same level, and over them are the bunkers, having a capacity of about 4000 tons. Coal is dumped from the cars into hoppers, from which it is taken by conveyers and skip hoists to the bunkers. There are two separate duplicate systems, each having a capacity of 60 tons an hour.

FIG. 1. CABLE SYSTEM WORKING IN COMBINATION WITH HOIST AT PENNSYLVANIA RAILROAD POWER STATION, LONG ISLAND CITY

Referring to Fig. 2, cars are run into the low building in the foreground, and the coal emptied into the hoppers below, of which there are four, two under each track. As the systems are in duplicate, two of the hoppers belong to one system and two to the other. Each hopper is provided with a pusher feeder for regulating the flow of coal onto two (one for each system) 30-in. Robins belt conveyers, which rise at an inclination of 20 deg. to the tower in the station about 100 ft. away from the cars. The belts are driven by an electric motor.

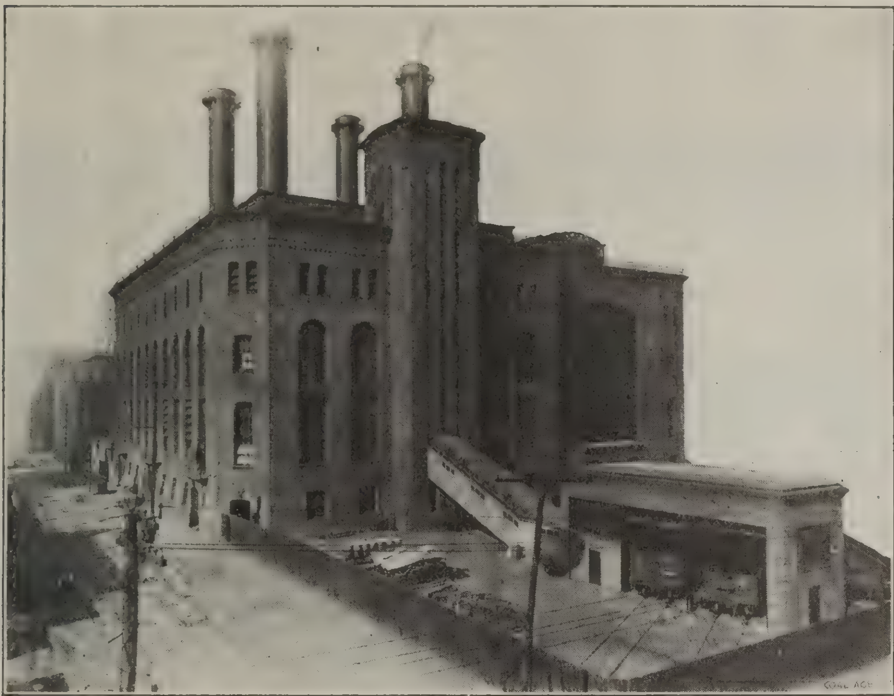


FIG. 2. POWER STATION OF HUDSON & MANHATTAN RAILROAD AT JERSEY CITY, N. J.

When the coal reaches the tower it falls from the belt into a hopper, at the bottom of which is a grizzly that separates the large pieces from the small, the large going through a crusher and meeting the small in another hopper. This hopper has gates communicating with either one of two weighing hoppers.

After weighing, the coal is dumped into receiving hoppers, provided with gates feeding into skips. These skips are raised 125 ft. to the top of the tower, and then discharged into the main distributing hopper. The gates in the receiving hoppers are opened and closed by the skip-hoist cars, the hoist being electrically operated.

The distributing hopper has spouts which feed into each wing of the station. The distributing conveyers of each wing are alike and consist of two 14-in. Robins belts running longitudinally over the bunker on opposite sides and a 16-in. belt which supplies one of the 14-in. conveyers just mentioned. Where necessary, automatic trippers are installed to discharge the coal into any desired part of the bunker, as shown in Fig. 3.

Either one of the systems, or both, can be operated by one man standing near the weighing hopper scales which are located in the tower at the basement or street level.

FIG. 3. BELT CONVEYER OVER BUNKERS AT PLANT OF HUDSON & MANHATTAN RAILROAD COMPANY

COAL POCKET FOR THE BUSH TERMINAL

The coal pocket shown in Fig. 7, located at the Bush Terminal, Brooklyn, N. Y., has a capacity of 3500 tons, the coal being used in the power station and for other purposes. The building is of reinforced concrete, the bins being elevated so that wagons can be driven beneath them.

The coal is brought in on the railroad track which runs parallel to the pocket at an elevation of about 9 ft. below the driveway, and is discharged from the cars to a scale weighing pit. From this pit it is drawn off by valves to a feeder, which fills the conveyer buckets running below it, and is so constructed that no coal is spilled during the operation. By means of the conveyer, the coal is elevated and discharged into the bins.

The conveyer consists of a number of sheet-steel buckets 30 in. wide and 35 in. on centers, suspended between steel links 17½-in. centers and carried on 20-lb. T-rails by 6-in. wheels. Each bucket can hold about 300 lb. of coal, and when running at a speed of 40 ft. per min., the conveyer has a capacity of approximately 120 tons of coal per hour.

On the vertical runs, the rails and guides are omitted, as the conveyer hangs in a plumb line. At the corners or turns are two revolving wheels, Fig. 4, mounted on the same axle, and suitably supported by brackets. These wheels engage the 6-in. rollers on the conveyer chain and are revolved by them, thus reducing the friction to a minimum. The buckets always hang in a vertical position between the revolving wheels.

An interesting feature of this installation is the fact that on the vertical run

of the buckets the chain is twisted at an angle of nearly 90 degrees. Thus, the buckets shown in Fig. 4, which is a view at the bottom turnwheel, are, at the top, turned at right angles to the position shown. This is one of the important features of the Hunt conveyer which is here used.

The driving mechanism located over the pockets, Fig. 7, consists of a pawl driver, run by a belt from a 25-h.p. electric motor. Intermediate between the pawl driver and the pulley, are accurately cut gears, which are entirely incased in an oil-tight compartment and run in a bath of oil. Pawls on the driver engage studs between the links on each side of the conveyer in such a manner that a continuous and smooth motion is given to the chain. Variation in the length of the links, due to wear, does not affect the smoothness of running.

Referring to Fig. 5, which well illustrates the driver, it will be noticed that just in front of the driver a bucket is being discharged. This is accomplished by a dumper, several of which are placed along the upper run of the conveyer. The dumper consists of two cams which are mounted on a shaft and engage cams on both sides of the buckets. The conveyer, moving along the track, causes each bucket to successively engage a dumper, thereby emptying the bucket. A dumper can be attached anywhere along the line and can be easily disengaged by throwing back the lever, which remains in this position without further attention until required again. This coal-handling machinery was built and installed by the **C. W. Hunt Co.**, West New Brighton, N. Y.

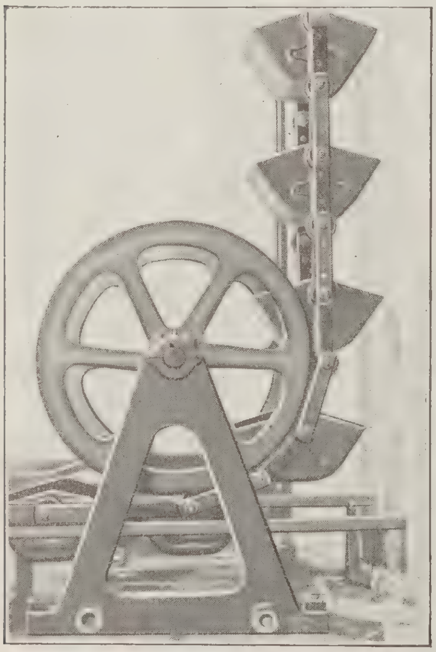

Fig. 4. Hunt Bucket Conveyers, Bush Terminal, Brooklyn

Long Island City Power Station

The station located at Long Island City, on the East river, which furnishes the electric energy for the Pennsylvania tunnels, is one of the largest in the country, having an equipment of 32 Babcock & Wilcox boilers. It is of the double-decked type, the boilers being set in batteries of two, eight batteries on the first floor and eight on the second directly over those below. Over the second tier of boilers is the coal bunker.

To design a coal-handling plant for a station of this size, required careful study on the part of the engineers. Since the station was located on the East river, advantage was taken of this fact, to bring in the coal by barges. From these it is hoisted and run into the bunkers by means of a cable railway.

A steel tower (shown on front cover of this issue of Coal Age) was built on the dock. In the lower closed portion, is an engine for hoisting a two-ton clam-shell bucket from the barge to the boom on the tower, an engine for opening and closing the bucket, and another for running it, after it has been hoisted, to the discharge hopper in the tower. The top of the tower is 190 ft. above the dock, and the boom 170 ft. above the water. The machinery for hoisting and trolleying was designed and installed by the Robins Conveying Belt Company. The

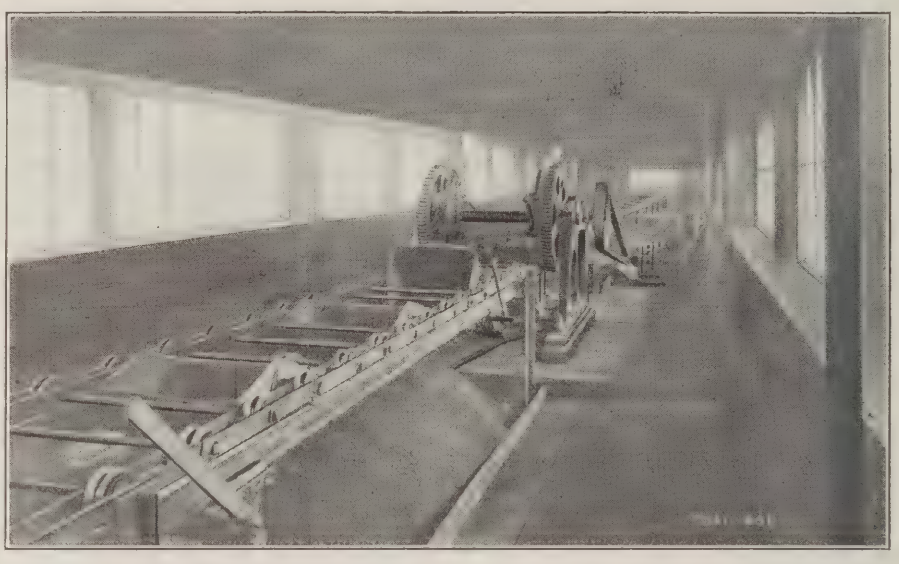

Fig. 5. Showing a Driver and Conveyer Buckets Operated by an Electric Motor

Fig. 6. Coal Is Conveyed from Tower to Power House on Two Inclined Robins Belt Conveyers

bucket can make a round trip in 45 sec., that is, it can be filled, hoisted, emptied and dropped in that length of time. The tower is operated by one man.

On the upper part of the tower is another inclosure, in which is a hopper, and below it a crusher. Chutes from the crusher take the coal to a weighing machine, and then to the delivery hopper.

A Steel Bridge Is Used

From the tower to the power station, a distance of about 500 ft., is a steel bridge over which cars are drawn by a cable, as shown in Fig. 1. The cars, after being filled at the tower, travel over the bridge, enter the top of the power house, pass down one side over the bunkers, make a half turn at the far end, pass along the other side and then cut onto the bridge again, which at the tower has another half turn. A car travels about 2500 ft. in making a complete trip.

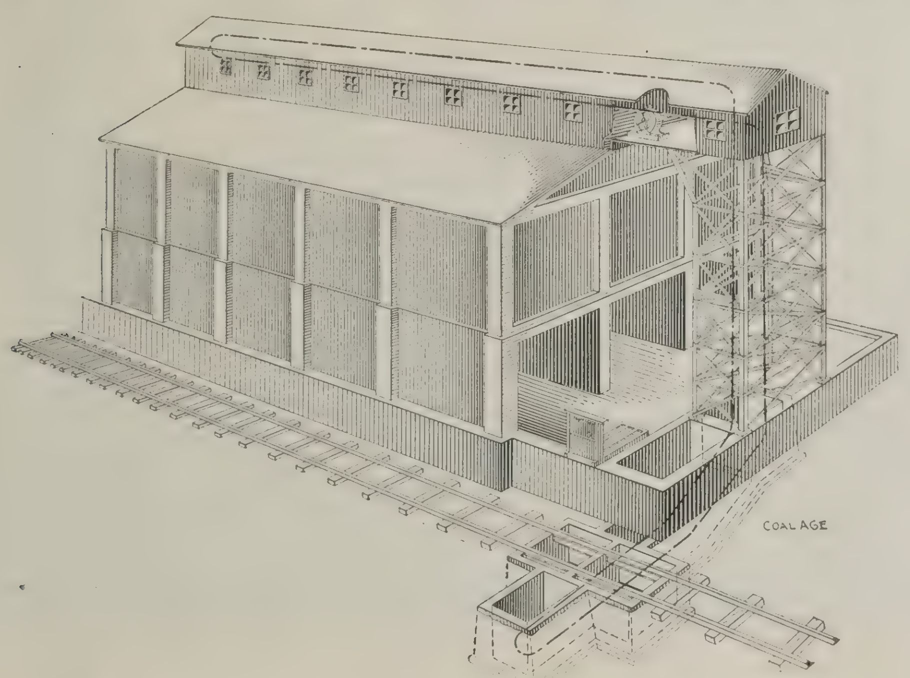

Fig. 7. Reinforced-concrete Coal Pocket at Bush Terminal, Brooklyn

When a car is to be filled at the tower, its clutch is temporarily released from the cable and the car stopped under the feed hopper, the doors of which are opened by the operator. As soon as the car has been filled, the clutch is thrown in, and it travels along with the cable, to the bunkers. At various places over the bunkers are trippers which catch projections on the cars and open the doors on both sides, the coal dropping in two streams into the bins below. As soon as the car passes over the tripper, the doors are automatically closed and the car continues around the track to the tower on the dock. In discharging, the car is not stopped but travels on as if still loaded. The trippers can be placed anywhere, so that any desired bin can be filled.

The cable railroad, when operating 29 cars at a speed of 180 ft. per minute, has a capacity of about 150 tons of coal an hour.

Kingsbridge Power Station

Still another type of coal-handling equipment is in use at the Kingsbridge power station of the Metropolitan Street Railway Company. This station, like the one at Long Island City, has its boilers arranged in two tiers, the bunkers being over the upper tier, and is located near the water so that coal is brought to it by barges.

From a tower, Fig. 6, extends a boom, about 100 ft. above the water. This supports a bucket that is raised and lowered by a steam engine, and drawn by another engine to and from the tower. In raising the bucket a speed of 1500 ft. per min. has been obtained, but under normal conditions three trips per min. are generally made. The tower has a capacity of 200 tons of coal per hour.

The coal after being raised and brought into the tower is discharged into a crusher, and thence into a hopper that in turn discharges onto two Robins belt conveyers which enter the station at an incline, and are housed as shown in Fig. 6. It will be noticed that the housing is at the center of the building. One of the inclined conveyers discharges onto two conveyers extending to the right over the bunkers, and the other onto two running to the left over bunkers, the coal in each being piled up into two separate piles. By means of trippers, the coal can be discharged at any desired point.

Electric Lamps in Mines

R. A. S. Redmayne, the British chief inspector of mines, as a result of the Whitehaven explosion, became convinced of the adaptability of electric safety lamps for use under certain conditions. At his request Robert Nelson, the electrical inspector of mines, was commissioned to investigate this subject. It is believed this is a matter of general interest to coal men and a brief summary of Mr. Nelson's report is given here.

The main disadvantages of electric lamps, apart from some constructional defects, is that they will not, without a cumbrous and delicate attachment, detect the presence of explosive gas. Then there is the switching difficulty, some of the lamps having an external switch which may spark in making and breaking. Several ways of overcoming this are possible:

1. To use a lamp with a liquid battery, so designed that the light is switched on or off by simply turning the lamp over. Such a lamp may be made cylindrical in shape so that if held, or placed with one end uppermost it lights, but if held with the other end uppermost it is dark.

2. The battery may be of the ordinary dry "primary" type. It would be easy to arrange a pair of contacts, fixed inside on the bottom of the lamp, with a corresponding pair of contacts on a loose dry cell. Then, again, when the lamp is upright it will light, placed bottom uppermost it will be dark.

With either of the above lamps, Mr. Nelson explains, the possibility of igniting gas would only occur if a lamp bulb should be broken in an explosive mixture. With the battery cracking or breaking the outer glass *alone* is not immediately dangerous.

A further constructional defect it is desirable to remove is that most electric safety lamps give a sort of search-light effect and a rather worse general lighting effect than an ordinary oil safety lamp.

In conclusion Mr. Nelson says the disadvantage of electric safety lamps named above, as far as he is aware, can only be minimized at present, not removed. An apparatus on the same principle as the Holmes Alderson electrical firedamp detector* (which is automatic in its action) might be utilized in each district worked by electric safety lamps. A few of the electric safety lamps in use, those in the hands of deputies, might as a means of occasionally testing for gas be fitted with firedamp detectors.

The total capacity of the anthracite storage plants of the United States is a little over 5,500,000 tons, or nearly 8 per cent. of the anual production.

*The Holmes Alderson automatic firedamp cut out was described in *The Engineering and Mining Journal* under date of March 4, 1911.

The Adrian Mine Explosion

By R. Dawson Hall

This explosion resulted in the death of eight men. Six succumbed to afterdamp and two were killed by the violence of the blast. The cause of the explosion is mysterious, but it may have resulted from a short-circuit following a roof fall.

The Adrain mine is situated about two miles north of Punxsutawney in Jefferson county, Penn. The explosion, which occurred there on the morning of Thursday, Nov. 9, as the men were entering the mine to go to work, was of a mild order, but resulted in the death of eight men. Two of these were killed by the violence of the explosion and six others, working about ¾ of a mile away, and located in another split, were overcome by the noxious gases contained in the afterdamp and died before they could be reached.

Description of the Mine

The mine was opened in 1886. Adrian was one of the best equipped mines in the section at that early date. But today it lacks that outward pretense and exhibit of permanence which characterizes

Power Houses and Fan at Adrian Mine

modern mine developments. It is needless to add that since the time of its opening, a quarter of a century ago, there has been extended development until today the workings cover roughly some 8000 acres. The mine is operated by the Rochester & Pittsburg Coal and Iron Company.

The coal bed mined is the Lower Freeport. In this mine the average thickness of the bed is 6 ft., though there are occasional places where the coal runs as low as 3 ft. 2 in. and as thick as 7 ft. For those who are not well acquainted with central Pennsylvania, it may be added that the coal is a bituminous bed of good quality and excellent for coking. It lies near water level at Adrian and is reached by a slope of which the portal can be seen in an accompanying illustration. The mine is situated 8 miles west southwest from Sykesville, where an explosion occurred on July 15 of this year, causing the death of 21 men. An account of this disaster appeared in the Prospectus number of Coal Age.

Adrian had an explosion about 15 years ago and two men belonging to an exploring party were killed. Edward W. Robinson, who was then superintendent, nearly lost his life on that occasion. Many years ago there was some trouble with gas in the 9th Left and in the 8th Right. In the latter heading, operations were suspended till the men were supplied with safety lamps. An erosive fault appeared and to its occurrence the presence of gas was, with good reason, attributed.

The Last Mine Inspection

The recently appointed inspector, T. A. Furniss, soon after his appointment, knowing that there was gas in mines nearby, determined to make a complete examination of Adrian mines. He was especially anxious to determine the condition on the tops of falls and in abandoned sections of the mine. He noted and recorded all his observations, which covered from 50 to 60 separate places. In all he was unable to find gas. He spent four days at Adrian, Sept. 1, 5, 6 and 7, and some weeks in nearby mines. In Adrian he found no gas and reported that the ventilation was good in all sections.

The fan is a Capell, 16 ft. in diameter with blades 8 ft. wide. When the inspector made his report the fan was making 130 r.p.m. and producing a water gage of 1.8 inches.

The air at the fan measured 102,375 cu.ft. per min., and was divided into six splits as in the following table:

AIR COURSING ADRIAN SPLITS

Split No.	Cubic Feet per Minute at Last Cross-cut	Men in Split	Cubic Feet per Man at Last Cross-cut
1	12,864	49	262
2	19,384	55	333
3	12,296	60	204
4	15,696	54	290
5	10,080	41	354
6	21,600	70	308

The Origin of the Explosion

For a long time after the explosion there was an expectation that its origin would be discovered. It was confidently reported that Mike Dehannis, cutter, and Paul Sinoski, his scraper, were the innocent causes of the disaster, but now that they have been found, the tendency is toward placing the source of the ex-

plosion elsewhere, perhaps at a point a quarter of a mile from where their dead bodies were discovered.

It is customary to find a cause for all explosions, that cause being often determined by the personal predilections and needs of the investigator. Here, however, if neither Sinoski nor Dehannis set fire to the gas the explosion must have been due to short-circuiting of a haulage wire or possibly to the leaving of dynamite or caps within the mine, despite the fact that the use of dynamite is forbidden except for the shooting of rock headings. The cause is in any event not obvious. There was no fire in the mine before the explosion. There was probably none immediately afterward and none has been discovered. The explosion is a mystery, not alone in that the cause is not known, but because a cause is hard even to imagine.

The mine inspectors failed to find gas after the explosion though they made diligent search for it. Every effort will be made to ferret out the cause. The officials of the company desire to know it so as to safeguard the mines against a possible repetition of the disaster. The miners of Adrian are mostly foreigners, but many have grown up with the mine and it is a mystery to them how the explosion occurred. The men are all of a high type of citizenship; cleanly, hard-working, self-respecting, gradually absorbing the favorable surroundings of their environment.

Dehannis and Sinoski

It is a rule at Adrian mines that the entrance to the mine be protected by adequate locked gates till 6 a.m. These gates are guarded by a watchman. Meantime the mines are examined by the firebosses. This rule was followed on Nov. 9, the firebosses being William Haddick and William Maloney. Among the first to enter were Dehannis and Sinoski. They were working in the 13th Left which is reached by way of the 12th Left through a cross haulway known as the 6th East.

They did not, however, follow the regular haulway to their places, but went by way of the 12th Left and 10th East.. One man reached a point 50 ft. beyond the intersection of these headings. The other was found about 500 ft. further and was probably considerably in the lead. When they were at these points, the explosion must have occurred. Neither man was burned or even scorched. In fact, had they been five minutes later they would not have been killed by the force of the blast, for they were on the very edge of the territory where the severity of the explosion died out. But the gust threw one man flat on his face, where he lay till he was found with his face in the mud. The forward man was possibly thrown some distance and fell with his arm over his face, his skull being broken, his arm fractured and the heel of his rubber shoe cut off. Both men showed by their blackened appearance that much coaldust was being driven through the headings by the expelling current.

The Other Victims

Other men, whose work lay in the 2d East, off the old 9th Left, entered the mine about the same time as the two men mentioned. It appears that some arrived at their working places, stripped off their coats and started to work. About that time the explosion probably occurred. One man, Angelo Fornio, who escaped, declared that no noise was heard, but states that he was thrown against the timbers with sufficient force to raise a lump on his head. It appears that pails and coats in hand, the miners hastened down the heading. They were all foreigners.

How to Act in Afterdamp

From the survivers, who represented themselves as at first passed by others, it appears that those who ran the fastest were more speedily overcome. Those who left with moderate speed did not increase their pulse rate or enlarge the capacity of their inspirations or the number of their lung movements per minute. They therefore inhaled and absorbed less carbon monoxide and were enabled to travel further, passing seven of their companions lying prostrate along the heading. It has been said that due care not to hurry or in any way overwork in the presence of afterdamp is to be counselled, because hurry stimulates the lungs and the heart, and moreover draws heavily on the vitality of the impetuous runner or overworker.

Two men had presence of mind enough to stop, dip their handkerchiefs in the tea contained in the tanks of their dinner pails and carefully wrap their mouths with the damp rags. They are living to recommend such precautions to others.

The Motormen

The motormen arrived later. By that time, there was an appearance of smoke near the foot of the slope. This was accompanied by the smell of burning from the explosion. Some said it was merely fog and that the smell arose from the smoldering of a short-circuited, rubber-

Showing Head of Slope, Storage Bin for Ovens, and Abandoned Power Houses

covered cable. The boss motorman turned off the power, believing that such a broken circuit had actually occurred. But the men were not disposed to go in, the fog becoming denser, the smell stronger and the smell not resembling in any way the odor of burning rubber. Those who did go in soon concluded that safety lay in leaving the mine.

It must be explained that the ventilation is being provided by a blowing fan and the air consequently passes around the workings, using, as has been said, six splits, and leaves the mine by the main haulway. Thus the men entering the mine passed into the return airway. This must have contained much afterdamp, although the explosion having short-circuited the air in the affected districts, the afterdamp was being but slowly removed. In fact, it may be fair to assume that the air circulated mainly where the impurities were least in percentage. The brattices, which were all constructed of wood, were blown down over an area conservatively estimated as being a half mile square. Two doors perfecting a single stopping were down and the air of the explosion area was circulating its foul products through another split. The return, where all or part of the other four splits were discharging was not dangerously befouled by the afterdamp, and was used freely by the rescuers.

Improvised Rescue Corps

Anthony Goodlick and Mike Zuby and another foreigner induced Fred Hall to take them in on his motor, and together the four made a dash to save the seven men that Goodlick and Zuby had passed in leaving the 2d East. They gathered up an Italian, Fornio, and hauled him to the main slope, where he was transferred to a car and drawn up to the surface. Later he was successfully resuscitated. Three plucky men returned and started to bring out two others. Zuby and Goodlick caught hold of the prostrate forms and started to drag them to the motor. But the afterdamp, hard physical labor and increased heart action from excitement had already combined to weaken them. Leaving their friends for whom they had risked so much, they returned to the slope mouth in order to save their own lives and none too soon, for on reaching the main entry they fell down, Goodlick first and Zuby shortly afterward.

Official Rescue Work

Robert Maloney, the mine foreman, started to lead a rescuing party as soon as the news reached the surface. But every moment the return air was getting more foul, and he could not reach the places where the men were known to be.

The rescuing parties were soon augmented by the arrival of A. W. Calloway, general superintendent, R. B. Dick who superintends Adrian mine, and T. A. Furniss, the inspector of the 12th Bituminous District of Pennsylvania, of which Adrian forms a part. They built many canvas stoppings and, succeeding in driving the air up to the crosscut nearest to Room 22 in the 13th Left out of the 6th East, T. A. Furniss entered the above room. Returning, he found the others sitting silently along the side of the heading. There had been a fall somewhere, a large cave, which Mr. Furniss did not think boded them any good, and he spoke to the rest of the party about it, but no one answered, all being seemingly under a spell. Shouting to them, he roused them from their stupor, so that one and all followed his advice and example and proceeded to leave the vitiated heading as soon as possible, but thoughtfully keeping tally of each other.

Some think the air-current was reversed, but if so it was only temporarily. Probability favors the idea that the cave dislodged the afterdamp from the faces of rooms, which the newly established current of air in the heading had by no means, so far, swept clean. Fortunately Maloney managed to reach a door which, once opened, permitted a cleansing draft to sweep directly down the heading or otherwise it is to be feared that as too often happens, a rescue party would have contributed to the death roll. The party succeeded in making its way to the intake and were attended by the physicians at the mine mouth. Firebosses Haddick and Maloney, and D. Fleming, superintendent of the Eleanora shaft and John Metro nearly succumbed to the toxic action of the gas, but the opening of the door with its clean gust of purer air gave them strength enough to get out.

On returning to the surface, Furniss discovered that the Government Mine Rescue Car had not been wired for; all those present having such an earnest desire to see what *they* could do, that they overlooked the equipment at their disposal. At four o'clock the car was sent for. At that hour another corps entered the mine but at five o'clock all were withdrawn exhausted, the tally being taken to see that all, totaling 59, came out.

Inspectors Furniss and Lowther with a few men entered the mine at 8 p.m., exploring the 2d East out of 9th Left. They found the bodies of six men. These bodies were hauled to the surface later with the aid of the corps from the U. S. mine rescue car. Search was resumed for Dehannis and Sinoski, but without result.

Government Rescue Car

The rescue car of the Bureau of Mines arrived shortly after 11 p.m. The 4:15 p.m. train on the Buffalo, Rochester & Pittsburg Railway was held for it for half an hour, but being late it lost time all along the road and arrived two hours behind schedule. J. T. Ryan, the engineer in charge, had a crew of four men. At 11:30 they entered the mine, having four oxygen helmets and a pulmotor. They also had canary birds with them. When the canary bird with the foremost observer gave unmistakable signs of the presence of afterdamp, that section of the party retreated to better air. Four donned their helmets and explored the face of the 13th entry and the last two rooms. It was anticipated that the men would be in these rooms and their machine was found at that point, but no trace was found of their bodies. The party then returned to the limit of circulation. Under Inspector Lowther's supervision the circulation was carried up to the face and thereupon the remaining seventeen rooms were in-

View of Slope Portal at the Adrian Mines

spected without helmets, advance being made with canary birds as indicators.

For two nights and a day, with crews of men turning over rock falls the company endeavored to find Dehannis and Sinoski, but without success. Men do not always remain in their places and the most unlikely places were searched, with almost as much diligence as the more probable. They were supposed to be the igniters of the gas or coaldust and the center of violence concentrated around the rooms it was their duty to cut. So 13th Left was searched with closest scrutiny.

At last, questioning their agency in the explosion, inquiry was made as to their habitual way of going to work and they were soon found, uncovered and easy to be observed, close by roads which had been much traveled by searching parties.

COMPANY STORE AND POST OFFICE AT DELANCEY, PENN.

The Mildness of the Explosion

One fact shows conspicuously in the annals of mine disasters in Clearfield and Jefferson counties. All explosions are comparatively mild. The DuBois, Sykesville, Eleanora, Ernest and two Adrian explosions were all of light character. This explosion lifted two cars partly off the track, blew down rock and demolished wood brattices; but partly because of its unlimited chance for expansion and partly because the coaldust did not materially aid its operations it did not manifest any force at the fan, which continued its revolutions without cessation. The relief door was off, and light slats were nailed over the opening. These were not blown away.

The Rochester & Pittsburg Coal and Iron Company are extremely anxious to avoid explosions. Inspector Furniss on his appointment suggested the introduction of clay-stemming and permissible powders. The company readily agreed to install the first at once and the second as conditions warranted. Many men were using permissible powders at Adrian at the time of the explosion. But as has been seen, the explosion arose from other causes than blasting.

Illinois Coal Mining Statistics

The following is a summary of the Illinois coal statistics for the fiscal year ending June 30, 1911, prepared by the Bureau of Labor Statistics.

During this period the Illinois mines have produced 50,165,099 short tons, which is an increase of nearly 1,500,000 tons over that of the previous year. Of this amount 13,025,663 tons were mine-run coal, and 19,588,409 tons were lump coal, the remainder being egg, nut, pea and slack.

The average value per ton of all grades at the mines was \$1.101, which is an increase of about 10c. above that for last year. The aggregate home value of the total product was \$56,034,494, which is an increase of about six million dollars above that for the previous year.

There are 845 mines and openings of all kinds; of this total, 184 were opened during the fiscal year, and 217 were abandoned. The average number of days in active operation for shipping mines was 169, which is 10 less than for the year previous.

The number of mining machines in use during this period was 1430 and the number of motors in use underground was 316. These figures both show appreciable increases over that of the year previous. The number of tons undercut by machines was 20,191,865, while the number of tons mined by hand was 29,973,234 tons.

The total number of employees at the mines doing this period was 77,410, which is an increase of nearly three thousand over that for the same period last year. Of this number 70,973 were employed underground, and 39,912 were miners.

The average price paid per ton for hand-mining was 62.7c. which is an increase of exactly 3c. above that for the same period last year. The average price per gross ton for machine mining was 49.4c., which is also an increase of nearly 3 cents.

The number of men accidentally killed at the mines was 157, of which 149 were killed inside the mine. Eliminating the large loss of life at the Cherry disaster, these figures both show appreciable increases over that for the same period of last year. The number of men so badly injured as to lose a month or more work was 709, which is a reduction over that for the same period last year.

The number of tons mined per life lost was 319,523, and the number of employees for each life lost was 493. The number of deaths per thousand employed was 2.03, and the number of men killed for each million tons produced was 3.1, which is identically the same as for last year, eliminating the victims of the Cherry disaster.

Nation's Coal Production

The United States Geological Survey has issued its annual coal chart, showing the production of coal by States from the year 1814 to 1910. The figures relate a wonderful history of growth. In 1814 a total of 22 tons of coal was produced in Pennsylvania. In 1815 the percentage of increase was good, but still only 50 tons were taken out. By 1825 over 100,000 tons were mined in the two States producing. In 1850 the figure had reached 7,018,181 tons. In 1876 it was 53,280,000 tons. At the end of the century it was 269,684,027 tons. In 1905 it was 392,722,635 tons. In 1907, which it was supposed would remain the record year for some time, the production was 480,363,424 tons, but in 1910 the enormous total was reached of 501,596,378 short tons, a production larger by far than that of any other country in the world. So steady has been the increase in American coal production that most of the years have been record breakers. The total production since 1814 has been approximately eight and a quarter billion tons.

The greatest difficulty in the manufacture of briquets is to secure a cheap binder. When the difference between the price of slack and first-class coal averages \$1, the cost per ton of briquetting must not exceed this amount, which means approximately 40c. for manufacture and 60c. for binder.

Breathing Apparatus

The following table gives the conclusions of the British Royal Commission on the efficiency of breathing apparatus. English specialists are inclined to look upon breathing apparatus rather as an assistance to recovery work than as an actual life saving agency. The commission considered the Draeger apparatus heavy and uncomfortable to wear, hot and liable to catch on rough surfaces or timbering. Experience has shown the ½-hour Draeger to be more practical for use under mine conditions than the two-hour form as it weighs less, about 14 pounds as compared with 42 pounds, is cooler, does not interfere so much with the eyesight, has no chin valve to close, is quicker to adjust and there is no trouble from adjusting a helmet to the face. It is also better adapted to such work as renewing stoppings, etc.

CONCLUSIONS AS TO EFFICIENCY OF BREATHING APPARATUS

Apparatus	Weight in Pounds	Oxygen Capacity in Liters and Cubic Feet Lt.	Cu.Ft.	Removal of Carbonic Acid Gas	Supply of Oxygen	Air Tightness	Comfort and Convenience
Pneumatogen type III	14½	163	(5.8)	good	poor	good	Very good
Draeger	36–39	251	(8.9)	good	good	good	bad
Westfalia	36	274	(9.7)	bad	good	good	good
Fleuss	31	228	(8.0)	good	good	good	good
Weg	about 30	150	(5.3)	good	good	good	good
Aerolith	22			fair	good	good	very good

A Barometer for Mines

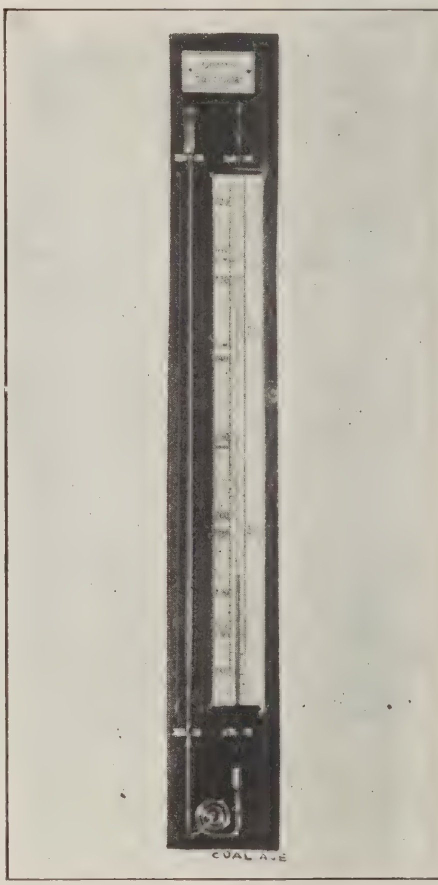
The important influence which the state of the atmosphere has upon the conditions of safety in coal mines, particularly where these mines are of a dry or gassy nature, is well known to every practical colliery man. It is the custom, in the coalfields of Great Britain, to issue colliery warnings by means of the public press, when the barometric conditions are such as to render an increase of danger probable, and every colliery manager recognizes that a careful study of the barometer is one essential of safe working.

For this reason it is of interest to refer to a barometer of increased sensibility which has been developed by the mining faculty of the University of Manchester, England, under the direction of Prof. G. H. Winstanley, whose work in mining research is so well known. This, as made by Otto Baumbach, is shown in the illustration. The feature of this barometer, known as the "Contra," is that the movements of the mercury siphon barometer are magnified through a light liquid. This liquid rests on the lower mercury column, which terminates in the narrow capillary tube, seen to the right of the figure, and which is provided with a suitable scale. The spiral, which is the only difference in shape from the ordinary siphon barometer, is only inserted to act as a safety trap, in order to prevent the light liquid from diffusing into the vacuum of the upper mercury chamber.

It is, of course, evident that the readings of the liquid in the narrow capillary tube are caused by the mercury in the lower siphon, and hence these readings are in reverse order to the readings of an ordinary mercury barometer. The graduation, which is from ten to twelve times as long as that of an ordinary barometer, is calibrated so that the readings in all parts of the scale coincide with those of the standard barometer. They can be observed easily at a distance. Each interval (10 to 12 mm. long) corresponds therefore with one millimeter on the mercury barometer.

The chief advantage of the "Contra" barometer is the readiness with which the smallest change in atmosphere pressure can be observed during unsettled weather. The ease with which it can be read renders it eminently suitable for use in connection with mines, while for most purposes it is well adapted to the requirements of laboratories.

In installing the barometer, it is placed vertically on the wall and a stopper, which in transit is placed on the top of the capillary tube, is replaced by a dust protector. A tap, which is provided to secure the liquids during transit, is then opened and the light liquid, which for convenience in reading is colored red, is allowed to come to a standstill. The barometer is then brought very slowly to a slanting position in order to allow all the small portions of mercury and red liquid to combine, after which it is brought back to the vertical position.



The Contra Mine Barometer

It is very important that while the barometer is in operation it should not be taken from its position on the wall. If, however, from any cause, the barometer has to be moved, it is brought very slowly to a slanting position until all of the mercury has filled the left-hand tube, after which the tap, which is used in transit, is closed. It is most important to bring the barometer slowly and gradually from the vertical to the horizontal position, in order to allow the mercury to fill the top of the left-hand tube. With these precautions in moving the instrument, the apparatus works in a perfectly satisfactory manner, giving greatly magnified scale readings which are a distinct asset to the mine manager.

Resistance of Iron to Rust in Concrete

According to the *Review Scientifique*, xlix, 1, 23, an old building in Hamburg was recently demolished, from which the behavior of iron inclosed in cement could be judged. This was an old gasometer, the foundations of which rested on several pillars. The iron anchors were immersed in cement grouted to a good thickness. The 60 bars, each 2½ m. long, which formed the anchors, were examined. and were found to be perfectly well preserved. They still showed their outer bluish skin and no trace of rust. This gasometer was built between 1852 and 1855, so the iron bars had been fully 50 years in the concrete. This protection from rust can be explained by the fact that the dampening of the concrete had produced a strongly alkaline reaction, and that iron, when surrounded by alkali, is inoxidizable.

Experience has shown that it is unwise to put trust in even a good system of vaporizing to lay mine dust and prevent the extension of explosions, where extensive gobbing is practised, as wide gobs mean the accumulation of much dust which cannot be effectively dampened by any known system of wetting.

The Appointment of Firebosses

Special Correspondence

Great Britain is contemplating the passage of stringent laws regulating the appointing of firebosses. Particular attention is to be given the physical qualifications of the applicant, especially as regards eyesight and hearing. The matter is being actively debated, not only by the labor organizations, but the owners' and managers' associations as well.

There is abundant evidence that the mining people in Great Britain are taking a real and deep interest in the Coal Mines Bill. The terms of this bill, as amended by the select committee, will be discussed generally and in detail by the House of Commons ere this bill is passed on to the House of Lords for formal and final ratification—if, indeed, such stage is reached by the present Parliament.

The Proposed Law

As an example of the interest and excitement aroused, it may be mentioned that many educational authorities have been arranging special courses of instruction on mine gases and gas testing, the growing importance of which is emphasized by the conditions imposed by clause 15 of the bill, which now reads:

(1) A person shall not, after Jan. 1, 1913, be qualified to be appointed, or to be a fireman, examiner or deputy[1] unless he

(a) is twenty-five years of age or upward, or is the holder of a first- or second-class certificate of competency, and

(b) has had at least five years' practical experience underground in a mine, of which not less than two years shall be at the face of the workings of a mine, and

(c) has obtained a certificate from a mining school, or other institution or authority approved by the Secretary of State, as to his ability to make accurate tests, so far as practicable, with a safety lamp, for inflammable gas, and to measure the quantity of air in an air current, and that his hearing is such as to enable him to carry out his duties efficiently, and

(d) has within the preceding five years obtained from such approved school, institution or authority as aforesaid, or from a duly qualified medical practitioner, a certificate in the prescribed form to the effect that his eyesight and hearing are such as to enable him to carry out his duties efficiently, the expense of obtaining which shall, in the case of a person employed at the time as fireman, examiner or deputy, be borne by the owner of the mine;

Provided that:

(i) the requirements of paragraphs (a) and (b) shall not apply to any person employed as a fireman, examiner or deputy at the date of the passing of this act; and

(ii) a person shall not be required to obtain a certificate as to ability to make tests for inflammable gas, or as to eyesight, if he is employed in a mine in which inflammable gas is unknown.

(2) The certificate as to eyesight and hearing of a fireman, examiner or deputy employed in a mine shall, while he is so employed, be deposited with the manager, who shall, whenever required to do so by the inspector, produce the certificate for his inspection.

[1]In various centers this underground official is designated fireman, examiner or deputy.

As Viewed By the Miners

As compared with the requirements of the existing act of 1887, the qualifications required by this new clause are looked upon as revolutionary. Many of the present-day firemen anticipate that their positions as officials will be lost under the "eyesight" and "hearing" tests, which they accordingly condemn. This will mean the appointment of new men to fill the vacancies, necessitating so far as they are concerned, a course of instruction in mine gases, etc. This is the cause of the extensive preparations now being made, and in certain quarters it is being whispered that even if the new coal-mine bill fails to pass the House of Commons, the Home Secretary may put through an order covering the points contained in clause 15, and thus insure the raising of the qualifications of the firemen. If it should happen that such a procedure is followed, the order made will be as binding as though it were embodied in the principal act, as is exemplified by the explosives in the coal-mines order.

It is not surprising, therefore, that the matter is attracting considerable attention, not only among the educational authorities, but the Association of Colliery Firemen, who are also actively discussing it. In various parts of the country there are colliery firemen's associations in existence, which are combined in one national federation some twelve thousand strong, having as one of their main objects the raising of the standard of education among colliery firemen. The Lancashire Association, in September, engaged instructors to give the needful tuition at three different centers in the county, and therefore, the members should have no difficulty in retaining their posts should clause 15 become a law.

A Mine Inspector's Views

In Yorkshire, classes for colliery firemen have been held for some time, and J. Mellors, H. M. Inspector of Mines, attended a gathering at Wakefield when the certificates were presented. He found that all the men had risen from the ranks, and he told them he felt proud to be able to hand certificates to men like that, because, with the certificates they would be better miners and citizens. It was matter for regret to find, in the course of his calling as a mine inspector, that every man was not able to detect gas in the safety lamp. Miners, when aware of the presence of gas in the mine, should have a wholesome appreciation of their danger and go out, or to a place of safety. Further, he hoped they would go on and fix a high standard, as there were men who had risen from the ranks to the position of general manager, and that ought to be encouragement to them.

Mr. Mellors told how he had been obliged to walk a distance of 10 miles to attend a technical class. Now there are classes for miners everywhere, education being literally thrown at them, and there is no reason why any man with energy, should not rise to be a colliery manager if he will put his shoulder to the wheel and take advantage of the educational facilities now offered.

The Royal Road to Success

"Therefore," Mr. Mellors said, "persevere, and let your guiding star be safety of life and limb." He remarked that they are practical men, and should qualify to be scientific as well. One of the brightest stars they had, not only a Bachelor, but a Master of Science, was, only a few years ago, working at the coal face. It was a proud thing to be able to rise from the ranks. There was no difficulty about it other than self-denial. It could not be done, however, if they had three or four things all proceeding at once; to succeed they must have but one object in view. The one royal road to success was downright hard work. If miners all worked with that object in view, there would be fewer of the lamentable accidents which they read about today. If men would only qualify themselves to distinguish the safe places from the unsafe, they would be able to look after themselves without having to trust to deputies.

VIEWS OF THE MANAGERS

When the members of the South Staffordshire branch of the Colliery Managers' Association met on Sept. 25, President J. W. Liddell referred sympathetically to the objects sought to be attained under the new coal-mines bill. A distinct change has taken place since the time of Lord Shaftesbury's agitation on behalf of the miners, and since the time when Mr. Tremenheere was appointed by the home office to inquire into the conditions of mining life. Female and child labor have been abolished and restrictions upon mine working have been enacted by the legislature.

Nevertheless it is alarming to know that the death rate has gone up in recent years. The authorities are anxious to arrest the upward tendency, and with that idea they all concur. The new bill is an attempt to create conditions in regard to mining work, which will tend to enhance the safety of the miners. It seeks to place the miner in a position which will make his dangerous calling less hazardous. A law of this kind is a benefit upon the whole community, and Mr. Liddell sincerely believed the bill in its final form would, in a far greater measure than its predecessors, fulfil its grand objective.

W. G. Phillips, in discussion, acknowledged the fact that modern practice in mining, especially the large increase in the areas worked, sometimes covering as much as 10,000 acres, renders new legislation necessary, the introduction of electricity alone making such a change almost imperative. Clearly, wherever the gaseous condition of the air renders safety lamps necessary, there should be no exposure to electricity. Mr. Phillips believing that no motor has been invented which can be so used with safety.

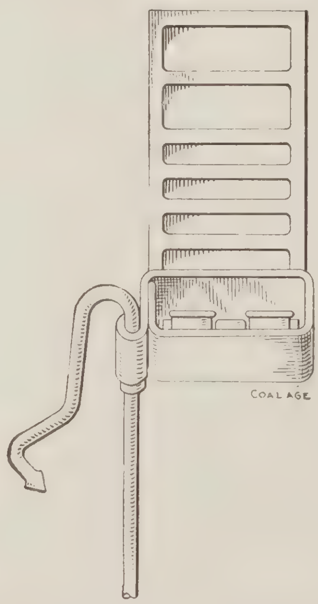
The general committee of the Colliery Managers' Association, according to the message of D. E. Parry to the members, are cordially approving everything which they believe will promote safety, and they propose communicating with the home secretary to secure redress in any matter which they consider will operate unfairly on managers as a class. In particular they propose to take steps to insure that a manager whose certificate is suspended for any reason should have the right to appeal, and they have also considered whether he should not have the right to continue to act as manager while that appeal is pending.

The divisional inspector of mines, Hugh Johnstone, although unable to discuss there any of the details of the Mines Bill, heartily congratulated the managers on the action they are taking. In an earlier bill, while the coal owners and workmen were strongly represented, when the bill was before the House of Commons, there was no such representative of the managers, because it was supposed their interests and those of the colliery owners were identical. Mr. Johnstone felt then that a great deal of responsibility was thrown upon the colliery manager, which would not have been placed upon him if he had been as ably represented in Parliament as the other interests.

A Simple Firedamp Detector

SPECIAL CORRESPONDENCE.

A very ingenious and novel firedamp detector which has been provisionally protected in Great Britain, is the invention of J. G. Guy, the resident manager of Wardley colliery in the county of Durham, and we are able to show its construction in the accompanying figure. The device consists of a sleeve with a combined divided screen, made from one piece of material, attached to the wick pricker of the safety lamp. The sleeve embraces the wick tube, and when moved upward the flame of the safety lamp is reduced to a mere speck without the slightest risk of losing the light, which usually happened by the ordinary method of drawing down the wick; the normal flame being quickly regained by drawing down the sleeve.



SHOWING DEVICE THAT MEASURES THE PERCENTAGE OF GAS

The divided screen well behind the flame, enables the "blue gas cap" to be easily measured, and the percentage of the gas present can therefore be estimated with facility. Reference to the illustration will give a clear idea of the invention without further description.

This ingenious contrivance has been seen and used by many of the leading mining engineers in Great Britain who speak highly of its simplicity, utility, and adaptability, and has been used by the inventor and his officials with the most satisfactory results. It is easily applied to any flat wick burner and is quite inexpensive. This simple and effective method of detecting firedamp must, in all cases where it is introduced, greatly increase the safety of working and tend to prevent disastrous explosions in coal mines.

Results of Experiments in France

Taffanel, the French expert, urges that the practice, frequently recommended, of watering in front of shot holes in dusty mine galleries, may be classed among the measures for preventing the initial ignition of the dust. Experiments have shown that the risks accruing from blownout shots are considerably lessened by this precaution.

As a general conclusion, Mr. Taffanel says: "Other conditions being equal, dry coal dust will be more dangerous in proportion as it is finer in grain. In galleries or working places where the dimensions of the finest particles are 1 to 2 mm., no coal-dust explosion can be produced by the more ordinary initiating causes, though an explosion can be propagated there as the result of a violent initial explosion occurring in a more favorable environment as regards dust, or started by firedamp or by the detonation of a store of explosives.

"Then again: Other conditions being equal, coal dust rich in volatile matters is more dangerous than if the content of the latter be small. No explosion can be produced by the ordinary initial causes in a dust deposit where the content of volatile matters does not exceed 18 per cent., though it may be propagated there as the result of a violent initial explosion occurring over a portion of dust deposit richer in volatile matters, or started by firedamp or by the detonation of a store of explosives. Coal-dust explosions developing, as the sequel of a powerful initial explosion, in a dust deposit unfavorable to propagation, are naturally less violent and more easy to arrest than those propagated in a favorable deposit."

Coal Production in Ohio

Ohio has produced more coal than any other State except Pennsylvania, Illinois and West Virginia. Since coal mining began in Ohio, in 1838, according to the United States Geological Survey, the State has produced 581,189,306 short tons, the figures showing an almost steady increase. In 1850 the production was 640,000 tons; in 1870 it was 2,527,285 tons; in 1890 it was 11,494,506 tons; in 1900 it was 18,988,150 tons; in 1905 it was 25,552,950 tons, and in 1910 it was 34,209,668 short tons.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of COAL AGE, we will print 6000 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

Testing the Fireboss

Attention is invited to the article on "The Appointment of Firebosses" appearing in this issue. Among the qualifications required are clearness of vision and good hearing.

As an instance of the vital importance of this subject, the disaster at the Globe colliery in England may be cited. This appears to have been directly due to the inability of a fireboss to detect 3 or 3½ per cent. of gas; at a subsequent test made by a government inspector, it was found that 31 out of 41 firebosses were incapable of detecting a like percentage.

The fireboss may be compared with the locomotive engineer, being directly responsible for such a large number of lives. As is well known, the engineers on our larger railroads are required to pass rigid eyesight tests, to insure their ability to distinguish the colors of lamps and brightly painted boards. On the other hand, the fireboss, often working under the most adverse conditions, and required to distinguish minute fluctuations of a hardly perceptible flame, is seldom subjected to any such test.

To the compilers of our State mine laws, is recommended the method of testing adopted by the government in British Columbia, whereby the exact percentage of gas the applicant is capable of detecting is accurately determined.

Safety in Mines

So much has been written on the subject of safety in mining that were it not for the grave importance of the question and the frequent misapplication of the term to some improved form of appliance or device, an apology would be due our readers. In some of its uses the word safety has become a misnomer, and has a tendency to deceive the unwary and confiding worker who must use the device.

Safety in coal mining means immunity from danger, accident, hurt or loss of any kind. A *safety* appliance is any device the proper use of which will lessen the danger of accident to man or machinery. Such are the safety lamps, safety gates, safety catches, safety blocks and a thousand other so called safeties.

To the general mind the word as here applied has a far greater significance than its use in this connection warrants. A safety lamp is only safe, in the presence of gas, when it is in perfect condition and properly handled by a competent person and not subjected to conditions beyond its power of resistance. Under other conditions than these a safety lamp is not only *unsafe* but positively dangerous.

Likewise, safety gates that are too frail or insecure in their attachments, or safety catches on cages that would fail to operate in time of need are a menace to safety, because they inspire a false feeling of security. A full knowledge of a present danger is the surest safeguard, because such knowledge suggests at once the remedy or at least admonishes caution. Automatic devices that tend to diminish the vigilance, the care or the caution of the person or persons in charge of life and property, invite danger and increase the risks of operation instead of diminishing them.

Many mine managers and superintendents have rejected and refused to install overwinding devices at the mines in their charge, because of their firm conviction that such a device installed at a hoisting shaft tends to make, and in most cases does make, the hoisting engineer less watchful, cautious and on his guard. The apparatus appears to work so perfectly that the engineer comes at length to rely wholly upon its operation, and himself becomes an automaton; till suddenly some sad day the spell is broken by the failure of a single part of the mechanism, and the inevitable happens. It is all done in a twinkling, but the results of that moment's unguardedness on the part of that engineer are fatal to the lifetime happiness and comfort of the widows and fatherless, made such by the accident.

Some years ago, a mine-signaling system was suggested by an engineer of standing, by which it was hoped to be able to indicate in the mine office on the surface, the gaseous condition of the mine workings whenever such condition became dangerous. The impracticability of the scheme was discussed by mining men everywhere and the effort to install the system in mines was defeated and finally abandoned. Recently, another attempt has been made to patent a somewhat similar system for the detection of dangerous quantities of explosive gas in the mine chambers, and giving the alarm at the surface. Such systems have for their ultimate tendency the elimination, in whole or in part, of the work of the fireboss or mine examiner.

All like attempts to eliminate the human factor by replacing human consciousness with an automatic mechanical device, however ingenious, jeopardize the safety of the mine just to the degree that official care and watchfulness are decreased. There is no question but that there are many helpful and desirable automatic devices adopted and in use at many mines. Our remarks refer only to such devices as are designed to transfer the responsibility for the safe operation of mines from the certified officials to the uncertain operation of a machine, which might result in finding no one responsible for loss of lives when, in truth, the responsibility should rest on the mismanagement shown in the adoption of such device.

The adoption of different forms of automatic mine doors, in order to cut out the expense of trappers, has resulted in the accidental death of many drivers and the loss of many valuable mules. The failure of the device to work, in such a case, leaves but a meager chance for the escape of either the driver or the mule, especially if the door is located on a slight grade or at the foot of a grade, which should never be done.

Our desire in this brief article is to draw the attention of mine managers and superintendents to the importance of so regulating every operation, in and about the mine, as to fix, beyond doubt or question, the responsibility for accidents that may be foreseen as possible and liable to occur through lack of faithful and thorough inspection. The duties of each official should be clearly defined and his instructions so given that the responsibility for any ordinary accident cannot be shifted.

We would further impress upon miners the fact that any so called *safety* appliance to be *safe* must be properly used. The term safety does not mean exempt from danger. The fact that a safety appliance is necessary at all should warn all persons of the danger to be avoided, and should urge upon every mine employee the need of caution.

Corrosion by Mine Water

Acid mine waters eat freely into bodies of concrete exposed to them, especially if the concrete is mixed stiff. When mixed with an excess of water, the necessary reactions in the cement appear to take place, resulting in a concrete which has more power to resist sulphuric acid. This acid combines with the earthy elements, such as calcium, setting the silicic acid free. The severity of action on stiff mixed concrete seems to be diminished with time. The portal of the Hoffman tunnel near Frostburg, Md., through which much mine water passes, was eaten into below the water line, nearly two inches in the first two years. After that time no further ill resulted. And in the Georges Creek field, it has been found that concrete mixed with excess of water, always shows considerable resistance to corrosion.

In the anthracite field, marked instances are to be found of the corrosion of concrete, which was mixed so wet that the water rose to the tamped surface. It must be remembered that the waters of the anthracite field are often unneutralized by the action of natural limestones, and though harmless in appearance, are nevertheless incredibly active. A concrete breaker, erected in 1905, shows much corrosion, as does also a concrete tank in which sulphur water is stored.

The most harmful effect is to be found in the uncovering of reinforcement. The tension face of a beam should always be carefully protected, where corrosive action is feared. It has been shown in a large number of experiments that no reliance can be placed in the tensile strength of the concrete alone and that as soon as strained to its point of endurance it cracks, in fine hair-like crevices, invisible to the eye, except where aided by the presence of water, in which case the cracks are clearly lined out. When a beam is loaded therefore, so that the tensile deformation exceeds that which the concrete can endure, cracking must take place, even though the reinforcement may carry loads many times as great as those imposed. Thus a safe beam may be so creviced that corrosive waters have a good chance to work on the strengthening rods and that chance is enhanced when the covering they receive is but slight. This leads to the suggestion that the iron in ferro-concrete should be placed further within the whole mass, additional concrete being used to secure this result, wherever corrosive waters are to be encountered, as, for instance, in the washing department of a breaker.

It might be argued that concrete being porous, corrosive waters will penetrate whether the integrity of the concrete is or is not destroyed by strain. But it is more than probable that the virulence of the waters is neutralized by the outer layers of concrete and that glassy impervious silica is deposited on the outside, preventing further decomposition. The whole question of corrosion due to the action of mine water is one that the U. S. Bureau of Mines might well subject to experiment.

Government Appropriations

During the last 20 years, the Government has appropriated amounts varying from 20 to 40 million dollars per annum for the Department of Agriculture. While we do not begrudge this department its generous appropriation, and appreciate that it has been the means of accomplishing enormous results, we do feel the amount, as compared with that alloted the mining industry, is entirely out of proportion.

The appropriations to the Department of Agriculture are for commercial purposes, while an appropriation to the Bureau of Mines means increased efficiency not only in the conservation of natural (and exhaustible) resources, but to *human life*. We do not believe that commercial problems are due a greater consideration than is given to the protection of our workmen.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

Slabbing or "taking up a skip" should be strictly forbidden as it often results in a loss of coal as high as 50 per cent., besides calling for an excessive use of timber. It also results in dirty coal and is dangerous and expensive.

Tests have shown that some weathered lignites make excellent briquets. The future may see lignite slack take its place beside bituminous slack and anthracite screenings as a material for the manufacture of briquets on a commercial scale.

In tests made at the mining-experiment station at Pittsburg, bituminous-coal dust through a 200-mesh sieve floated on a strong current of air, and caused an explosion when there was only 0.032 oz. of it per cubic foot of air, or one pound per 500 cu.ft. of air.

When robbing pillars see that each fall is of sufficient size, the cars removed and the timbers drawn before the strata loosen, as this lightens the weight on the next pillar. This method prevents excessive weight on pillars, increases the safety of the workmen and tends to give a high percentage of recovery.

The successful robbing of pillars depends to a large extent upon the mine boss. He should make a careful daily inspection of all pillars and should be present himself or send an assistant when falls are made, so as to be able to decide upon the amount of coal that can be taken out without danger from the overlying strata.

The yield per foot acre of anthracite coal was recently determined by Judge Newcomb, of Lackawanna county, Pennsylvania, in a case of the Delaware, Lackawanna & Western Railroad Company versus the County Commissioners. The subject was in dispute for some time, but it was finally decided that the yield per foot acre is 1225 tons.

Ventilation has much to do with determining the life of mine timbers. Poorly ventilated, moist, air passages and gangways are always productive of decaying timbering. In such cases preservation treatment gives good results, though it in no way benefits timber subjected to wear, such as drum lagging, wooden rollers, etc.

When a new hoisting rope is purchased the maker should be required to furnish a certificate of test, both of the wire used and a sample length of the finished rope. The tests should be of as comprehensive character as possible, embracing tensile, torsional bending and fatigue tests. All the details should be freely set forth in the certificate.

Uniform mining laws, as far as local conditions permit, throughout the coal-mining States of the union, would do much to add to the safety of the occupation. The miners are constantly moving from one camp to another, and from State to State, and the wrong methods of one State are easily and quickly introduced into another State. Uniform laws would do much to overcome this spread of unsafe practices.

When crushing coal for briquetting purposes be careful not to get it too fine or additional binder will be necessary. It will also be harder to fire although making a better appearance in the market because it will have a smoother surface and will not weather easily. See that the coal is not crushed to a uniform size or much more binder will have to be used. About 56 per cent. of the material used should consist of grains ¼ in. in diameter.

When possible all mine employees should be instructed as to the danger, prevention, cause and the most effective method of fighting mine fires. Mine managers should see that all possible means are adopted to control the strong drafts often found in shafts, entries and haulage roads as they are a source of great danger in case of fire. Foremen should be drilled in withdrawing the men from the mines, and the individual miner should receive instruction on the subject.

The disadvantages of dump storage for anthracite coal are; excessive breakage; the impracticability of rescreening, and high cost of operation, which amounts to 20 to 25c. per ton. Such storage should be considered as suitable for steam sizes only. Trestle storage should never be used if it possibly can be avoided, as it gives a high percentage of breakage, is costly to maintain, has a relatively small capacity, and rescreening is difficult. It should never be found outside of yards doing a small retail business.

A good storage plant should be capable of screening all coal before shipment, preparing all screenings for sale or briquetting, handling frozen coal by means of hot water and have an ample drainage system; storing all sizes in bins or spaces by themselves; and rapidly handling any and all the sizes. Such plants should also be so located that enlargement can be made as necessity demands. The first cost per ton of capacity should be low. The trackage through the plant should be more than sufficient to handle the expected tonnage and minimum breakage in stocking and reloading should be the motto of all such plants.

A single-stroke style of signal bell is preferable to the trembler style as it is more easily heard. Distinctness is the first and greatest requirement of a signal system. Much of the efficiency of a signal depends upon the quality of the equipment and the perfection of installation. All wires should be incased in wooden casings if the mine is dry or in iron piping in the case of wet mines. In deep shafts a junction box should be located near the middle of the shaft to facilitate the localizing of defects in the wire and help in its support. Wire used in a shaft should be insulated with lead covering and incased in smooth piping to protect it from injury. Only dust, gas and damp proof bells should be used in gaseous mines, for an ordinary bell is exceedingly dangerous in a gaseous atmosphere.

The burning qualities of briquets, the flame produced, the smoke given off and the completeness of combustion depend largely upon the shape of the briquet and the nature of the binder used. Briquets should be of such shape as to insure a good circulation of air. The binder should not contain too high a percentage of constituents having a low boiling point or it will distil away before the briquet is heated to ignition and give off the smoke and odor which should be absent from the burning of the perfect briquet. Inorganic binders and also starch, molasses and sulphite liquor are smokeless. Tar pitch and petroleum residues, if not carefully regulated, will produce smoke and odor, but if the shape of the briquet is such as to allow a good circulation of air through the bed of fuel, thus enabling a more nearly complete combustion to take place, the smoke given off will be less than that produced by the coal from which the screenings were derived.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Effect of Regulators in Splitting

A total of 8000 cu.ft. of air is passing through three airways *A*, *B* and *C*, with a water gage of 1.7 in. All areas are the same; but the lengths of the airways are: *A*, 6000 ft.; *B*, 10,000 ft., and *C*, 21,000 ft. It is desired to increase the quantities in *B* and *C* so as to make each of the three airways pass an equal quantity of air. (a) What effect will it have on the water gage? (b) In what proportion will the resistance be increased in *A* and *B* when the change is made? (c) If *B* and *C* each get as much air as *A* gets now, what will be the total increased circulation?

Puritan, Penn. H. M. M.

Power on air before change is made

$$Q\,p = 8000\,(1.7 \times 5.2) = 70{,}720 \textit{ ft.-lb. per min.}$$

Natural division of air, before change: Assuming that each split has the same cross-section, the perimeter (o) and area (a) are constant for all the splits, and, since the pressure is the same in each case, the quantity of air passing in each airway is inversely proportional to the square root of the length of the airway. The relative lengths 6, 10, 21 can be used in this calculation; thus,

$$\left.\begin{array}{ll} \text{Split } A,\ 6{,}000 \text{ ft.}, & \dfrac{1}{\sqrt{6}} = 0.4082 \\ \text{Split } B,\ 10{,}000 \text{ ft.}, & \dfrac{1}{\sqrt{10}} = 0.3162 \\ \text{Split } C,\ 21{,}000 \text{ ft.}, & \dfrac{1}{\sqrt{21}} = 0.2182 \end{array}\right\} \text{relative potentials}$$

$$\text{Sum of potentials } 0.9426$$

$$\left.\begin{array}{ll} A, & \dfrac{0.4082}{0.9426} \times 8000 = 3464 \\ B, & \dfrac{0.3162}{0.9426} \times 8000 = 2684 \\ C, & \dfrac{0.2182}{0.9426} \times 8000 = 1852 \end{array}\right\} \text{cu.ft. per min.}$$

$$\text{Total quantity } 8000$$

Assuming the power on the air remains constant, it is proposed to place regulators in splits *A* and *B* so as to equalize the air in all the splits; and the question asks what effect this will have on the water gage. It is necessary, first, to find the total quantity of air that the same power will pass in these three splits after the regulators are placed in *A* and *B*.

Since the quantity and the pressure are to be the same in each split after the regulators are in place, the power ($Q\,p$) will be equal in each split; or $70{,}720 \div 3 = 23{,}573$ ft.-lb. per min. Now, as there is no regulator in the open split (split *C*), the quantity of air passing in this split is proportional to the cube root of the power on the air. In other words, the quantity ratio is equal to the cube root of the power ratio; thus, calling x the new quantity passing in split *C*,

$$\frac{x}{1852} = \sqrt[3]{\frac{23{,}573}{1852\,(1.7 \times 5.2)}} = 1.129 +$$

$$x = 1852 \times 1.129 = 2090 + \textit{ cu.ft. per min.}$$

(a) Since for any open split the pressure or water gage varies as the square of the quantity of air passing, the water-gage ratio is equal to the square of the quantity ratio. Then calling the required water gage after the change x,

$$\frac{x}{1.7} = 1.129^2 = 1.275 +$$

$$x = 1.7 \times 1.275 = 2.16 + \textit{ inches.}$$

(b) Since the sectional area (a) is not changed, the resistance ($p\,a$) in *A* and *B*, and in fact throughout the mine, will be increased in the same ratio as the pressure or water gage, or as

$$\frac{2.16}{1.7} = 1.27 \textit{ times.}$$

(c) The total quantity of air circulating in the mine would be, in this case, $3 \times 3464 = 10{,}392$ cu.ft. per minute.

Timber Framing for Side Pressures

We are having a lot of trouble with our timbering because of the softness of the coal, which throws all the weight against the sides of the posts. The roof is a

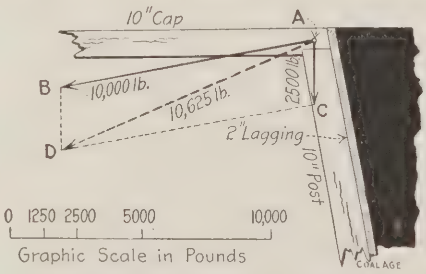

DIAGRAM OF FORCES IN A TIMER SET

hard, sandy shale which seldom breaks, but settles hard on the pillars, squeezing them out against the posts. We use 2-in. lagging on the sides and 10-in. caps and posts.

We do not know what the pressures are, but think the side pressure is about four times that on the caps. In order to make the joint of the cap and post right, we would like to know the resulting direction of two pressures acting this way.

TIMBER FOREMAN.

The condition is not an unusual one in coal mines and the problem may be readily solved graphically. To fulfil the prescribed conditions a side pressure of 10,000 lb. on the posts and a vertical load of 2500 lb. on the cap will be taken, and it will be assumed that these loads act at the joint of the cap and post.

Draw the center lines of the post and cap, and at their intersection *A*, Fig. 1, draw *A B* perpendicular to the center line of the post. Make this equal to 10,000 lb. according to the graphic scale. Draw *A C* perpendicular to the center line of the cap, making it equal to 2500 lb. Now complete the parallelogram by drawing *C D* parallel to *A B*, and *B D* parallel to *A C*, and to the intersection *D*, draw *A D*, the resultant. *A D* shows the direction of the resultant of the two forces acting on the cap and post, and by scaling the length we find it equal to 10,695 pounds.

As will be noted, this resultant lies close to the roof and it would be interesting to hear from our correspondent, and others, as to the best method of framing timbers under these conditions.

Which Is Better, Fuse or Squibs

I have long been accustomed to use a good quality of double-tape fuse, in blasting coal, but am told that it is much safer to use a squib. Kindly give me your opinion, as I think a good coal paper should explain this matter thoroughly.

A MINE FOREMAN.

Our correspondent will find the use of fuse and squibs in blasting coal quite fully explained on page 131 of COAL AGE, Nov. 4, under the headings, "Safety in Blasting in Mines," and "Hangfires in Blasting with Fuse." We would simply add here, *never* use fuse when a good safety squib can be procured. The reasons why the use of squibs is safer than that of fuse are the following:

Squibs are less liable to injury, or to contain imperfections that would cause the shot to misfire, or at least to hang fire for an indefinite period of time. A good squib, properly used, is more positive and reliable in its action, less subject, in its use, to the dampness of the mine, and permits the hole to be tamped quicker and better than fuse. Squibs are cheaper than fuse. They do not permit an unscrupulous miner to overcharge his hole and escape the possible chances of trouble, which he can often do, to the jeopardy of his fellows, when fuse is allowed.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Handling Mine Cars in Pitching Seams

In anthracite mining, owing to the nature of the formation, the seams or "veins" of coal, as they are commonly called in Pennsylvania, are more or less highly inclined. The steep inclination of the haulage slopes or the roads in the chambers, makes the handling of the mine cars dangerous and calls for special and careful consideration in order to avoid, as far as possible, the accidents that occur so frequently, in this regard.

The mine foreman in a pitching seam is constantly confronted with the question of what will be a safe grade in an entry where mule haulage is employed; or, in what direction should the chambers be driven with respect to the pitch of the seam in order that the cars may be safely handled by the miner in his room. As the pitch of the seam increases, the chambers are often driven at a greater or less angle with the strike of the seam or the gangway, so as to reduce the grade of the roads in the chambers. When, however, it is impossible by this means to obtain a safe grade for handling cars in the chambers, the mine foreman must decide what means can be adopted to lower the cars more safely from the face of the chamber to the gangway. These are interesting questions, that are more easily solved when we understand a few of the principles involved. Some of these principles will be briefly explained in the following:

First Principle—Cars Moved by Gravity—Gravity Pull

The force of gravity acts vertically downward. This force acting on the car gives it weight. When the car stands on a level track, see Fig. 1, the weight of the car acts in a direction perpendicular to the track, and is wholly balanced by the resistance of the rails. There is, in this case, evidently, no force acting to move the car along the rails.

When the car is on an incline, see Fig. 2, the weight of the car OW still acts vertically downward, but is not now perpendicular to the track. In this case, the weight OW is resolved into two forces; one OP parallel to the track, and the other ON perpendicular to the same. The force OP acts to move the car along the rails and is the *gravity pull;* ON is the *normal pressure* of the car on the rails, and is wholly balanced by the resistance of the rails.

From the construction of the figure, angle $PWO =$ angle $WON =$ angle of inclination of road CAB;

$$OP = OW \sin PWO;$$

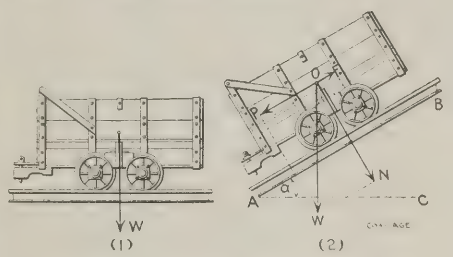
$$ON = OW \cos WON.$$

Rule—On any inclined plane or road the gravity pull equals the weight of the car multiplied by the sine of the angle of inclination of the road. Normal pressure on rails equals the weight of the car multiplied by the cosine of the angle of inclination of the road.

Example—What is the gravity pull of a loaded car weighing 3 tons, on an incline when the angle of inclination is 30 degrees; and what is the normal pressure of the car on the track?

Solution—The weight of the car is $3 \times 2000 = 6000$ pounds.

Gravity pull, $6000 \times \sin 30 \text{ deg.} = 6000 \times 0.5 = 3000$ pounds.



Showing Forces Acting on Car

Normal pressure on rails, $6000 \times \cos 30 \text{ deg.} = 6000 \times 0.866 = 5196$ pounds.

Second Principle—Movement of Car Resisted by Friction—Friction Pull

When starting a car there is always a certain resistance due to the inertia of the car and adhesiveness of the moving parts that may be considerable. This starting friction cannot be estimated accurately, as it varies greatly. It may be several times the actual rolling friction when the car is in motion.

What may be called, for our purpose, the *rolling friction*, however, is more uniform. It may be estimated closely as a fraction of the normal pressure of the car on the rails. If the track or road is level, or has only a slight inclination, the frictional resistance or *friction pull* is a fraction of the weight of the car. On an incline, however, to be accurate, this must be multiplied by the cosine of the angle of inclination of the road.

The friction pull always acts parallel to the track and in a direction opposite to that in which the car is moving; it is represented by OF in Fig. 2. The ratio of the friction pull to the weight of the car or the normal pressure on the rails, as the case may be, is called the coefficient of friction. In mining practice, the coefficient of friction may vary according to the condition of the rails and wheels from $\frac{1}{50}$ to $\frac{1}{25}$; or, expressed decimally, 0.02 to 0.04. Calling this coefficient c, we may assume for an average value, under ordinary conditions of mine-haulage roads, c equals 0.025, making the friction pull $\frac{1}{40}$ of the weight of the moving load or the normal pressure on the rails, as the case may be.

Friction pull, level road,

$$OF = c \times OW.$$

Friction pull, inclined road,

$$OF = c \times ON = c \times OW \cos a,$$

in which a is the angle of inclination of the road.

Example—What would be the friction pull, in ordinary mining practice, of the 3-ton loaded car mentioned in the previous example, (a) on a level haulage road, (b) on a haulage slope having an inclination of 30 degrees?

Solution—Assuming the coefficient of friction as $c = 0.025$,

(a) Friction pull, level road,

$F = 0.025 \times 3\ (2000) = 150$ *pounds.*

(b) Friction pull, 30-deg. slope road,

$F = 0.025 \times 6000 \times \sin 30$ *degrees.*

$F = 0.025 \times 6000 \times 0.5 = 75$ *pounds.*

Note—(1) On an incline, the friction pull is always less than on a level road, for the same load. For the same load, the friction pull decreases as the angle of inclination increases, but not in the same proportion. In a vertical shaft, the friction pull is practically zero. (2) On a level road, the friction pull is equal to the drawbar pull; but on an incline, the drawbar pull of an ascending car or trip is equal to the sum of the gravity pull and the friction pull.

Example—Assuming the same value for the coefficient of friction as before, what is the drawbar pull of the 3-ton loaded car mentioned in the two previous examples, (a) on a level road, (b) on a slope of 30 degrees?

Solution—(a) Drawbar pull, level road,

$P = F = 150$ *pounds.*

(b) Drawbar pull (30-deg. slope),

$P = 3000 + 75 = 3075$ *pounds.*

Note—On a level road, or a slope road, the drawbar pull is always the pull on the haulage rope. It should be carefully noted, however, that when cars are being lowered on an incline, engine plane or gravity road, the load on the rope is

equal to the gravity pull less the friction pull; because, in this case, the cars are moving down the incline, while, in the example given above, the car was being hauled up the slope. When hoisting the friction pull acts in the same direction as the gravity pull, but when lowering the cars, the friction pull acts in the opposite direction to the gravity pull.

From the Ranks

A Fireboss' Suggestion

As I have had a good deal of experience in firebossing in mines in the Pittsburg district, I want to write a few lines and hope you will publish them in your paper as I am a subscriber and reader of COAL AGE.

A fireboss is a man who must get out of his bed, in the dead hour of night, whatever the weather may be, and proceed to examine the mine or district in his charge. It is dangerous work, and must be done and the mine reported safe before the men are allowed to enter for the day's work.

When an explosion occurs, as it will at times, and the fireboss is killed, many say it was because he did not do his duty properly. Those who are so quick to lay the blame on the poor fireboss do not understand the peculiar conditions under which he is obliged to work. He must obey the law or he is liable to be arrested and prosecuted by the mine inspector. Also, he must do what the company wants or he will be discharged. In many cases the company wants to get along without doing all the law requires.

There are many firebosses who are afraid they will lose their jobs, and are willing to do anything that the mine foreman or superintendent asks, and run the risk of accident and the consequences of the mine law. Some of these men are personal friends of the officials, and work to suit them without regard to the law, or their own individual responsibility under the law.

The mine law (bituminous, 1911), Article 5, Section 6, makes the fireboss responsible for a "false report" of the condition of any place or portion of a mine allotted to him for examination; and for such "misdemeanor," makes it the duty of the mine foreman to suspend him and report his name to the mine inspector for prosecution. This act virtually shifts the responsibility for the security of the mine and the safety of the men from the fireboss to the mine foreman; for what mine foreman, having gotten his firebosses to disregard the condition of any section of the mine and admit the men for work, will report the matter to the inspector, *unless an accident results; and then the whole blame rests with the fireboss who sold himself to make "a false report."* Can a worse condition be imagined than to be obliged to work thus, when any day the fear of the loss of his place will induce an honest fireboss to do violence to his conscience and run the risk of bringing disgrace upon himself and his family?

I never wrote to a magazine before, but do so now to make one suggestion. It is this: For the safety of the men and property concerned, the fireboss should be a government officer, appointed under the government and commissioned by the same for the daily examination of the mine, under the supervision and control of the district mine inspector. The fireboss would then be able to perform his duties, in the inspection of the mine, without fear or favor, and the three-cornered condition that now exists between the mine inspector, mine management and the fireboss would be at an end.

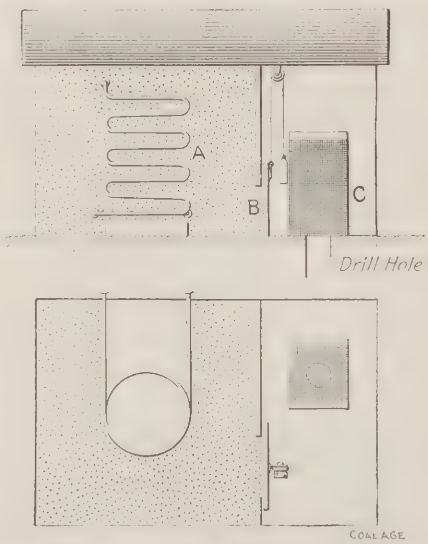
Sand House to Supply Mine Motors

The accompanying cut shows the arrangement of a sand house, or sand box, for supplying sand direct to the mine for the use of the mine motors. It consists



SAND HOUSE TO SUPPLY SAND TO MINE MOTORS

of a wooden box, or a small frame building or shed can be built, if desired, on the surface, immediately over a 4- or 6-in. drill hole that is sunk from the surface to a point in the mine most convenient for supplying sand to the motors.

The sand is delivered by cars or wagons, and unloaded into the box at *A*. In this portion of the box there is a steam coil arranged to dry the sand. As sand is required in the mine it is shoveled from the trap-door marked *B* onto the sieve *C* which screens out all coarse stones, gravel and sticks, and thus prepares the sand for use in the motors. The screen *C* stands immediately over the drill hole through which the sand falls into the mine. This arrangement has proved a considerable benefit in the saving it has effected in the cost of handling sand. The cost of handling the sand before this arrangement was instituted was $1 per day. By the present arrangement it takes just 30 minutes to get the sand down into the mine, at a cost of 15 cents per day.

Inclined Plane Haulage

In reading your issue of Oct. 21, I notice in the description of the Castle Valley Coal Company's plant, at Price, Utah, the writer gives the manufacturers of the different classes of machinery installed, but has inadvertently omitted to state that the inclined-plane haulage at this plant, which is one of the largest planes installed under the most severe conditions, is equipped with our machinery. I know you will gladly give me space in your valuable paper to make this statement.

S. B. STINE.

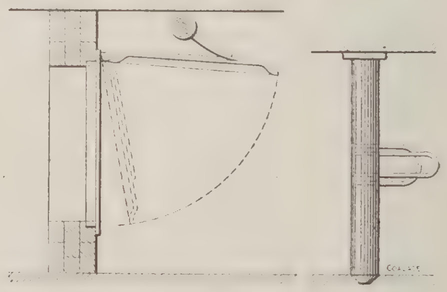
A Simple Device for Closing Air Doors

The device shown in the accompanying sketch, is successfully used in some German mines. Two short lengths of wire rope are bent, each in the form of the letter U and fastened, one outside the other, into holes drilled for the purpose



ROPE LOOPS FOR CLOSING AIR DOORS

in a mine prop. The rope is secured in these holes by means of wooden wedges. When the door opens against the loops, the elasticity of the rope is sufficient to act as a spring and close the door. With wooden doors the loops are best fastened to the frame of the door itself.

Experience has shown that whenever practicable, triangulation gives the best results in surveys for the development of large coal properties.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Glen Jean, W. Va., Examination

Selected Fireboss Questions

Ques.—What would you do in the event of an explosion that had destroyed your ventilation, in order to rescue the living and recover the bodies of the dead? Explain fully and in detail.

Ans.—Much will depend on conditions not stated in the question. If both shafts are belching smoke, dust and gas, and there is no other entrance to the mine available, it would not be wise to attempt to enter, for a time at least, even with breathing or rescue apparatus. Start at once to repair the fan or to install a temporary ventilator. After a time one or the other of the two openings will show signs of downcasting. Advantage should be taken of this, and as soon as possible the ventilator should be connected and run as an exhaust or blower so as to assist the natural tendency of the circulation as shown by the discharge from the shafts.

In the meantime every effort has been made to organize and equip two rescue parties under the leadership of experienced men acquainted with the mine. Descent into the shaft with the rescue apparatus is made at the first opportunity that promises a reasonable degree of safety, in order to ascertain the condition below and if possible assist the air-current by the removal of any obstruction blown into the airway; or extinguish smouldering fires that only need fresh air to burst into flame. The work is extremely dangerous and requires the cool, experienced action of brave men, whose judgment will be their greatest safeguard. As soon as practicable, the air-current having been started, the other rescuers follow; the men equipped with breathing apparatus and electric lamps going ahead, and the others following with safety lamps as fast as the air-current can be established. No advance must be made by these men ahead of the current.

Ques.—What instruments are used to properly determine the condition, volume and temperature of the air-current in a mine? State fully the principle and application of each.

Ans.—The safety lamp, hygrometer, anemometer, watch and measuring tape, and the thermometer. The safety lamp depends on the cooling effect of the wire gauze surrounding the flame or protecting the openings of the lamp. The cool metal of the gauze extinguishes any flame that would otherwise pass through the mesh. The mixture of gas and air enters through openings and burns freely in the lamp; but the flame of the burning gas cannot pass out to ignite the gas outside the lamp, unless the gauze is defective or becomes heated, or the lamp is improperly handled.

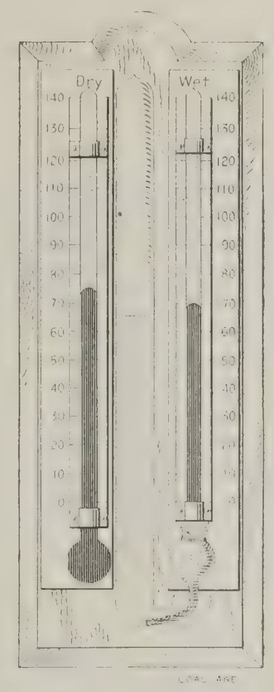

Fig. 1. The Hygrometer

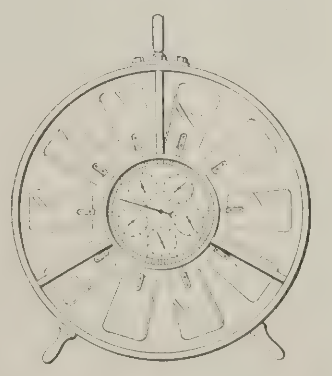

Fig. 2. The Anemometer

The hygrometer, sometimes called the psychrometer, consists of two standard thermometers mounted on a frame, as shown in Fig. 1. The bulb of one of these thermometers is kept wet by a sack of muslin, which is tied over it and which terminates in a wick that dips into a water bath below. The evaporation of water from the sack covering the bulb lowers its temperature; so that the reading of the wet-bulb thermometer is lower than that of the dry-bulb thermometer. The difference of the two readings indicates the degree of saturation of the air. When the air is fully saturated no evaporation takes place and the readings of the two thermometers are the same.

The anemometer (Fig. 2) is a vane set in a metal frame and connected by a series of gears with the hands on a registering dial. The blades of the vane are inclined at such an angle that one revolution of the vane corresponds to one lineal foot of air-travel. The dial registers the number of revolutions of the vane and therefore the distance the air travels in the time the instrument is exposed to the current. This time is noted by the watch. The velocity of the air-current, in feet per minute, is thus determined. The sectional area of the airway where the observation is taken is measured with the tape and this area, in square feet, multiplied by the velocity of the air, gives the air volume, in cubic feet per minute.

The temperature of the mine air is made known by the reading of the dry-bulb thermometer.

Safety and Efficiency of Boilers.

Ques.—What are the principal boiler fittings designed to increase the safety and efficiency of the operation of boilers? Explain briefly the purpose of each.

Ans.—The safety valve, water-gage, gage-cocks or try-cocks, steam gage, fusible plugs, mud-drum, blowoff valves and feed-water heater. The safety valve is a valve generally attached to the steam dome of the boiler to automatically relieve the steam pressure in case the latter rises above a certain point; the steam gage is to indicate the pressure of the steam in the boiler. The water-gage and gage-cock or try-cock are to indicate the level of the water in the boiler, while the fusible plugs, by melting when the water level falls below a certain fixed point, give warning by the escape of the steam into the firebox. The mud-drum is for the purpose of collecting the sediment that accumulates in the boiler, while the blowoff valve is used in cleaning the boiler by blowing out a portion of the water, under pressure. The feed-water heater is used to heat the water before it enters the boiler, which results in a large saving of fuel and in many cases, also, helps to purify the water.

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

Liquor Problem in Mining Communities

By C. L. Fay*

While considering the fact of a liquor problem in mining communities it is instructive and interesting to note the sentiments of captains of the coal-mining industry.

A general manager of one of the largest anthracite companies said recently, "We know there are entirely too many saloons and that the use of liquor seriously affects not only the operation of the mines but also the welfare of the men and their families. If I had my way, there would not be a place to sell liquor or any way of getting it within 100 miles of any of our operations. I can see no good whatever in the saloon.

"It is said that the men need a place to visit for recreation and for social purposes. The base-ball field, Y. M. C. A. rooms, pool and billiard rooms without the liquor attachment, and the garden, will give a man all the recreation he requires. If he wants to meet good people, he can go to church and Sunday school or a lodge of one of the many reputable organizations."

Another Personal View

The president of one of the largest bituminous coal operations in Pennsylvania and West Virginia says: "I think the best thing would be to eliminate or prevent the manufacture of liquors.

"As long as liquors are made and permitted to be shipped into a community, I think that a licensed saloon properly conducted is the best regulator of the traffic.

"I find that when no saloons are near our mines, the employees bring in whisky by jug and beer by the keg or barrel, and often have orgies that last for a week at a time, but I find that where saloons are properly conducted, the miners go in and get a glass of whiskey or beer and then go about their business, thus preventing these orgies that occur where the men buy by the barrel, keg and jug."

Very good. There is truth and logic in both views, but let us place the average mining-town situation alongside the statements.

In the first place, the average mining town does not possess a Y. M. C. A. building and equipment. Too often the gardens are backyards of mud and rocks and too small to be converted into plots that will "produce."

The fields are side hills strewn with boulders or covered with scrub oak or other bushes, while the "flats" are masses of culm. Pool and billiard rooms without liquor "available" are somewhat of a myth and at best are permeated by an immoral influence that is as vicious as liquor is detrimental.

The Saloon Fails to Regulate Liquor Traffic

Experience has demonstrated that the saloon is a failure as a regulator of the liquor traffic, at least under the operation of existing laws.

In the best equipped mines, there will be a maximum of loss in operation, unless back of that equipment, the human factor is ever vigilant and persevering.

The same thing applies to the liquor and social-welfare problems in the mining community. No matter how excellent the methods, or how suitable the equipment to attract men and divert their thought and energies from dissipating habits, the endeavors will fail unless the coal-company officials constantly exert the same efforts to get maximum efficiency from the social-welfare equipment, that they employ to get the highest efficiency from mine equipment. An industrial corporation will secure the best results, when utilizing or coöperating with various welfare movements, by insisting upon a definite working relationship.

The liquor problem is an economic one in the matter of operating mines, and until the coal companies fully recognize the fact that it must be dealt with in a business way as any other business problem, the average mine will continue to operate at a loss in tonnage of 5, 10 and 15 per cent. every month.

I will conclude this series of articles next week with a description of the Greenwald Welfare Committee as promoted by the Donahoe Coke Company at Crabtree, Pennsylvania.

*Secretary, Coal Mining Institute of America, Wilkes-Barre, Penn.

Note—This is the fourth article discussing the above subject.

The Pancoast Relief Fund

The beneficiaries of the Pancoast disaster relief fund received their first payment Wednesday, Nov. 9, at the Anthracite Trust Company's banking rooms in the Mears building, Scranton, Penn.

The relief committee furnished to the trust company the amounts each beneficiary was to receive, and the trust company adopted the following plan of identification and disbursement:

A photographer went the rounds taking a picture of each one entitled to payment. The beneficiary had to be properly identified before the picture was taken.

Each beneficiary's picture was pasted upon the ledger page of his or her account, and when he or she came for the money, the picture spoke for itself.

The relief committee does not issue checks or warrants. It simply supplied the trust company with an official list of the payments to be made, and the trust company drew its check for each individual payment.

Scranton Mining Institute Banquet

The third anual banquet of the Scranton District Mining Institute, held in Scranton, Penn., on Oct. 21, was attended by over 1600 men, representing every phase of the coal-mining industry from driver boys to general superintendents and presidents of companies.

Addresses were made by Judge H. M. Edwards, toastmaster; C. E. Tobey, president of the Institute; Major Everett Warren; William H. Truesdale, president of the Delaware, Lackawanna & Western railroad, and others. Mr. Truesdale congratulated the association on its growth and on this remarkable meeting which he found interesting, instructive and inspiring, and went on to point out that from operators and managers down to the humblest mine worker, all were comrades in prosecuting a great industry.

Mr. Tobey gave a short history of the Institute from its organization in 1908, to the present time, dwelling particularly on its wonderful growth in the past year from a membership of 142 to a total of 1756.

The Raleigh Mining Institute

On Wednesday night, Oct. 25, a banquet was given by the Raleigh Mining Institute in the new R. M. I. building, at Raleigh, W. Va. This institute was organized in October, 1908, for the purpose of studying practical and scientific methods of operating coal mines, in order to better fit the officers and employees of the Raleigh Coal and Coke Company, to perform their duties and assume the responsibilities thrust upon them, for the betterment of conditions, more efficient mine management and the preservation of life and property.

The institute began with a membership of 12 persons. Today the Raleigh Mining Institute has a membership of 38, composed of the managing officials and the foremen of the Raleigh Coal and Coke Company, and Lance B. Holliday, inspector of the 9th district, West Virginia Bureau of Mines.

On the night of the banquet, this organization met in regular session and was called to order by President James P. White, general superintendent of the Raleigh Coal and Coke Company. The institute proceeded to elect Ernest Chilson, general manager of the Raleigh Coal and Coke Company, toastmaster, to preside over the banquet. The applications for membership of J. W. Heron, chairman Chesapeake & Ohio railway allotment commission; James Clark and D. R. Phillips, his associate commissioners; Prof. E. W. McDairmaid, of Beckley Institute; George W. Stevens, Jr., youngest son of President George W. Stevens, of the Chesapeake & Ohio Railway Company; A. F. Beck, general manager of the Charleston Electrical Supply Company, and Professor J. A. Thompson, of Glenleigh Schools, were read and approved and the applicants were duly elected and enrolled as honorary members of the Raleigh Mining Institute. Upon motion, the meeting was adjourned and the members entered the banquet hall, where the address of welcome was delivered by the toastmaster. Tables were set for 150 persons. After the dinner, interesting addresses on diverse mining subjects were delivered by various menbers of the institute.

A New First Aid Packet

By Geo. B. Parker and B. T. Pollard

A new type of first-aid packet is about to be adopted by the Colorado Fuel and Iron Company for use in its mines. This packet (the invention of Dr. Gates) consists of two pieces of hard tin with smooth edges. Each piece of tin measures about 3x8 in., and is adapted for use as a splint. These two splints have lugs soldered thereon with attached strips of webbing suited for securing the tin plates to either side of a fractured limb. The lugs are turned inward and are arranged to be at reverse ends of the packet. In this manner they act as spreaders. An aseptic bandage is placed between the tin plates and an air-tight strip of soft solder is run around the edges so as to make an airtight packet.

Uniontown Section of H. C. Frick Coke Company's First Aid Corps, Taught by Dr. M. J. Shields, American Red Cross Society

In the side of the tank of a dinner pail a round hole is made and the packet is soldered to the pail through this hole. If the splints are torn from the pail, the tank is rendered useless and this fact is expected to make the miner or laborer apply for another. It is considered unlikely that any miner or laborer would be overcome by an accident without a first-aid packet being available as it is customary always for the workmen to take their pails with them when they are transferred from place to place.

The soft solder can be easily removed, leaving a splint without ragged edges. One important feature of this appliance is that it can be put into water and washed with the dinner pail without injury to the aseptic bandage.

First Aid Hints

By all means give your patient air. It is the safest and cheapest drug in the *Materia Medica.* Stand back if you are not needed and let nature do its work.

Roller bandages for the fingers should be $\frac{3}{4}$ in. wide and 3 to $4\frac{1}{2}$ ft. long; for the arm and head $2\frac{1}{2}$ in. wide, 3 to 6 yd. long; for the body and legs 3 in. wide, 6 to 8 yd. long.

If your patient, overcome by gas, is breathing, but can't walk around, don't drag him. Lay him out with his back on a flat surface. Roll a coat and place it under his shoulders and neck, so that his windpipe is straight. That will give him a chance to breathe without labor.

If you have been exploring after an explosion and come out with your lungs full of gas, nauseated and with a headache, you will want to sit down on a step and hold your head as people with sick headaches, and feeling weak at the stomach naturally do. Resist the impulse, get up and call a friend or two and let them walk you around. Get air into your lungs, hold up your head, take in deep breaths; don't constrict your lungs. No good will come of doubling yourself up. It is not rest or quiet you need so much as fresh air and a gentle stimulus.

Erratum—In our issue of last week, there appeared in this department a photograph captioned, "Banquet of Wilkes-Barre Mining Institute." The view in question was a photograph of the "Scranton Mining Institute Banquet," the word Wilkes-Barre having been printed by mistake.—Editor.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Alaskan Coal and the Administration

Secretary Fisher has had a consultation with President Taft for the purpose of discussing the policy of the Government in regard to the treatment of coal deposits in Alaska. Mr. Fisher has prepared and submitted to the President the details of his plan, which provides in substance that the coal shall be owned in perpetuity by the Government and that the leasing system shall be adopted for the control of the coal properties. The Secretary has discussed with Mr. Taft the form in which the recommendation should be made and has indicated the extent of the concessions to private interests which he believes may be made with advantage in order to induce them to undertake the exploitation of the coal.

It is probable that progressive members of Congress will lend their support to the leasing system and will not attempt to antagonize the main feature of the program of the Administration. They will, however, it is believed urge great modifications in the details with a view to what they consider the more effectual protection of the interest of the public in the lands.

War Department Coal Purchases

The Quartermaster General of the Army has just completed a report to the Secretary of War on the subject of coal purchases for the army in which he reviews the experience during the past year or two with the present system of purchasing and recommends new legislation to govern the purchases henceforward. It is not certain whether this legislation can be obtained but it is expected that Secretary Stimson will have the proposed change incorporated in the new army appropriation bill.

The report says in part: "In view of the excess prices frequently submitted by bidders for fuel over that at which fuel may be purchased in the open market, especially upon the Pacific coast, for that required in Alaska, and for use of transports, it is suggested that recommendations be made to the Secretary of War for enactment of legislation giving the Secretary of War authority to purchase, as in his discretion may be deemed for the best interests of the service, and in view of this suggestion the following draft is submitted: 'The Secretary of War, in making contracts and purchases, shall give the preference, all other things, including price and quality, being equal, to articles of the growth, production, and manufacture of the United States. In purchasing fuel and forage for the Army, particularly with reference to Alaska and island stations, the Secretary of War shall have power to discriminate and purchase, in such manner as he may deem proper, that kind and quantity of fuel and forage, not to exceed the supply necessary for a single fiscal year, as shall be best adapted to the purpose for which required.' "

The report further on, reads: "Attention is invited to the fact that the price for delivery of anthracite coal advances from April to August approximately 50c. per ton, and if authority of law and appropriation could be obtained for the purchase of anthracite coal in April for the succeeding fiscal year it would, based upon the consumption for fiscal year 1911, effect an annual saving of approximately $60,000, being about 8 per cent. saving on purchases of anthracite coal; this on the presumption that storage space for a year's supply is available at all posts using anthracite coal."

Upon the suggestion of the Geological Survey, in May, 1910, the Quartermaster's office took under consideration the question of purchasing coal for use of the Army based upon its heating value as expressed in British thermal units. The method then pursued was to purchase coal on its fuel equivalent, in which case the actual test of each coal was necessary before contractors could bid on same. After a careful consideration of the matter, the proposed method was approved by the Secretary of War in December, 1910, and all coal for the Army for the fiscal year 1912 has been purchased under this system. The question of extending this B.t.u. system to the Philippine islands is now under consideration.

Alabama

Birmingham—The Woodward Iron Company, of Birmingham, has purchased the properties of the Birmingham Coal and Iron Company, including 40,000 acres of coal lands, 2400 acres of high-grade ore lands, two blast furnaces, the mining town of Mulga and other properties. It is said that the deal represents $7,500,000, and that developments on a large scale are anticipated.

The Jefferson Coal Company, of Jefferson county, has filed in the United States court a petition in voluntary bankruptcy.

In the absence of a quorum of the reorganization committee, formal ratification of the merger of the Southern Iron and Steel Company and the Alabama Consolidated Coal and Iron Company, which was to have taken place Nov. 10, was indefinitely postponed. That the merger will soon become operative, however, is evident from the fact that the committee has received deposits of from 60 to 70 per cent. of the various securities of the two companies.

The new stockade of the Pratt Consolidated Coal and Iron Company at Flat Creek will not be ready for occupancy until the first of the year, and the State of Alabama will probably not be able to take charge of the Banner mine of that company under the lease entered into a short time ago until Jan. 1. The State was to begin the lease about Nov. 15, and work the mine with State convicts.

California

San Francisco—The Clear Lake Coal Company has been incorporated to develop a coal prospect in Lake county. The property consists of 1920 acres of Government land, on which a force of men, with an engine and pump, are sinking a shaft; the work is reported to be progressing satisfactorily.

The mine of the Stone Cañon Coal Company, in Monterey county, has been closed for more than a year. The company now is sinking the slope, previously worked at the 300-ft. level, to a depth of 1000 ft. and expects to mine coal from this level and market it about Jan. 1. The vein is alleged to be 14 ft. thick and to contain several million tons of good merchantable coal. The work of rebuilding the railroad, washed out in the spring floods of 1910, is progressing satisfactorily.

Illinois

Springfield—The Livingston mine of the New Staunton Coal Company, claims the tonnage record for the State. There were hoisted during the last half of October, 34,649½ tons, working 13$\frac{9}{16}$ days, making an average of 4029 tons per day. The record hoist, of Sept. 29, is 4265 tons, making 4192 trips and loading 105 railroad cars in eight hours. It is generally understood that Mr. Ross, of the Superior Coal Company's mine No. 3, at Gillespie, expects very shortly to beat these records for both day and week.

Chicago—The O'Gara Colliery Company, of Chicago, has been incorporated with a paid-up capital stock of $100,000.

The company has a large tract of coal rights north of Harrisburg, in Saline county, and development has already been started. This concern is not to be confused with the O'Gara Coal Company, although it is understood that the two are closely allied.

DuQuoin—Official announcement has been made of an extension of the Burlington's Southern Illinois coal line to West Frankfort, in the heart of the Franklin county field. The extension will branch off from the main line, south of Christopher, and continue in a southwesterly direction for a distance of about six miles to West Frankfort. Practically all the right of way has been secured and the work of construction will be well under way by the first of December.

Chicago—Consolidation of the City Fuel Company and the Lill-Robinson Coal Company, forming the largest corporation for the retailing coal business in existence, was perfected recently at a meeting of officers of the two concerns.

The concern, which will be called the City Fuel Company of Illinois, will have a total capital stock of $4,000,000. "The consolidation was effected solely for the purpose of economizing deliveries," said Fred W. Upham, the president.

Indiana

Indianapolis—The miners employed by the Domestic Coal Company of Kokomo, which recently was placed in the hands of a receiver, have been paid in full. The mine, which is in excellent condition, will be kept in operation.

Kentucky

Louisville—The organization of the Cambria Coal and Lumber Company, at Lexington, is said to mean that Pennsylvania capital is preparing to acquire immense areas of coal and timber lands in the mountain section of the State. Four companies, in all, have been organized. The capitalists back of the project have acquired 140,000 acres, and as individuals they hold 35,000 acres additional. The approximate value of the lands which they control is said to be about $1,500,000. These lands are in Perry, Floyd, Magoffin and Knott counties.

The several companies are as follows: Kentucky Land and Improvement Company, which controls 40,000 acres; Cambria Coal and Lumber Company, 67,000 acres; Knott County Coal and Lumber Company, 23,000 acres; B. F. Price Coal and Lumber Company, 10,000 acres.

The town of Jenkins, Letcher county, which has sprung up since the Consolidation Coal Company opened its mines there, now has a population of 1200, an average of 200 persons a month. It is estimated that it will have a population of 5000 in a short time if the percentage of increase keeps up, which seems probable.

Madisonville—The biggest coal deal in the history of this county was made Oct. 30, when President Ross, of the Kentucky Bank and Trust Company, bought the I. Bailey tract of coal lands at the edge of Muhlenberg county, for $23,000. The tract contains 4600 acres.

Montana

Roundup—Recently a new record was established by the Roundup Coal Mining Company's mine No. 3 at Roundup in the amount of coal hoisted in a single day. The mine is being worked at full capacity with a crew of 304 men and in one day of eight hours 1504 tons of coal were mined and loaded. Also a new record was established by mine No. 2 of the Republic Coal company, employing a force of 410 men, when 2020 tons of coal were mined and loaded in one day of eight hours at this property.

Ohio

Columbus—The bonded indebtedness of the Sunday Creek company is no longer backed by the Hocking Valley Railroad Company, as is disclosed by the last fiscal report of the latter. This is in conformity with a decision of the courts on ouster suits compelling divorcement between the railroad and coal properties.

The Meister Coal Company of Fushing, Belmont county, has been incorporated with a capital of $75,000 to mine and sell coal.

Bridgeport—The movement toward the consolidation of practically all the big coal companies in eastern Ohio has taken on definite shape. The proposition is up to the syndicate which will furnish the money and a favorable reply in anticipated. The consolidation would embrace 11 or 12 of the largest companies in the eastern half of the State and about $25,000,000 would be involved. It is said the proposed organization would virtually control the output from the district and would be able, in a measure, to fix prices.

Pennsylvania

Bituminous

Punxsutawney—Eight men perished in an explosion in the Adrian mine of the Rochester and Pittsburg Coal and Iron Company shortly after 6 o'clock in the morning of Nov. 9.

With the aid of the rescue crew from the United States Bureau of Mines of Pittsburg, the rescue crew at the mine later took out six bodies, but was unable to penetrate to the seat of the explosion on account of the afterdamp and débris. Two other miners are believed to have perished under a crushing weight of fallen rock. The cause of the explosion and fire is as yet not definitely known. The damage to the mine proper was slight.

Altoona—Bondholders of the Pennsylvania Coal and Coke Company met Nov. 10 at Philadelphia to ratify the plan for the reorganization of the company proposed some months ago. The plan provides for a foreclosure of the consolidated mortgage and a sale of the properties held by the receiver, which are not subject to the lien of the mortgage. The new company will be capitalized at $7,500,000, and will be authorized to buy, lease and operate coal and other lands and sell their products.

Boswell—The Merchants' Coal Company is spending about $100,000 in improvements, which will increase the output from 2000 to 3500 tons daily and give employment to 300 more men. The improvements include an enlarged tipple, two dumps for loading coal, new crusher, new fanhouse, new haulage engine, and an addition to the power plant to house a new generator and boilers.

Cassandra—According to authoritive information, work will soon be started on the opening of a new mine by the Shumaker & Hughes Company to tap a large coalfield lying north of this place.

Anthracite

Scranton—Shipments of anthracite in October amounted to 6,269,179 tons. This establishes a record for October, being an increase of 161,114 tons over the previous record for that month, made in 1907. Last month's shipments were 647,084 tons in excess of October, 1910.

The shipments from Jan. 1 to Oct. 31 amounted to 57,645,558 tons, as compared with 52,602,462 in the corresponding ten months of 1910, an increase of 5,043,096.

Incorporation papers were filed Nov. 8 by the Connell Anthracite Coal Company, capitalized at $10,000. William J. Connell and James S. McAnulty, both of Scranton, are directors.

Testimony in the equity suit of the Delaware, Lackawanna & Western Coal Company to recover $90,000 from the North End Coal Company for coal alleged to have been illegally mined, was heard recently by Judge H. M. Edwards. It is alleged by the plaintiff that the North End company has violated the terms of lease by going beyond the boundary lines and taking 60,000 tons from the Lackawanna's property. It is asking 50c. a ton and treble damages amounting to $90,000. The North End company will attempt to prove that it followed the lines laid down in the lease as closely as possible, and that if its operations did extend beyond the lines it was done inadvertently and that the coal mined did not amount to any substantial quantity.

Shamokin—The Pennsylvania railroad is storing a great quantity of coal at its new yards near Northumberland.

Wilkes-Barre—A mine cave recently occurred in a crowded street at Plains. The subsidence left a hole about 15 ft. wide, 20 ft. long and 20 ft. deep, and wrecked several houses.

Pottsville—The Alliance Coal Company, a subsidiary branch of the Lehigh Coal and Navigation Company, in the Panther Creek valley, has purchased the Maryd colliery from J. S. Wentz & Co.

Hazleton—It is understood that the proposed new Spring Brook washery of the Lehigh Valley Coal Company at Audenreid will be electrically operated throughout.

Rhode Island

Providence—Operations at the Rhode Island Coal Company's plant have been started after a 10-days' suspension to permit double tracking of the slope and other improvements. The company expects to produce daily 500 tons of coal.

Tennessee

Nashville—The Bon Air Coal and Iron Company plans to organize a new company with $3,000,000 capital stock to take over and develop its properties, which include 38,000 acres of coal and timber land in two counties and 80,000 acres of iron and timber land in five counties of Tennessee.

Memphis—Special Examiner Anderson, for the interstate commerce commission, recently began hearing testimony affecting complaints against a 10 per cent. increase in the freight rate on coal shipped to Memphis from Illinois, Kentucky and Alabama by the Illinois Central, Louisville & Nashville and St. Louis & San Francisco railroads. The increase became effective April 1 last. Local coal consumers complained. A decision by the commission is expected in 90 days.

Washington

Palouse—At a meeting of prominent business men of Palouse, a syndicate was formed to develop a coal find on the Ellsworth Bishop ranch, on Cedar creek, four miles north of here. It is announced that work will commence on the property at once, a contract having been already completed with an Idaho coal miner for sinking a 200-ft. shaft.

Centralia—Franklin A. Umstead, of Chicago, has purchased the Great Western coal mine, located a few miles south of Tenino. It is hoped that the sale will mean a big boost for lignite coal in this vicinity.

Seattle—The Mendota mine of the Mendota Coal and Coke Company is now producing 600 tons of coal daily. The property is located ten miles from Centralia and comprises 9000 acres which are underlaid by six workable veins. The seam being worked at present is 10 ft. thick.

West Virginia

Fairmont—The Consolidation Coal Company recently established an office in London, and all foreign business will be handled from the European branch.

Charleston—The New River Collieries Company, operating the Sewell and Beckley seams in Raleigh county, is now shipping from four shafts, and has an output of 25,000 tons which it hopes to increase to at least 40,000 tons within the next two months. This company has 8500 acres under lease.

The incorporation of the Southern Collieries Company, of this city, for the purpose of mining coal and cutting timber in the Cabin Creek district of Kanawha county, means another large development along the Cabin Creek branch of the Chesapeake & Ohio railroad. The development of properties along that line during the past year has necessitated the practical reconstruction of the branch railroad in order to handle the coal and timber, but especially the coal. The Southern Collieries Company has an authorized capital of $100,000.

Canada

Nova Scotia—A renewal for two years of the agreement between the Dominion Coal Company and the Provincial Workmen's Association has been concluded. This renewal will hold good until the close of 1913, and is on exactly the same terms as the present agreement.

Personals

Edward Cameron has been appointed manager of the Natchez, Miss., office of the Pittsburg Coal Company.

O. D. Hogue has been appointed vice-president and treasurer of the Goulds Manufacturing Company, of Illinois.

E. P. Merrill, formerly at Pachuca, Mexico, is now in charge of the western business of the Island Creek Coal Company, with headquarters at Minneapolis.

P. C. Thomas, formerly a mining engineer with the Temple Iron Company and later with the H. C. Frick Coke Company, has been appointed chief engineer of the New River Company, with offices at MacDonald, West Virginia.

Waldemar Lindgren has been appointed chief geologist of the United States Geological Survey to succeed C. Willard Hayes, who recently resigned. Mr. Lindgren has been a member of the Federal Survey since 1884 and has been in charge of its investigations in metalliferous deposits since 1907. He is the author of some 50 reports published by the Survey, and in addition has contributed between 50 and 60 articles to technical and scientific journals. Mr. Lindgren is a trained mining engineer and has a world-wide reputation as an authority on the geology of ore deposits.

Obituary

The death of J. K. F. Steele, of Keystone, W. Va., removed one of the pioneer coal operators of the southern section of the State. Mr. Steele came to West Virginia from Stewartstown Furnace, Penn., about 22 years ago, to enter the employment of the Indian Ridge Coal Company, and later became interested in the Keystone Coal and Coke Company, at Keystone, of which company he was general manager at the time of his death.

Requests for all papers cannot be granted without satisfactory reason. Bulletins, 24, 27, 28 and 35 will not be sent to persons who received the original bulletins. In asking for publications please order them by number and title. Applications should be addressed to the Director of the Bureau of Mines, Washington, D. C.

West Virginia Geological Survey

Detailed County Report, on Wirt, Roane and Calhoun counties, 573 pages + XX, with case of 3 maps—topographic, geologic and soil—published under date of July 1, 1911, and now ready for delivery. Besides the detailed study and description of all the rocks, minerals, soils, streams, industries, etc., found within the area, the geologic map gives also the true location of all the oil and gas pools developed up to July 1, 1911, and shows by structural contours the several anticlinal and synclinal arches, including the southern extension of the famous Burning Springs or Volcano anticlinal. Price, with case of maps, postage paid by the Survey, $2. Extra copies of geologic or topographic map, 50c. each. Order from the West Virginia Geological Survey, Morgantown, W. Va., Lock Box No. 448.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The past week has witnessed a sharp flurry in the coal market, due to the first general break in the weather this season. The spot market has tightened in all sections, with prices firm, and a shortage in transportation facilities becoming acutely evident in some districts.

In the extreme East the market is normal generally, with a fair demand for spot coal of the better grades. A shortage in some sizes is appearing and the recent storms will, no doubt, stimulate the market all along the line.

The cessation of Lake shipments in the East has left the market unsettled, but the unprecedented fall in temperature will result in a heavy demand for domestic. Shortages in some sizes are reported, and dealers are beginning to consider the possibility of a strike next fall.

Ohio mines are estimated to be working 80 per cent. capacity, one of the strong features being the Lake trade. Transportation troubles are developing here and down through West Virginia, but not in serious proportions yet. It is believed 60 to 75 per cent. of present production is contract coal.

Through the Middle West conditions are variously reported as quiet or improving with an occasional instance of overstocking and weak prices. The Rocky Mountain States still continue with a heavy consumption, which is taxing the capacity of the mines and railroads. Pacific Coast operators are working full time with trade normal.

Boston, Mass.

Bituminous seems to be marking time this week; there cannot yet be said to be a seasonable demand for spot coal, and contract requirements are steady enough to keep the situation generally firm. At the Virginia terminals $2.60 f.o.b. remains the base price for Pocahontas and New River, with but few sales reported. There is not quite the rushing anxiety to get fuel forward that was evident ten days ago.

Arrivals have been better, and a supply of tonnage is in prospect, but freights continue firm at high figures, 90c. to $1 being the rate to Boston, depending on size and draft.

Prices at Mystic Wharf on cars are from $3.63 to $3.68 on the better Southern coals. The cold wave reported to be on the way should cause a decided change in the market here and we are likely soon to see higher prices along with higher freights. The textile mills are enjoying fair business, and general prospects are somewhat brighter.

In anthracite trade continues active. The better movement of boats is helping out, but barges are still short and the companies slow on delivery. Retail trade is brisk, and the demand for chestnut is still an important feature. Surprisingly little interest is shown in possible labor troubles next April and the dealers, outside of the points soon to be closed to navigation, seem only to be looking out for present needs. It is true that the companies seem to have their hands full looking out for those.

New York

Market conditions here this week show but little change from those prevailing during the past two or three weeks. Railroad movement to New York tidewater, with few exceptions, is prompt and the supply at the piers is fully adequate to the demand, which on contract is good, although the movement from the piers is reduced to some extent by reason of the unfavorable weather for transportation on the sound. This has held back the boats considerably and delayed somewhat the movement from the piers.

The market for inferior coals shows no improvement whatever and some of these grades on demurrage are offered at sacrifice prices.

On new business the market is very dull. Consumers are getting all the coal required from contract sources so that the amount of new business coming into the market is about at a minimum. The possibility of labor trouble in the spring has as yet caused no decided increase in the demand for soft coal. This contingency will undoubtedly have a strengthening influence on the coal business in general as the first of April draws near. The excellent demand that has prevailed on contract this fall, may in some measure be traceable to this possibility. Rail business in this territory is in good condition and a large tonnage is reported as moving.

Prices obtaining in this market for steam coal, with the exception of the prices made to get rid of demurrage are unchanged from those previously reported, ranging f.o.b., New York, about as follows: $2.35 for West Virginias (80c. at the mines); $2.35@2.45 for ordinary Pennsylvanias; $2.55@2.65 for good Pennsylvanias, and better grade Pennsylvanias, $2.65@2.75.

Buffalo, N. Y.

The feature of the coal trade just now is the scarcity of both anthracite and bituminous. Anthracite dealers have complained of a lack, especially in stove, for some weeks, but bituminous has been plenty enough and it would be now, but for two features of the trade, only one of which will last. The miners have been badly demoralized of late, the hunting season, the Pittsburg convention and the election conspiring to keep them idle. The other difficulty is the growing shortage of cars.

The improvement in soft coal is still small. It will need to be much larger than it has been yet to affect prices, beyond preventing the offering of slack at all sorts of prices, as has been done through the summer. Slack is stronger now and if the Lake trade takes as much of it as it should there will be but a small surplus at the close of the Lake season and prices will continue to strengthen, though they are not likely to advance right away. It is believed that under normal conditions the natural supply is too large for that.

Some report is made of a prospective coal famine in the Northwest, especially Canada, the coming winter, but anthracite shippers say that they, at least, have enough on docks at the head of the Lakes, even though they do expect to have a call for it further west than usual, on account of the strikes in Rocky Mountain mines. So this condition will keep soft coal moving by Lake as long as the vessels can go. The condition of the closing Lake trade has much to do with the soft-coal situation during the early winter.

Bituminous prices remain fairly steady, except for slack, on the basis of $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack, with Allegheny Valley about 25c. less. No stir is evident in coke, which is weak at $4.25 for Connellsville foundry, to $3.50 for stock.

The smithing situation is steady, a fair amount moving at $4 for Georges Creek Cumberland and $3.65 for Cambria county. The practice of using a large percentage of slack for smithing purposes keeps prices down.

Pittsburg

Bituminous—The coal market is rather unsettled since the practical cessation of lake shipments, prices being somewhat more irregular, while production is restricted. Shipments to retail coal yards and to manufacturing consumers increased slightly this week. Genuine winter weather appeared with a suddenness that has rarely been paralleled, the temperature dropping over 30 degrees in a few hours and the movement in the domestic trade this week will undoubtedly be very heavy. We repeat former quotations, which represent approximately the average level of the market: Nut, $1@1.05; mine-run, $1.05@1.10; ¾-in., $1.15@1.20; 1¼-in., $1.25@1.30; slack 40@50c. per ton at mine, Pittsburg district.

Connellsville Coke—Sales of between 60 and 75 cars of furnace coke have been made in the past week, about 3000 tons, all at $1.50. Several consumers have been buying an odd lot each week for several weeks past, which accounts for the steadiness in the sale of spot furnace. Otherwise the market is very dull. One furnace in the East goes out this week, but another goes in, while in the Central West the furnace operations are practically unchanged. Some negotiations have been on for furnace coke for next year. As a rule, buyer and seller are far apart, but one or two contracts may be closed within a few days. The majority of buyers seem to be inclined to wait for at least 30 days before going deeply into the matter of contracts. Many contracts, of course, run into or through next year. Foundry coke continues quiet, with fair shipments on contract. We quote: Prompt furnace, $1.50@1.55; contract furnace (nominal), $1.65@1.75; prompt foundry, $1.80@1.90; contract foundry, $2@2.25, per net ton at ovens.

The *Courier* reports production in the week ended Nov. 4 at 322,745 tons, an increase of 2000 tons, and shipments at 4058 cars to Pittsburg, 4933 cars to points west and 1043 cars to points east, a total of 10,034 cars, an increase of 907.

Philadelphia

The week opened with a splendid effort on the part of the weather man to make matters easy for the retail trade. Temperature here dropped anywhere from 25 to 35 degrees, and, as a result, the dealers were swamped with new business, and urgent telephone calls for orders to be filled that were in hand. Shortage of coal is reported, particularly stove and chestnut, presenting an opportunity that the individual operators will hardly fail to take advantage of, by asking a premium for their product. All sizes are in good demand, and weather such as inaugurated the present week, is likely to cause a shortage all along the line. While it is understood that the large companies have some stocks of the small sizes, yet they are entirely inadequate to stand any unusual drain upon them, and it is believed that the first of the year will see these stocks pretty well depleted.

The conditions in the wholesale market are good, and the outlook is more than promising. Shortage of coal is also reported in this branch of the business—following the whole list, with stove and chestnut as leaders. The heavy storm early in the week, has interfered very materially with the movement of coal at Tidewater, barges and vessels being very seriously delayed, which has upset calculations very much, but this will give the companies an opportunity to throw more coal into the local market, where it is urgently required. Compared with last year, it is reported that the companies show a very appreciable increase, and all are looking forward to another record-breaking month.

The bituminous trade took a little flurry in the way of better business, and it is also reported that Pennsylvania coals are advancing a trifle in price

Baltimore, Md.

Although by no means active, market conditions in Baltimore during the past week have shown a slight improvement over previous weeks, and coal operators were more optimistic than they have been for months.

The demand for Pennsylvania and West Virginia coals was somewhat better, due to the fact that many buyers entered the market for winter coal. Others who were not in particular need of an oversupply, did some purchasing for storage purposes, believing that the coal operators will face trouble with the miners next April when their wage contracts expire.

What coal is being moved under contract, and otherwise, is delivered without delay. The railroads, including the Baltimore & Ohio and the Western Maryland Railroads, the two principal roads which supply this market, have kept traffic moving freely. There is no more talk of car shortages, which prevailed to such a large extent during the first six months of last year. The roads are well supplied with equipment, and can handle all business given them.

The coke market has shown but little life here for months, and at the present time, is exceedingly inactive. Most of the steel companies are entirely out of the market for the product, and orders are rare. Many coke ovens are idle on account of a lack of business.

Cleveland, Ohio

There is nothing to relate in regard to the lake-trade coal business, excepting there is a demand at the present time for medium-sized coal boats for cargoes to Michigan points. There has not been any improvement in the steam or domestic business in the past week. The cause in the domestic demand is owing to the very mild weather, which has continued during the past week and up to the present writing.

Slack is the only commodity that has increased in demand and also in price. This has increased in the past 10 days from 15c. to 25c. per ton, and will still increase as the closing of navigation progresses.

The general impression among coal dealers is that conditions look very much better than they have for some time past. Prices range as follows, per ton:

Ohio No. 8:	
Mine-run	$0.95@1.00
¾-in.	1.05@1.10
1¼-in.	1.15@1.25
Slack	0.55@0.65
Middle District:	
Mine-run	$1.00@1.10
¾-in.	1.20@1.30
1¼-in.	1.45@1.60
Slack	0.80@0.85
Youghiogheny:	
Mine-run	$1.10@1.20
¾-in.	1.30@1.35
1¼-in.	1.40@1.50
Pocahontas:	
Mine-run	$1.00@1.10
Lump	2.10@2.25

Columbus, Ohio

Conditions in the coal trade in all parts of the Buckeye State improved materially during the past week, the demand for the domestic grades has increased and prices are firmer all along the line. The chief cause for the betterment is the lower temperatures which have prevailed, as well as the approach of the time usually taken for stocking up. On the whole the market is in good shape and operators, jobbers and retailers are looking forward to a better trade during the fall and winter.

Dealers in cities and towns also report a better demand for all grades of domestic coals. The larger consumers are laying in their supply and the retail trade has been active in the extreme. Better weather has enabled the dealer to deliver promptly. Retail prices are firm but have not yet reached the usual winter level.

One of the best features is the continued activity in the Lake trade. Operators are rushing their mines in order to get as large a tonnage as possible to the Northwest before the close of navigation. The tonnage moved to date is larger than usual and it is believed the amount shipped to the Northwest from Ohio will surpass that of last year by many tons. There is little or no congestion on the docks at the upper Lake ports and the movement to the interior is good. Dock prices rule firm.

Production in the various Ohio fields has been rather active during the past week. It is estimated that the output has been about 85 per cent. of normal in the

strictly domestic fields and about 75 per cent. of normal in the other mining districts.

Prices prevailing per ton in Ohio are: Domestic lump in the Hocking Valley, \$1.50; domestic lump in Pomeroy Bend, \$1.60@1.70; ¾-in., \$1.35; nut, \$1.15; mine-run in the Hocking Valley, \$1.05@1.15; mine-run in eastern Ohio, 95c.@\$1.05; coarse slack, 35@45c.; nut, pea and slack, 40@50 cents.

Cincinnati, Ohio

The unexpected warm weather is responsible for the domestic stagnation which is now in evidence as well as the weak steam demand. This, however, can be only temporary. The big bulk of the business cannot be seriously affected by temporary and minor conditions which are only incident to the business. The amount of "free" coal—that is, that not contracted for—is estimated variously at 25 to 40 per cent. of the total output. The remaining 60 to 75 per cent. will continue to move right along under contracts signed months ago.

There is an increasing amount of speculation as to what the effect of the threatened labor difficulties will have upon the fuel market. It is generally believed that the difficulties of two years ago will be repeated and probably intensified. The anthracite miners have made known their demands for a 20 per cent. increase in wages.

Just now the stocks of coal are sufficient to keep the demand down to a minimum but in the event of any trouble, whether from labor or other causes which would hinder operations or tie up deliveries, present stocks would soon disappear and the demand would jump at once. It is not believed that demand uninfluenced by some such outside agency will be materially increased before the first of the year. But the determination of men in the local trade seems to be to maintain a neutral position until after the first of the year. The tone of all the offices is optimistic, and they seem to feel that having been for 10 months without material change they must soon come to the proverbial turn in the lane. In some of the offices there is met the declaration that their business has been good under all the circumstances and that they really have "no kick coming."

Thurmond, W. Va.

Conditions in the New River coalfield, along the Virginian and Chesapeake & Ohio Railways, are in a decidedly mixed-up condition. Operators along the Virginian have an ample car supply and run every day, while the operators dependent on the Chesapeake & Ohio Railway alone are only working about four days a week. Operators in the Chesapeake & Ohio Railway district, who have track connections with the Kanawha, Glen Jean & Eastern Railroad, popularly known as McKell's road (McKell Coal and Coke Company) and with the White Oak Company's road, both of which now connect with the Virginian, also have an ample car supply and run every day.

Then of the large selling agencies handling the coal from this field, some have large amounts of coal at tidewater and few vessels chartered, while others are short of coal, both at Sewalls Point and Newport News.

During the first ten months of this year, the Virginian Railway dumped over its Sewalls Point piers 1,622,534 tons. This road has just issued a little pamphlet descriptive of its Sewalls Point piers, giving some of the loading records they have made, which are quite remarkable.

As showing how far below their rated capacity the mines in the New River field along the Chesapeake & Ohio Railway are loading, the following statement is given of the four largest mines in the district and what they should have loaded, based on their actual tonnage allotment per day, with twenty-five working days allowed:

Name of Mine Shipping	Tons Actually Loaded	Tonnage-allotment Capacity	Per Cent. of Capacity Loaded
Sun	30,870	47,500	65.0
Raleigh	17,100	37,500	46.0
Klondike	10,410	32,500	50.5
Star	13,460	22,500	60.0

Nashville, Tenn.

Domestic business in this field is entirely satisfactory, with mines working full time, and so far no trouble has shown itself in the way of shortage of cars with the Louisville & Nashville Railroad.

Prices are ranging just about the same as usual at this time of the year, which are as follows per ton:

Standard lump	\$1.25
Nut coal	\$0.90@1.00
Screenings	0.25@0.30

The demand for steam coal is not as good as it might be and the mines making a specialty of furnishing steam plants their requirements, are complaining about the dullness on steam coal. The prevailing price on mine-run coal is from 80@90c. per ton, according to district from which the coal moves.

From this time on it will be strictly a weather-market proposition in this field on domestic coal. A spell of severe weather, lasting for some little time will advance the price on domestic coals; otherwise on account of the large overproduction in this field the present price on coal for the season will very likely remain unchanged.

Louisville, Ky.

A drop in temperature from 74 to 18 degrees in twelve hours in this locality precipitated a raid on the coal dealers. Different retail dealers are advertising a 2000-lb. ton, due to a lively controversy which has occurred in the general council of Louisville, as to what constitutes a ton of coal. Jellico coal is being advertised as low as \$3.60 per ton, Straight Creek, \$3.75, and Kentucky Lump, \$3.75, with Pittsburg at 14c. a bushel. The activity in coal centers in Kentucky is being duplicated in the mining districts as well.

In the western part of the State the inactivity due to the Illinois Central strike is fast disappearing. More cars are being placed at the disposal of the mines with which to handle their coal. In the Middlesborough district there is much activity; this field, while not a new one, continues to develop rapidly.

Indianapolis

The weather during the last week has been the key to the local market. The first few days of cold weather occasioned some increasing interest and strength, but when followed by warm weather the market lagged and showed weakness. It is apparent that every new touch of winter makes a draft upon the retailer, and directly through him on the wholesaler. These are indications that both consumers and retailers are depending mainly upon the day-to-day supply of coal, adopting this plan of depending on the open market with entire confidence.

Conditions relating to steam coal remain practically unchanged. Manufacturers are still confident that business will soon take an upward turn and trade generally speaking is hopeful. However, the developments of the last few weeks show a depressing effect on the coal trade in general, due, it is said, to the threatened attack by the Government against the big interests, and in particular the Steel Corporation. Because of these and other hindrances, it need not be expected that there will be any perceptible improvement in the steam-coal demand and consumption during the remainder of the year. The operators freely admit that their dependence is placed on whatever profit they may derive from consumers in general. There has been no change in the price of coal since November 1.

St. Louis, Mo.

Conditions in the St. Louis market were somewhat better the past week, because of the change in the temperature. There had been a slight increase the week previous, but during the last week prices have been practically stationary as a whole. Car supply occasioned a sharp demand on one or two days, but other than that there was nothing extraordinary about the market.

It is almost beyond understanding why the market still hovers around the cost of production price, especially on the inner belt coals. Higher-grade coals from

the outer district advanced slightly and were in fair demand, but the bulk of the tonnage moved to the country.

One extraordinary feature of the present season is the fact that the railroad companies are not buying in the volume that they have heretofore at this time of the year. As a matter of fact, right now a lower price is asked at the rate of 50 bushels of Standard lump coal than for a thousand bushels. This is retailing on track in wagon-load lots at from $1.50 to $1.62½ per ton, and the operators are asking $1 at the mines with a 52c. rate, to which must be added the shrinkage and other losses. This is the first time that anything like this has occurred in years, and there seems to be no immediate remedy for it. The cause of this is laid to one or two of the larger companies in St. Louis, who have the output of the Standard mines, and who are endeavoring to drive the retailers out of the carload business. Indications are that the higher-grade coals will continue to bring a good price, while there is very little hope for coals from the Standard field of the lower grade.

The prevailing prices per ton are as follows:

Standard:

2-in. lump	$0.95@$1.05
6-in. lump	1.00@ 1.10
No. 1 nut	0.75
No. 2 nut	0.60
2-in. slack	0.30

The Mount Olive and Staunton coals are still selling at from $1.25 to $1.35, and the higher-grade coals from the inner belt are selling at from $1.75 to $2.10.

Franklin County Coal:

6-in. lump	$1.60@$1.75
3x6-in. egg	1.60@ 1.75
No. 1 nut	1.50
No. 2 nut	1.30
No. 3 nut	1.00

Williamson County Coals (Carterville):

6-in. lump	$1.50@$1.65
3x6-in. egg	1.45@ 1.60
No. 1 nut	1.15@ 1.25
No. 2 nut	1.00@ 1.10
No. 3 nut	0.90
2-in. screenings	0.45
Mine-run	1.00

Minneapolis—St. Paul

There is a splendid tone to the retail market. The time was when the Twin Cities coal supply came altogether from the head of the Lakes docks, but for several years past, the all-rail coal from Illinois, principally Southern Illinois, has found a large place in the domestic market. All-rail coal is also used to a considerable extent in the steam trade.

There has been no change in dock coal prices, anthracite remaining at $9 for stove and egg, chestnut at $9.25, pea at $7.75, buckwheat at $6.25, delivered in consumers' bins. Hocking, $5.75, Youghiogheny, $5.75. All-rail, washed nut and stove $5.50. Smokeless $7.25.

Carload prices for domestic coal are firm on dock coal, $3.50 for Hocking and Youghiogheny at Duluth-Superior docks. All-rail coals are held very firm at mines, Franklin county lump and egg and No. 1 at $1.75, and stove and washed egg, $2; No. 2 at $1.50, sometimes called special stove.

Carterville lump and egg, about $1.75; washed egg $2; washed nut $1.75. Coals from Springfield and vicinity are held at $1.75 for egg and $1.50 for washed nut.

Portland, Ore.

Australia coal to the extent of 6000 tons was brought here this week by the British steam "Strathearn," from Newcastle, N. S. W. This is the first coal cargo to arrive here this season from Australia, and it will not be followed by more than the four or five vessels now listed. The importation of Australian coal to this port has decreased materially during the past five years, due largely to the introduction of domestic coals. About seven years ago the importation for one season amounted to approximately 70,000 tons. The fact that the railroads and steamboats are using oil fuel extensively is also responsible for the decreased shipments from Australia.

The weather of the past week has been more favorable to the fuel dealer, although by no means such as to create a sudden demand for coal.

Following are the prices asked here per ton, including cost of delivery to points within the city proper:

Japanese		$7.50	
Washington lignite	$7.00@	7.50	
Australian	10.00@	10.50	
Rock Springs, Wyo.	10.00@	10.50	nut $9.50
Diamond, Wyo.		10.00	
Carbon Hill, Wash., lump		10.50	
Carbon Hill, steam		7.50	
Newcastle, Wash.		7.00	
Beaver Hill, Ore.	9.00@	9.25	
Blacksmith coal		17.00	

San Francisco

The arrivals for the week by water are limited to one cargo from Australia of 3739 tons. Notwithstanding the light arrivals, and providing there are no mine strikes, accidents or lockouts, we see no cause for apprehension in this market. There are ample supplies of Australian to meet all existing demands.

Domestic consumers are favored with continued mild weather, no rain or cold weather having visited this section for more than a month.

The mines of the Puget Sound and British Columbia districts, from which most of our coal is received, are working full time, with increased output, and have a local demand for nearly all they produce, making them comparatively independent of this market. Prices are firm, with no immediate prospect of change, and the demand is quite satisfactory, considering weather conditions.

The car shortage referred to last week still continues and the dealer with a confirmed habit of living on the "hand-to-mouth" policy is registering his usual inconsistent "kick."

The wholesale prices, ex-bunker or at ship's side, are as follows, per short ton:

Wellington, clean	$8.00
Wellington, average	7.50
Australian, clean	8.00
Australian, average	7.50
Puget Sound, clean	6.50
Puget Sound, steam	$5.00 and 5.50
Pennsylvania anthracite	15.00
Colorado anthracite	12.50
New Mexico anthracite	13.50
Anthracite briquets	10.00
Cumberland, smithing	12.50
Utah, Wyoming and New Mexico, clean (for domestic use only)	$9.00 and 8.00

Foreign Markets

Great Britian

On the whole the coal trade of the British Isles has shown a little more activity, but delivery orders are by no means large. This has not had any tendency to reduce the prices, either those publicly advertised or the whole pit prices, and with the heavy accumulations of back orders disappearing the collieries are not averse to hold up a reserve supply in view of the demands winter will necessarily make. It seems too that the winter demand will be brisk, as the weather has certainly given many indications of a hard fall and winter. The Newcastle and Durham markets are firm, prompt and vigorous, and steam coals at Durham are in brisk demand. The house-coal trade of Lancashire is in good demand, while in the South Wales district the greatest attention is being given to the acquisition of the Welsh Navigation Coal Company's interests by Messrs. D. Davis & Sons, Ltd. This combination is one of the most important in the trade effected in recent years and the progress of the combine will be watched with interest. Some prophets have already been forecasting a huge combination of all the coal interests in South Wales. The Scottish Coal trade continues active in all branches as does the trade in South Yorkshire.

Chartered tonnage continues to arrive fairly well, and with a better demand for large coals over the remainder of the year, prices are stiffening. More attention is also being paid to contracting over next year. Quotations are approximately as follows:

Best Welsh steam coal	$4.08@$4.14
Seconds	3.84@ 3.90
Thirds	3.63
Best dry coals	3.96
Best Monmouthshire	3.66@ 3.69
Seconds	3.54@ 3.57
Best Cardiff small steam coal	1.92@ 1.98
Seconds	1.80@ 1.86

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive for wharfage and for cash in 30 days, less 2½ per cent.

Spain

Imports of coal into Spain for the eight months ended Aug. 31 were 1,398,060 metric tons, an increase of 50,031 tons over 1910; imports of coke, 206,464 tons, an increase of 16,261 tons. Substantially all these imports come from Great Britain.

"The Dean Boiler Tube Cleaner has paid for itself. We removed over 300 pounds of scale from a boiler that we thought clean."

ALEXANDER COAL CO., *Goff, Pa.*

Have You Also Misplaced Your Confidence?

Our business is a funny one for we do our best work by breaking other people's illusions.

Many Mine Superintendents have fought the scale evil in their Boiler Plant by compounds, water purifiers, etc., and like the company quoted above have thought their boilers clean until the Dean proved otherwise.

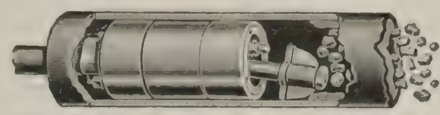
Misplaced confidence of this sort is costly, for it not only means more boiler repairs, shorter service from boilers, and greater consumption of fuel, but it also means what is more to be feared—namely, a lessening in steaming efficiency and a liability of complete shutdown.

The Dean eliminates misplaced confidence and gives a *real* confidence, for it removes all scale surely from the boiler tubes. And you can prove so yourself by sending for one on trial and seeing it remove scale, the presence of which you had never suspected.

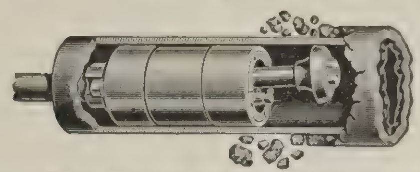
Economy is desirable in the power plant of the coal mine as elsewhere. Efficiency is essential to the power plant of the coal mine. The Dean is a valuable aid in securing both. *Try it.*

The Wm. B. Pierce Company

335 Washington Street — Buffalo, N. Y.



The Dean removing scale from the tube of a water tube boiler.



The Dean removing scale from the tube of a return tubular boiler.

Trial Offer and Guarantee

We send the Dean Boiler Tube Cleaner for free trial on one boiler. The Mine Operator, Superintendent or Manager can see how it operates and prove to his own satisfaction that it removes all scale.

We sell the Dean under a guarantee that it will pay for itself within six months or we will refund money.

Read that letter at top of this advertisement again and you'll see why we can make such a guarantee.

Accept our trial offer today.

SITUATIONS WANTED

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Position wanted with coal company in West Virginia as mine superintendent, engineer or mine boss; have West Virginia mine foreman's certificate; age 33; 19 years' experience in mining; can furnish good references. Address Box 2, care COAL AGE. Nov. 25.

POSITIONS VACANT

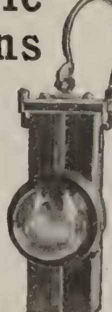
Advertisements under this heading 5 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—Experienced executive and manager of bituminous coal operation with engineering experience. Address Box 3, care COAL AGE. Nov. 25.

Hubbell Electric Safety Lanterns

Ideal for MINE Use

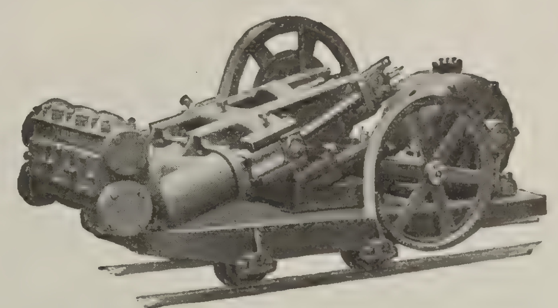
For general use about the mine, the officials' and Miners' Hand Lantern here shown is unequalled. It is excellently adapted for work in tunnel headings, for use with rescue apparatus or coal punching machines. Cost of operation is only about half that of any oil lamp. *Write for catalog.*



PORTABLE ELECTRIC SAFETY LIGHT CO.

14 Johnson Street, Newark, N. J.

Deming Electric Mine Pumps



WHEN you strike a water pocket in some part of your mine where no pumps are installed, what good is your stationary steam pump?

This Deming electric driven, *portable* mine pump can be taken any place your tracks lead to. *Write for particulars.*

COAL AGE

Vol. 1 NEW YORK, NOVEMBER 25, 1911 No. 7

MR. MINE FOREMAN—You have read so many admonitions suggesting that you should have all the virtues of the Stone Figure of Justice over the county-hall clock, that you may pass this one up; however, a thought lies edgewise in my mind like a herringbone across one's gullet, and won't down.

You have arrived at an old mine, where the tonnage cost is too high, or the output too low, perhaps both—they usually hunt in couples.

What are you going to do about it? Will you laugh and say, "I'll make the old fellow dig down into his jeans and get some equipment here."

I never saw that scheme tried but it failed. And why? Because the man who thinks in that way is usually trying to get the other fellow to solve his problems for him. And when the equipment is obtained, he hasn't the men, or the mine works slow time, or somehow things are out of joint.

It's foolish to say, "Give me an appropriation and I'll give you cheap tonnage." You're promising sufficient men, a steady market, and no accidents. It's far better to go easy, and look around. Let everybody know you're boss, but don't think you have to make good the first day.

And now look for the best investment money will bring. In nearly every mine, there are opportunities (some temporary, others permanent) to employ capital so as to net 100 per cent. each week. This first investment should be one which won't show up on the semi-monthly roll, and will be totally absorbed by the quick profits. And in figuring profits, don't forget tonnage; when the mine isn't making its capacity, larger output can be cared for without extra handling cost, during the gossiping time of the men.

The shooting of a small hill in the mine—in a place where doubling is necessary; the ditching of a dip which will cut out a compressed air pump and give a "puncher" a better show; the laying of a longer pipe line through and beyond a sag so as to avoid pumping; the cleaning of a piece of dirty road, and perhaps the corduroying of it, are all chances to shave costs.

The roads you grade or clean may have been the cause of a general haulage lag. Perhaps the dip you drain was frequently flooded, and that may have washed the oil out of the axle boxes of the cars, making them run hard and thus lowering your tonnage.

Your predecessor probably met these troubles by "hollering"—a cure for low production as effective as an Indian's cure for low pulse. But you're no copper-skinned medicine man and it's better to solve your problems like a man of intelligence and practical training.

However, don't try to remedy all faults at once. Correct the glaring things first, and endeavor to select and rectify those evils which, when corrected, will return the principal in 7 to 14 days. You wouldn't loan money at 25 per cent., if you could get 50.

In the second fortnight, it's possible to tackle jobs you couldn't touch in the first two weeks, because doing them would have boosted the cost of coal. But, having made a first economy that now earns for you without further expenditure, it is expedient to make slower-paying, but no less important, investments.

One word more—don't let your cost of coal go down too low till the necessary improvements have been effected, till it is certain your mine is safe within the law, and until you are sure the low cost can be maintained.

Running a mine is a long-distance event, and the fellow who winds himself on the getaway, won't even be able to walk across the finish tape. Don't try to start by making a record, and later have to increase operating charges to keep the mine in condition. When you start breaking records in the matter of cost per-ton, be sure it is downward and not skyward.

An Illinois City Coal Mining Plant

By E. F. Mullin*

Favorably located in the heart of a large city, this mine outgrew its old equipment, and recently the owners built a new, fireproof surface plant of 3000 tons daily capacity. The design, construction and operation of this plant are described in detail.

Few of the larger cities in this country can claim, as one of their home industries, an uptodate coal-mining plant, equipped to handle a daily output of 3000 tons of prepared coal. Springfield, Illinois, however, has the distinction of having within its limits such a mining operation, the property of the Capital Coal Company, which started mining about thirty years ago and has steadilv grown until now one of the leading operators in the Illinois field.

The location of the mine from a commercial standpoint is ideal, it being practically in the heart of a large and growing city, whose citizens use a large portion of the mine's output at retail prices, while three railroads, together with an interurban traction line, carry the balance to their respective markets.

The city not only offers a ready market for the coal, but also extends to employees of the company social and educational advantages seldom found in the mining towns and districts of this country and the result is, an organization of miners, who are thrifty and industrious citizens, many owning their own homes and educating their children in lines other than that of "digging coal."

Under these favorable conditions, the demand for coal from this mine gradually grew, until the company's original surface plant became inadequate for the economical handling of its output and, early in the spring of 1910, the directors decided to replace their old wooden tipple and headframe with a steel structure, equipped with the latest type of machinery for preparing Illinois coal.

General Construction

It was the company's intention at that time to continue to use its old wooden rescreen house and wagon bin; but about the time it closed the contract for the new tipple and headframe, a fire broke out, completely destroying the rescreen house and wagon bins, as well as the power plant, headframe and tipple. This brought about an immediate decision to rebuild the entire surface equipment using a form of construction as nearly fireproof as possible, and resulted in the installation of a plant consisting of steel headframe and cages, steel tipple, steel wagon bin, steel rescreen house and bin, and brick power-

Fig. 1. View Showing Rescreen House and Wagon Bin

*Columbus, Ohio.

plant buildings designed and built by the Jeffrey Manufacturing Company, of Columbus, Ohio.

A plan of the surface layout is shown in Fig. 5, as far as the limits of the drawing will permit. The office building, shops, and connections of the tipple tracks to the main tracks of the traction and railroad lines are not shown.

Three photographic views are shown, in Figs. 1, 2 and 3. The completed headframe and tipple are seen in the foreground of Fig. 2, with the rescreen house and bin in the rear. Fig. 1 shows a photographic view of the plant taken from the side opposite to that of the view shown in Fig. 2. The rescreen bin and wagon bin are in the foreground, and the headframe and tipple are seen in the rear.

The headframe, tipple and wagon bin, all under construction, are shown in Fig. 3. The construction of the rescreen house and bin had not been started at the time this view was taken.

Fig. 2. View Showing Headframe and Tipple

A City Coal-mining Plant

A longitudinal view of the tipple and an end view of the wagon bin are given in Figs. 4 and 6, respectively.

This new equipment was put into operation early this year and will hoist, screen and handle 300 tons per hour. During the past winter, it was not an unusual thing to see 50 to 60 wagons waiting their turn to be loaded with coal for the local domestic trade, which, on some days, aggregated 700 to 900 tons, the arrangement of bins and loading facilities making it possible to easily handle this amount per day.

The shaft is 10x13 ft. and has two compartments for the use of balanced hoists. There are three loading tracks passing under the tipple, two of which also pass under the rescreen bin. The lump-coal track is provided with a track scale located below the tipple and opposite the rescreen bin.

Headframe and Cages

The headframe is of steel construction, supported on four columns, and towering about 90 ft. above the rail. The engine or back brace runs parallel to the loading tracks and is provided with a stairway leading from ground to the sheave room, together with a walkway from the latter to the weigh room in the tipple, as shown in Fig. 2. The headframe is equipped with two extra-heavy 72-in. bicycle-type head sheaves, grooved to take 1¼-in. hoisting rope. The sheaves are housed over with a steel frame covered with galvanized corrugated iron. Steel trolley beams are provided in order to facilitate the handling of the head sheaves and accompanying parts.

The cages are of the two-way self-dumping type, capable of handling cars weighing, rock loaded, 8000 lb. They are constructed of wood and steel and especially designed to dump two ways, in order to provide a means of handling the rock brought from the mine.

These cages are provided with double rocker and double dumping shafts so that by the interchanging of a pin, the cages will dump either right or left. The rock cars dump to the right of the headframe as seen in Fig. 2 into a small rock bin not shown in this view.

Steel Tipple

A longitudinal section of the tipple, showing arrangement of scales, chutes, screens, etc., is given in Fig. 4. The self-dumping cages automatically discharge the two-ton coal cars into a chute leading to the weigh hopper *B*. This hopper will hold something over two cars of coal and is suspended from a five-ton scale-beam frame. The scale is equipped with a quick-weighing dial, located in the beam box *A*. The weigh hopper is fitted with a swing gate, operated by toggles through levers from the scale-room floor.

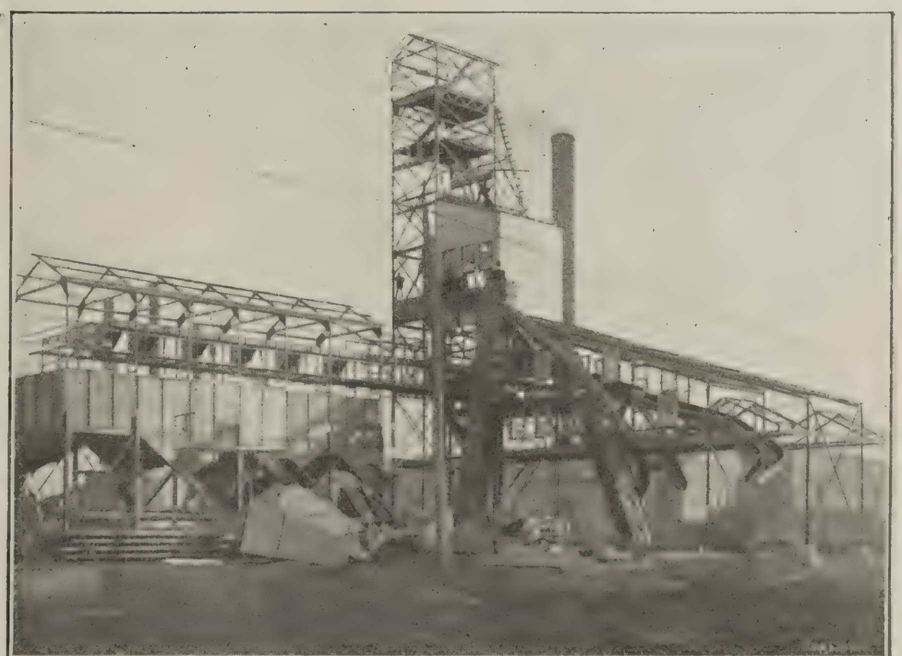

Fig. 3. View of Plant During Construction

The coal is discharged from the weigh hopper into a reciprocating feeder *C* which is of a special design, being arranged to feed the coal either of two ways by changing a valve located at

the center of the feeder plate. Coal may be fed regularly to conveyer *I* (described later) or to the upper shaking screen *D*.

This screen *D* measures 7 ft. by 22 ft. 6 in. and is provided with 16 lin. ft. of 1¼-in. round perforated plate, arranged in steps of 4 in. every 4 ft., in order to turn the coal while in transit and thus give better screening results. The lower deck of this screen is of plain steel plate, and the slack passing through the screen perforations is carried on this deck to a valve at the lower end whence it falls into chute *H*, delivering to the slack car or, if desired, is bypassed to elevator *M*.

Coal passing over the upper deck of screen *D* is delivered to screen *E*. This measures 7x26 ft. and is provided with two decks similar to those of screen *D*. The upper deck has 12 lin. ft. of plate with 3½x2½-in. oblong perforations, and the egg coal passing through these perforations is delivered into chute *G* leading to the car or, if desired, is bypassed to elevator *M*.

The lump coal passing over screen *E* is carried around the radial chute *F* to the cars. This chute is provided with loading fingers and suspended at its lower end from a hoist in order to vary the pitch for loading lump and run-of-mine product. Screens *D* and *E* are designed to deliver run-of-mine coal to the lump track without the use of veils for covering the screen plates, a feature which will appeal to many tipple "bosses" because of the simplicity of operation, it being necessary to merely close the valves in the lower decks of the screens when shipping run-of-mine.

The shaker screens are driven by a 25-h.p. motor through two belt reductions, their eccentric shaft running at 100 r.p.m. The eccentrics have a 6-in. stroke and are designed to eliminate as far as possible the heating, due to constant service and the tendency to get out of line.

Lump-coal Conveyer

Conveyer *I* is of the scraper type, with flights carried by two strands of chain. The run-of-mine coal from the reciprocating feeder is delivered to the upper strand of the conveyer, and at the loading point there is inserted in the conveyer trough a 14-ft. section of adjustable screen bars for taking out the fine coal. The screenings, passing through, are carried back on the lower strand of the conveyer and delivered into chute *N* leading to the elevator *J*. The lump coal carried beyond the screen on the upper strand of the conveyer is delivered to the wagon bin, as indicated in the photographic view, Fig. 3.

The elevator *J* handles the fine coal from the chute *N*, and also the screenings delivered by the screw conveyers from the wagon-bin chutes. This elevator has a lift of about 44 ft., is of the continuous-bucket type, runs at 150 ft. per minute, and is capable of handling 135 tons of coal per hour. It discharges into chute *L*, leading to the screen *D*, or by means of a valve, to chute *K* leading to elevator *M*. The reciprocating feeder *C*, conveyer *I* and elevator *J* are driven by a 40-h.p. motor through belt, chain and gear reductions, friction clutches being provided for all units.

The steel framework of the tipple is made independent of the headframe, in order to eliminate the transmission of vibrations from the shakers to the latter structure. The tipple's roof and siding are of galvanized corrugated iron.

Wagon Bin

The wagon bin shown in Fig. 5 measures 18x58 ft. in plan and has a capacity of 325 tons. This bin is kept full at all times to meet the demands of the local trade. The distributing conveyer *I* is carried along the top of the bin and is housed in by a steel framing covered with corrugated iron. The bin proper is supported on ten columns, its sides being of the girder type. The distributing conveyer has six delivery points in the bin, five of which are provided with rack-and-pinion valves operated from a walkway alongside of the conveyer.

The method of loading coal into retail wagons is shown plainly in Fig. 6. The bin is provided with four loading chutes on each side and these chutes are each fitted with flanged lip screens for removing the slack coal. The ends of the loading chutes are provided with manipulating devices for governing the flow of coal into the wagons. Slack passing

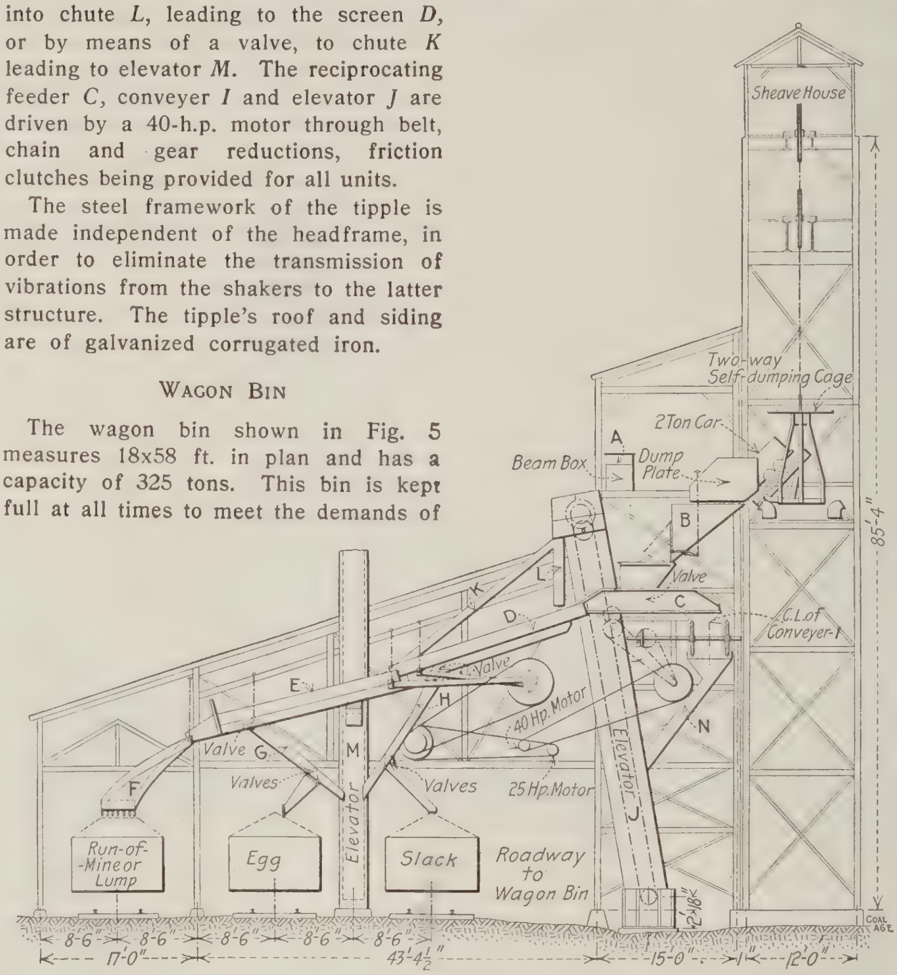

Fig. 4. Longitudinal Elevation of Tipple

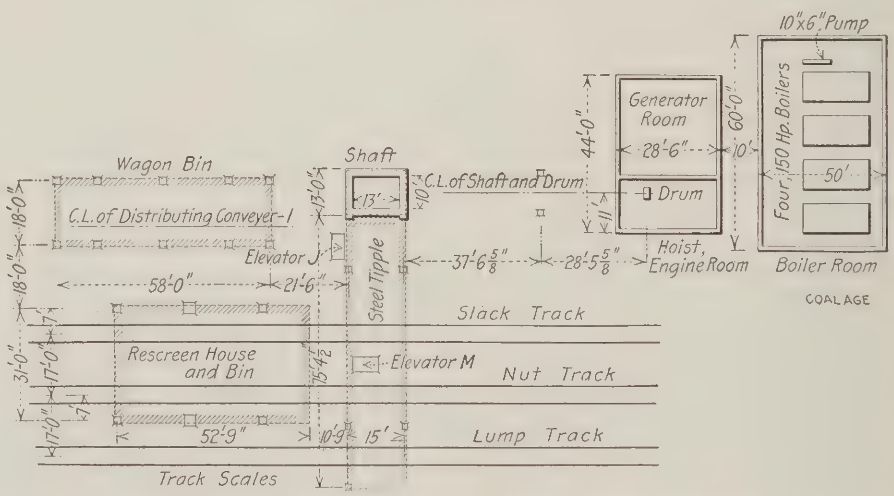

Fig. 5. Plan Showing Surface Arrangement of Plant

through the lip screens is gathered into small hoppers and discharged into a longitudinal system of screw conveyers, which deliver into elevator *J* at the tipple.

Rescreen House and Bin

A rescreen system of some kind is an essential part of a modern Illinois mining plant. The Capital Coal Company, realizing its importance, decided on a revolving-screen type of plant with a bin of sufficient size to store coal up to the capacity of at least eight railroad gondolas. The house and bin shown in Figs. 1 and 2, and also indicated in the plan, Fig. 5, is a steel structure 31 ft. wide by 40 ft. long, with a capacity of 400 tons, supported on six columns, housed over with a steel framing covered with corrugated iron, and equipped with windows and louvers.

The coal which passes through the perforations in the tipple shaker screens can be loaded into elevator *M* and ele-

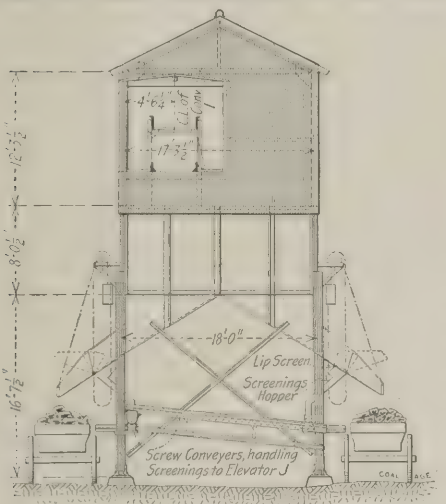

Fig. 6. End Elevation of Wagon Bin

vated to the revolving screen. Elevator *M* is of the inclined continuous-bucket type, running at 100 ft. per min. and capable of handling 135 tons per hour. The revolving screen is 6 ft. in diameter by 28 ft. long, extends longitudinally with the bin and is carried by three cast-steel friction rings running on roller shafts. The first section of the screen is covered with $\frac{7}{16}$-in. mesh wire cloth, the second section with $1\frac{1}{4}$-in. mesh and the third section with $2\frac{1}{4}$-in. mesh. This arrangement gives a grading of coal which meets the market requirements.

The bin is divided into eight compartments, giving a storage of 50 tons each. Each compartment terminates, over the center line of the loading tracks, in hinged chutes provided with chop gates for feeding to the cars. The side of the bin adjacent to the wagon bin is equipped with side-loading chutes, for serving wagons with any of the four graded sizes stored in the bin.

Elevator *M* and the revolving screen are driven by a 40-h.p. motor through belt and gear reductions. The motor is housed separately, as a safeguard against fire, just below the overhanging portion of the screen house indicated in Fig. 2. A stairway leads from the tipple floor, alongside of elevator *M*, to the motor room, and a ladder is provided from the motor floor to the screen room.

Power Plant

The power plant consists of two buildings as shown in Fig. 5. Both buildings have 12-in. brick walls with fireproof roofs. The boiler house is 49 ft. wide by 60 ft. long; it is equipped with four 150-h.p. boilers, built by the Springfield Boiler and Manufacturing Company. The engine and generator room is 28 ft. 6 in. by 44 ft.; it is equipped with an 18x36-in. Danville Hoisting Engine Company's hoist.

A 175-kw. generator, 250 volts, direct current, furnishes power for the tipple motors. The generator is direct connected to a Ridgway engine.

Organizing Rescue Work in Mines

The report of the committee appointed last October "to frame proposals for the making of an order or orders under the Mine Accidents (Rescue and Aid) Act, 1910," has been made. It is proposed that unauthorized persons shall not be allowed to enter a mine after an explosion of firedamp or coal dust, or after the occurrence of a fire, for the purpose of engaging in rescue work.

Competent rescue brigades must be organized and maintained at every mine on the following scale: one brigade where the underground workers number less than 250; two brigades where more than 250 or less than 500; three brigades where more than 500 and less than 800; four brigades where more than 800. This provision will be deemed to have been complied with where less than 100 underground employees are engaged, when the privilege is acquired of calling for a brigade from a central rescue station. Furthermore, one clause of the proposed regulations empowers the Secretary of State to exempt such a mine from this order if it is so situated that the organization of a central rescue station from which it could be served is impracticable.

Organization of Rescue Brigades

Rescue brigades must consist of not less than five persons employed at the mine, carefully selected on account of their knowledge of underground conditions, coolness and powers of endurance and certified to be medically fit.

Members of brigades must be instructed in the reading of mine plans, in the properties and detection of poisonous or inflammable gases and in the use of the various rescue appliances. Each brigade is to have a captain selected from its ranks. Members of brigades must undergo a systematic course of training, and arrangements are to be made at the mines for summoning the brigades, as soon as their services are required.

In the event of failure to organize the requisite brigades, by reason of the necessary number of underground workers declining to act in that capacity, the owner, agent, or manager of the mine shall be penalized in no way, provided he has afforded every opportunity for organization and made a bona fide attempt to arrange for the supply from a central rescue station of such rescue brigades as he is unable to provide at the mine.

Portable breathing apparatus in the proportion of two sets to each brigade are to be maintained at every mine, and the apparatus must be capable of enabling the wearer to remain for at least one hour in an irrespirable atmosphere. This provision is to be considered as complied with when the privilege is acquired of calling for such appliances from a central rescue station, if the latter is not more than 10 miles distant and connected by telephone with the mine.

It is required that there shall be provided and maintained at every mine: 1. Two or more small birds or mice for testing for carbon monoxide. 2. Two electric hand lamps for each brigade, ready for use and capable of giving light for at least four hours. 3. A safety lamp for each member of the brigade for testing for firedamp. 4. Tracings of the workings which have been brought uptodate within not more than three months, showing the ventilation courses and all doors, stoppings, etc., and distinguishing the intake air from the return air by the use of a different color of ink.

Equipment of Central Rescue Station

At each central rescue station, not less than 15 complete sets of apparatus are to be maintained, with means of supplying sufficient oxygen or liquid air to enable this apparatus to be used constantly for two days and with the necessary means of charging such apparatus. Twenty electric hand lamps, four sets of oxygen reviving apparatus, ambulance boxes, together with antiseptic solution and fresh drinking water; cages of birds and mice, and a motor car are to be in constant readiness.

Rules for the conduct and guidance of persons employed in rescue work, such as may appear best calculated for the carrying out of rescue operations, must also be formulated and kept at every mine.

Stone Dust in Mine Explosions

By R. Dawson Hall

Stone dust as an immunizing agent against explosions has many important properties which should be considered in addition to its merely nonbituminous nature and quantitative presence. Its density, chemical composition and conductivity, the size and shape of the particles, the specific heat and temperature of dessication are all factors to be taken into account.

In a letter, published on Jan. 21 of the present year in *The Engineering and Mining Journal,* I commented on the action of air-borne bodies when stopped by the interposition of a diaphragm or by the reverse action of an incipient explosive discharge or "blownout" shot. I attempted to show that these air-sustained bodies, because they were traveling with equal velocity and had greater density and consequently greater momentum than the medium in which they traveled, continued on their way after the air ceased to advance. Thus these dusts and other solids approached the diaphragm, explosive discharge or "blownout" shot closer than the air in which they were severally traveling and thus aggregated in larger percentage near the disturbing factor.

Mechanics of Immunization

Seeing that "stone dust," as all nonbituminous dust is misleadingly termed, has a density about 1.8 times greater than the dust of pure coal, it is a justifiable inference to assume that, other things being equal, the stone dust will advance toward the disturbance further than the coal dust. The word "advance" here and hereinafter is used relatively and means an advance, a slower retardation or a retarded change in direction.

But this advance may be assumed, also, to be favored or resisted by the nature of the dust, a cuboidal dust being more readily stopped than a spherical, and a spherical dust being less persistent in travel than one which is lenticular and with more spread in a horizontal plane than in a vertical. A thin scaling shale dust in this manner resembles an aëroplane, easily sustained, but freely traveling against a suddenly opposing wind by virtue of its own previously acquired momentum.

It is to be assumed, furthermore, from a consideration of the laws of nature and from observation of the action of a hurricane, that the longest dimension of any body propelled by a medium is in the direction of the flow of that medium, granted that the body be free to turn and also that the next largest dimension is so disposed horizontally as to resist most the possibilities of falling under the influence of gravity.

Immunizers in Mine and in Laboratory

Consequently, from a laboratory standpoint, the best dust for immunizing a gallery from explosion is a dust of a flat, multi-stratified, aëroplanic nature, not only well ground but well weathered into thin flakes, easy for swirling air currents to pick up, able to travel with minimum resistance, dense enough to project itself freely through the enveloping air into the very forefront of the disturbance, and free of any bituminous content which might aid an explosion. These are the primary desiderata, mostly mechanical, of a pulverized stone for use in an explosion gallery for immunization.

But a truer theory, embracing the conditions found in a working mine, would suggest that a dust, which will cement well with the coal particles on the floor of the mine to form a hard pavement, resisting disintegration and the elevation of its material by the air, will be better suited to produce immunization than a dust of so dry a nature that it has not enough cementing value to render that floor coal dust innocuous, even under continued travel.

The shape of coal particles is cuboidal, of sandstone, spherical and of shale, mostly lenticular. Consequently most forms of stone dust are of such shapes that they travel further than most forms of coal dust when projected.

Moreover, not only are stone dusts projected further by reason of their shape but they are also raised more freely than their relative densities as compared with that of coal would indicate.

Thermic and Thermochemic Considerations

There are some other considerations. A lenticular dust will be more readily heated than one which is either cuboidal or spherical, especially the latter; consequently it will have more power to lower the temperature of incipient explosion.

Most stone dusts have a large quantity of combined moisture in their composition while others contain carbon dioxide, which is driven off at and below a red heat. This makes their power to lower the temperature of an explosion far greater than a mere consideration of their specific heats would indicate. Where carbon dioxide is given off, it must tend to prevent combustion of the coal dust. Shale dust and clay dust lead among the hydrated bodies and may be looked upon almost as "tabloid" forms of water. A rich clay may easily contain as much combined moisture per pound of clay as will be found in saturated air per pound of suspended coal dust. Sandstone dust contains but little combined water; what there is, being contained in the hydrated reconstructions of its original cements. It is hardly permissible to call attention to the obvious fact that dehydration and decarbonization will proceed more rapidly, if the dust be fine or lenticular, than if in any other condition.

Sensible Heat of Stone Dust Inconsequential

But to show the inadequacy of the specific heat to explain the whole caloric absorption of a heated dust of clay or shale, the following calculations are made:

Suppose the dust chosen, to have a specific heat of 0.2 and that this value is correct between temperatures of 32 deg. and 3632 deg. F., a range of 3600 deg. A pound of such dust heated to the upper limit would absorb 720 British thermal units.

Suppose that the chemical composition of the pound of dust is represented by the formula $Al_2O_3\ 2SiO_2\ 2H_2O$, which would give 0.139095 lb. of combined moisture and 0.860905 lb. of residuum after heating and complete dehydration. Assuming that this residuum has a mean specific heat of 0.2 in the aforementioned interval of temperature, the number of British thermal units stored up in it will equal:

$$0.2 \times 0.860905 \times 3600 = 619.85 \textit{ B.t.u.}$$

Taking Mallard et Le Chatelier's figure for the average specific heat between 32 deg. and 3632 deg. F., namely, 1.22, instead of Rankine's value in the formula for the total heat of superheated steam, we have $0.139095\ (1092 + 1.22 \times 3600) = 1047.17$ B.t.u. Adding this to the units of heat absorbed by the residuum as calculated above, viz., 619.85 B.t.u., we have 1667.02 units, which result is 2.32 times higher than was obtained by assuming an even caloric adsorption of 0.2 unit per degree of rise of temperature for the undecomposed body.

The specific heat of steam I have quoted appears large and it is probable that is not truly a specific heat at all but a combination of that heat with heats of partial isomerism or dissociation. Perhaps this will account for the differences between Mallard et Le Chatelier, Berthelot et Vieılle and D. L. Chapman, the interatomic changes possibly not being equally marked in the course of their several examinations. The Berthelot value would be 1.62 and the Chapman value but 0.87 instead of 1.22 as given for the specific heat used above and based on Mallard et Le Chatelier. This conjecture relative to the cause of the discrepancy in results is perhaps unwarranted, and may well be due to methods in measurement rather than to true differences of heat adsorption.

But to Berthelot must be credited the other statement that the so called specific heat (*chaleur spécifique*) is not a simple quantity, but a compound of the true specific heat with the heat demanded by "that work of molecular loosening of the compound gas which produces no change in its composition and also the further work of dissociation, that is to say, of decomposition, properly speaking (*travail de désagregation moleculaire du gaz composé, sans changement dans sa composition chimique et le travail même de dissociation, c'est à dire de décomposition proprement dite*)".

Heat of Combination of Stone Dust

But the difference is far greater than thus set forth, for a large number of units of heat may be expended in producing a separation of the combined water from the slate or clay. I have never seen this quantity determined but any brickmaker will declare that the hold of clay and shale on the water of constitution is very strong.

It has been objected that in the length of time that an explosion lasts, there could be no such change of condition, that it would take an appreciable time for the dehydration of clay and the "burning" of limestone. Still less could such a change occur in time to prevent a blownout shot or flaring-up of methane from developing into a violent explosion.

It has been found, however, that in the spectrum of an explosion in a test tube, the lines of sodium made their appearance, showing that despite the short duration of its action, the glass was in a degree resolved into its component parts. It would be feeble in view of the uncertainty with which the rapidity of decomposition can be forecasted to say at what speed heat of great intensity will act on clay and limestone, but the fact just given is at least suggestive that the temperature of an explosion may almost instantaneously resolve some compounds into their major constituent parts.

The readiness to heat and the large amount of dehydration and decarbonization must lower the temperature of incipient explosions, while the mobility of stone dusts due to their shapes and densities must serve, it would seem, to increase considerably their percentage at the vital points.

When M. Taffanel speaks of a 50 per cent. admixture of stone dust with coal dust it is an essential point to remember what are the shapes, sizes, specific heats, conductivities, degrees of hydration and temperatures of desiccation of his stone dusts, together with the firmness of the bond with which those combined moistures are retained, and to duly consider that he does not refer to their actual distribution in the explosion zone, but to their quantitative presence on the floor and sides of his explosion gallery—quite a different matter.

That the action of dehydration in cooling flames has received some recognition is shown by the fact that alum is used, or has been used, for that purpose in the manufacture of explosives. Potash alum, it is true, has 45.52 per cent. of water of crystallization in its composition, whereas the percentage in pure clay of the water of constitution is only 14 and of gypsum 20.91 per cent.

Vancouver Island Coal

According to Consul Abraham E. Smith, a Canadian geological survey report states that the bituminous coalfields of Vancouver island are the largest on the Pacific coast. The coal area of the island is divided into five fields, viz., Nanaimo, Comox, Suquash, Cowichan and Quatsino. Of these, the Nanaimo field, with an area of 350 square miles and a content of 1,344,000,000 tons, is most important. Last year the Nanaimo field produced 1,615,160 tons of coal.

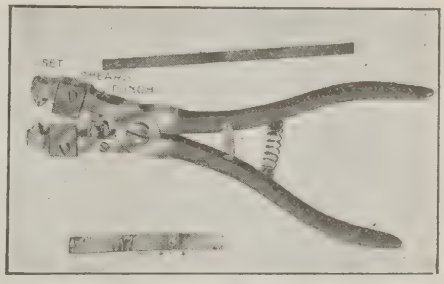
Comox is reported to have an area of 300 square miles, and the same thickness of coal as Nanaimo, making its content 1,152,000,000 tons. Suquash is given an area of 10 square miles, with an average thickness of 3 ft. of coal, or 19,000,000 tons. Recent development shows this field to have two seams of economic value, hitherto unknown, while diamond drilling shows the coal area to be probably six times greater than previous estimate, both in area and content. The Cowichan field is placed at an area of 9 square miles, averaging 4 ft. of coal, or 23,000,000 tons. The Quatsino field is placed at 5 square miles, with an average thickness of 3 ft. of coal, or 9,000,000 tons. The Cowichan and Quatsino fields are the only two lying dormant.

Alberni is likely to be added as a new field. It has long been recognized as probable that coal might be found in Alberni, outliers of the Comox formation having been recognized there. When a railway extension was under construction last fall the steam shovel uncovered a seam of coal, and the company recently started development, with the result that, so far as the slope has been run, about 170 ft., a continuous seam of coal of high quality and of a thickness of 4 ft. has been proved up. From the evidence now available it seems probable that the coal areas of Vancouver island are good for about 3,000,000,000 tons of coal, or enough to supply 10,000 tons a day for 800 years. The Vancouver island coalfields have produced to date coal to the value of $70,000,000.

The yield of the Vancouver island coal mines during the calendar year 1910 is officially reported as 1,616,030 tons, produced by four companies.

Steel Tape Repair Outfit

The accompanying halftone shows a new tape-repairing outfit, somewhat similar to others but embodying a few additional conveniences.



The tool is small, light and durable, and with an extra piece of tape and rivets, repairs are easily made. The punch will cut two thicknesses of the Lufkin or Chesterman tapes or one thickness of heavy chain type. This tool is made by the Pittsburg Instrument and Machine Company, Pittsburg, Penn.

Bath Tubs for Mules

The Philadelphia & Reading Coal and Iron Company is installing for the use of their mules, large concrete bath tanks sunk in the ground of the stable yard scaling 4 ft. deep, 6 ft. wide and 37½ ft. long. A 6-ft shower is arranged to play on the body and head of the mule so as to complete the cleansing. The approaches and floor are corrugated to protect the mule from slipping. The tanks are heated in the winter by a jet of steam. Mr. Newhard, chief veterinarian, is the originator of this improvement.

Hard Running Cars

At some mines, perforated piping is installed to spray the car wheels and tracks on insufficient grades near the tipple, so as to decrease the rolling resistance of the cars and reduce the necessary hand or animal power required to move them. This cleansing action works very well during the summer but in the winter, when cars run still more stiffly, such assistance is not available. It is at best a summer day's makeshift.

Power from Coke Oven Gases

By C. A. Tupper*

The waste gases from beehive and byproduct coke ovens are being extensively used abroad for generating power, but go largely unrecovered in this country. They may be burned under steam boilers or used directly in gas engines.

In European countries the utilization of coke-oven gases for power generation has long been common practice. The earliest method, and the only one commercially feasible with the old beehive or improved Belgian ovens, involves the use of the gases under boilers for producing steam. This is accomplished in the simplest manner by constructing a large flue parallel to the rows of ovens and providing communication from near the top of each oven, the connection being controlled by means of suitable dampers. Through this main flue the gases are conducted directly to the boiler house. In estimating the power to be obtained, the average is taken as 15 to 20 h.p. per oven, depending upon its size and the quantity of volatile matter contained in the coal.

With such an arrangement, while the ovens are in service, no coal need be used for generating the power required at a coking operation, other than that which is being treated; and the only charge for fuel is represented by the investment in the flues, their depreciation, etc. Also the expenses of handling fuel, which amount to a considerable item during the year, even when the fuel itself as mine waste can be secured at little or no purchase cost, are eliminated.

Experience with this method has been quite satisfactory, not only abroad, but also in the United States wherever it has been tried; and, if merely a small amount of power is needed, or its use is intermittent, such a plant is to be recommended, for various reasons, in preference to the more costly equipment for gas-engine operation described below. The principal difficulties arising heretofore have been due either to excessively lean gases, fit for nothing more than utilization in economizers or regenerators, or to deterioration of the flues as the result of extreme heat. The latter has also been accompanied by warping or melting of the dampers, both in the main flue and the feeders, even as far as the boiler house. All such troubles can, however, be remedied by proper design and construction and the use of suitable materials.

Use of Gases from Byproduct Ovens

Where byproduct ovens, such as the Koppers, Otto Hoffman or Semet-Solvay, are used, the installations made in the same vicinity usually include mechanical equipment for other extensive operations, such as mining, iron and steel making, etc., and the erection of a large central power plant becomes a matter of economy. Therefore, a heavy initial investment, if wisely planned, may effect a

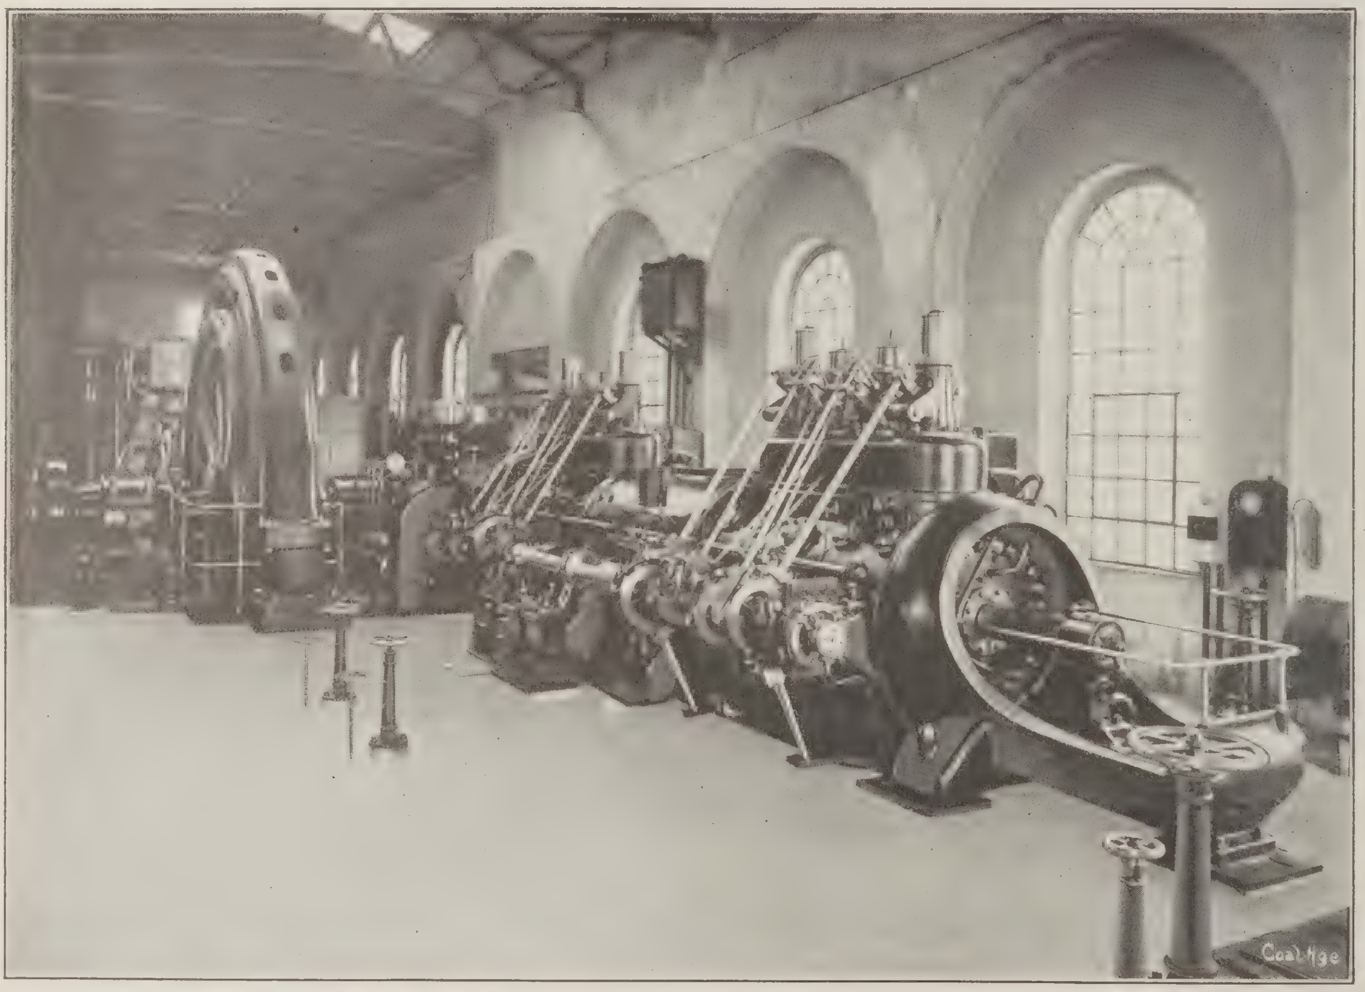


Fig. 1. Gas Engine of 1000 Horsepower, Using Coke-oven Gas, Brambauer, Germany

*Milwaukee, Wis.

material reduction in running costs, particularly as the gases from byproduct ovens can be utilized, after cleaning, directly in gas engines, thus securing a much higher thermal efficiency than is possible under boilers. The gases from a byproduct oven are, of course, much richer and more suitable for this purpose than the hot gases from one of the beehive type.

Now, assuming that a ton of coal, as charged, gives 9900 cu. ft. of gas, which is a fair average, and that from 60 to 65 per cent. is needed for heating the ovens, there will be available for power generation a minimum of 3465 cu. ft., a figure which is often exceeded in practice. Experience shows that this yields 5½ to 6 h.p. for each ton coked per day of 24 hours continuous operation.

In the cleansing of coke-oven gas it is necessary to remove both the various tar products which it carries in suspension and the more intimate mixtures of sulphur and cyanogen compounds commonly found in such gas.

Evil Effects of Tar and Sulphur in the Gases

The tar products, if not thoroughly removed, are the principal cause of fouling the induction parts and valves of a gas engine, as well as its cylinder, and frequently cause premature ignition, sticking of the regulating mechanism, etc., while all sulphur compounds that reach the cylinders turn into sulphurous acid during combustion, are converted into sulphuric acid by contact with moisture and rapidly eat away the eduction parts. Since it is necessary to use water in cooling and muffling, there is always danger of destroying vital parts of the mechanism if the sulphureted hydrogen is not prevented from entering.

The tar products which the gas carries in the form of vapor are, of course, pretty thoroughly removed in a modern byproducts plant, or may be otherwise separated by any acceleration in the cooling of the gas; but a residue remains which must be caught and retained in suitable tar washers, of which a number of satisfactory types have been evolved.

The separation of the sulphur and cyanogen compounds is considerably more difficult but, at the same time, far more important. In illustration of their destructive power, reference has been made above to sulphurous acid, which, as sulphureted hydrogen, is the commonest compound; but there is also sulphide of carbon, occurring in smaller quantities and presenting greater difficulties in its removal, and the cyanogen compounds, which form prussic acid during combustion and also act destructively on all mechanical parts subject to contact with them.

Several different methods of purification have been brought out in Germany; and in the accompanying sketch, Fig. 2, is shown one of the most successful of these plants for cleansing coke-oven gas. This was designed for use with a gas engine of 1000 h.p., supplied by Haniel and Lueg, of Düsseldorf, for the Gerkschaft Minister Achenbach (Minister Achenbach Colliery), with mines and ovens located at Brambauer, near Dortmund, in Westphalia, Prussia. A photograph of this engine is shown in Fig. 1.

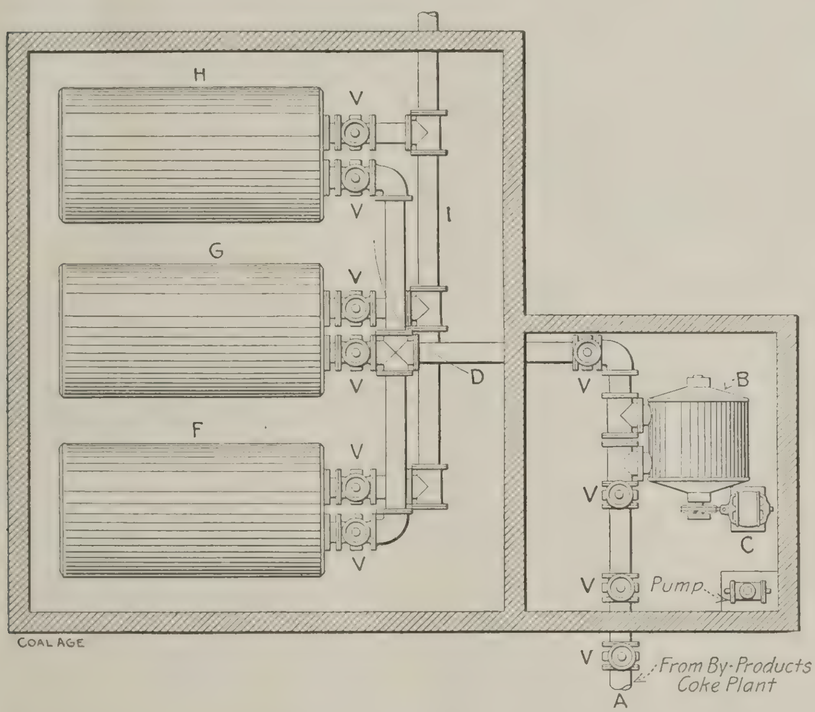

Fig. 2. Purifying Plant

From the theoretical standpoint this sounds well. In practice, however, its value has often been minimized or destroyed by failure to observe one of the fundamental conditions of utilizing waste gases for internal-combustion engines, which is the installation of an efficient cleaning plant. To insure continuous operation, the purification of the gas is a primal necessity, for, since the gas is admitted directly into the engine cylinders, all the noncombustible elements, which would remain in the cylinders and clog them or erode their surfaces, must be carefully eliminated. Such precaution becomes of especial importance when the engines are required to operate continuously and there is little or no opportunity for shutdowns to clean the cylinders.

Gas-purifying Plant

In Fig. 2, *A* represents the large gas main leading from the byproducts coke plant which the company operates, and *B* is a cylindrical rotary washer, of the Zschocke type, where the tar elements are thoroughly separated, together with the residue of ammonia not recovered in the main works. At *C* may be seen the alternating-current motor which, by means of reduction gearing, drives the washer. Through main *D* the gas, which is then charged only with compounds of sulphur and cyanogen, passes to feeders under the wrought-iron tanks *F*, *G* and *H*, where, by means of suitable vents, it is evenly diffused.

In these tanks bog iron ore is spread out on wooden hurdles, or wicker frames. In rising, the gas comes in contact with the ore, so that sulphides and ferrocyanide are formed, completely removing all noxious chemical elements. The purified gas then flows through the main *I* to the gas holder.

It is stated by the colliery officials that, after runs of two to three months or more, "no fouling worth mentioning" has been found in the cylinders or valve chambers of the engine, and there has been no clogging of the gears, thus demonstrating that the cleansing plant does the work for which it was designed. The layers of ore are automatically shifted, during operation, so as to regenerate them by exposure of their surfaces to the air; an oxidizing process then takes place, and the tanks can thus be used continuously until the mass is completely saturated. In practice it is usual to have two in service while the third is being recharged.

The matter of dust in suspension does not enter seriously into the problem of purification, as it previously settles or is removed during the recovery of the byproducts, but any which the gas may still contain is caught by the rotary washer, *B*.

High Thermal Efficiency

It has been the experience of Messrs. Haniel and Lueg, mentioned above, that, with the use of gas engines and a suitable purification plant, the waste gases from byproduct ovens will yield nearly double the thermal efficiency, for power purposes, that they would if utilized to generate steam. The idea is one that has been extensively applied in Germany and other countries of Europe but has thus far made little, if any, headway in the United States.

This is probably owing partly to the fact that the principal byproduct ovens are situated in or near large cities, where the gas can be sold for illuminating and heating, and partly to their location, more recently, adjacent to steel mills or other large works where the plan of the power equipment was decided upon previous to their erection. However, the increasing opportunities for the profitable application or sale of electric power, and the extension of coking operations to new districts, will render the subject one well worth studying for the future.

The Coal Dump

A fall of 3 per cent., is often provided on the approach road for the mine cars to the tipple. This is somewhat excessive, but 2 per cent., where the individual cars are handled, is a minimum and 1½ per cent., where large trips are dropped forward without mechanical assistance. Where long trips are to be dropped, and where there is not sufficient available fall, the tracks should be doubled or trebled, giving the motive power an opportunity to place the cars near the tipple. This is often the better arrangement as it reduces the travel of the mine car dropper.

When the coal is fragile, the grade of the mine tracks above the tipple should be reduced to the minimum at which coal cars can just drop in all seasons of the year. When the coal is to be dumped for coke use or where the markets will buy coal with a large percentage of slack, there will be a gain in the steep grade so long as the car dump and the tipple are stout enough to resist the strain.

It is well to remember that chutes are built at the angle at which coal just slides and to save it from breakage are made no steeper. If the chutes clog they can be cleaned by hand. When the chute cannot be reached for cleaning, the grade must be increased. But no storage can be obtained where chutes are set on the angle on which coal just runs, for to store a body of it, part must travel over a bed of coal and the minimum angle of travel will be greater. Arranging for such storage, chute grades are necessarily increased and if the chutes be emptied the fall of the coal will not be without excessive breakage. Even if the chutes are full, the breakage in the storage bins will be great. Any lump of coal which stops the forward flow will have to take up much of the dynamic energy of the coal above. This is why storage chutes are not more general, apart from the difficulty in obtaining tight, easily operated doors.

Installation of Power at Collieries

Special Correspondence

In the course of a paper on "Some Considerations Affecting the Installation of Power at Collieries," read before the Mining Institute of Scotland, Frank Anslow refers to the controversy now raging as to the relative advantages of the three-phase and the direct-current systems for colliery work. He says that for all practical purposes each system is equally dangerous, or perhaps it is better to say equally safe, if properly installed under conditions suitable for the system selected. Attention should be concentrated upon the question of rendering existing installations safer. Much can be accomplished in this direction, as many of the plants are at least from 10 to 15 years old, and desirable modifications may not only afford greater safety in working, but probably result in increased economy.

The possibility of electric shock is always present no matter what system is employed, and for all practical purposes the danger is independent of voltage, as the lowest practical has been shown to be fatal. The possibility of shock can be comparatively easily eliminated in all generating, motor and other plants by earthing, with the exception of coal cutters, which are more difficult to deal with. The greatest danger of shock, however, is from the cables, including main, distribution and trailing cables. In the mines of Scotland this danger is particularly prominent, owing to the wet and low seams, the latter affording the possibility of men getting into contact with the cables. The arrangement of the cabling system is necessarily a matter depending on local conditions. Armored and unarmored cables both possess advantages, but whichever type is selected great care in the installation thereof, with constant supervision, is the essential and only safe manner of dealing with cables if fatal accidents are to be avoided.

Main Objection to Direct-current Plant

One of the main objections raised to a direct-current plant is upon the score of sparking. The improvements in the design of such a plant have resulted in practically sparkless commutation, even under severe overload conditions; however, it cannot be disputed that the danger of the ignition of gas or coal dust from this cause still exists. Mr. Anslow points out, however, that this danger is also present with alternating current slipring motors, and also in a modified degree with those of the squirrel-cage or short-circuit type.

To earth, or not to earth, is at present a great question, and there are many advocates both for and against. Too frequently, however, the problem is met by a most unhappy compromise of partial earthing. If earthing is attempted, it must be carried out effectively, and generally speaking, two main earth plates should be employed, one on the surface and one below ground in the shaft sump or other suitable position.

These two plates should be connected by a main wire, which should run the full extent of the installation, and all electric or metallic work in connection therewith should be connected to it by wires of suitable section. The alternative of a number of local earth plates is sometimes preferred, but the difficulty in this system is to obtain a good earth, and the main wire will appear to offer, on the whole, the best solution.

As Concerns Large Hoisting Plants

In dealing with large hoisting plants, Mr. Anslow points out that an equalizing system is usually necessary to reduce the demands upon the generating station or supply mains, and then he recalls that fans and pumps require motors to run them, (a) at a low or medium constant speed; (b) at a high constant speed; (c) at variable speeds. In the first case, direct or alternating-current motors are equally suitable; in the second case alternating-current motors can be more easily constructed for high speeds, and no commutation troubles are involved if squirrel-cage machines are employed. Frequently, high speed is not possible with alternating current owing to the low periodicity of the power company's supply. When variable speeds are necessary, direct-current is usually preferable, as the speed variation properties of alternating-current machines cannot be compared with those of direct current.

Direct-current coal cutters, from a working standpoint, are superior to those operated by alternating current, but the latter type has proved itself reliable and satisfactory. There is another possibility with regard to coal-cutting machinery, that is, by the use of compressed air they may be operated from an electrically-driven compressor. Such a combination affords many possible advantages, especially where a number of cutters are employed in a small area, as these can all be supplied from one compressor, thus securing the advantage of compressed-air cutters and the economy of electrical transmission.

Colliery Dwelling Construction

By A. T. Shurick

This is the second of a series of articles on miners' dwellings. In this number the foundations are discussed, and the designing and carpenter work taken up in detail.

NOTE—The first article on "Colliery Dwelling Construction" appeared Oct. 21.

The kind of foundations used is dependent on the character of the building and the extent of funds available. They may be posts, piers or walls. Posts are used only on the cheapest or more temporary structures and may be the ordinary round-prop timber used in the mine or 4x4-in. or 6x6-in. timbers. They are driven in the ground and sawed off to the required hight or may rest on a flat stone or short piece of plank acting as a mud-sill.

Piers are built of either dry- or wet-rubble masonry, brick or concrete. Dry-rubble is adaptable only for short piers consisting of one stone on top of another. When using wet-rubble and with stone of average quarrying qualities, it is not consistent with good results to construct a pier less than 20 in. square. Concrete is seldom used on work of this character, but should it prove desirable a 10-in. square pier properly reinforced with ¾-

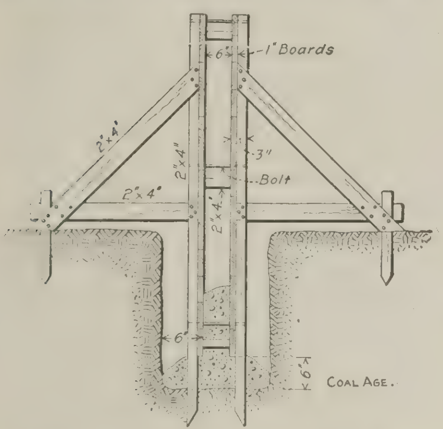

FIG. 1. FORM FOR CONCRETE WALL

in. vertical rods at each corner and resting on a spread-footing, 12-in. thick and 24-in. square, will give satisfactory results for ordinary hights. The concrete should be made soft and in the proportion of 1:2½:5, the large aggregate being sized to pass a 1-in. screen. Brick piers laid up in lime mortar give satisfactory results. On the whole piers of any kind are not good construction on work of this character as the space beneath the building will often be used as a hog-pen or made a repository for refuse, thus producing unsanitary conditions. In northern latitudes this construction leaves the bottom of the building exposed, making it cold.

A solid wall does not add materially to the cost of the building, considerably enhances its value and is one of the most common footings met with in this class of work. The wall may be of dry- or wet-rubble, brick or concrete. A dry wall when well put up would be amply sufficient were it not that they are being continually pulled down by the children or the miners themselves who sometimes wish to gain access to the interior. A rubble masonry wall, laid up in either lime or cement mortar, is probably the most satisfactory and on the whole the most common wall used on this work.

These walls are commonly made 18 in. thick, although with a stone that quarries well a competent mason can put up a satisfactory 16-in. wall. Headers 8 in. thick and 18 in. wide should be required

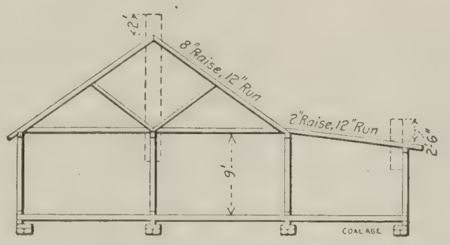

FIG. 2. METHOD OF ERECTING

every 4 ft. in length, and 3 ft. in hight, no two consecutive vertical joints should be allowed and the stone should be laid on its natural bed. The mortar used may be either lime, hydraulic lime, lime and cement or cement. A lime mortar of from 1:2 to 1:4, depending on the quality of the lime and the cleanness of the sand, will give entirely satisfactory results if the wall is allowed to season and then pointed with a 1-cement, 1-lime and 3-sand mortar. In the case of a cellar wall, hydraulic lime or cement should be used, and if the stone is soft or porous it is a good plan to give the outside a ¾-in. coat of 1:2 cement mortar.

CONCRETE FOOTINGS

Should it prove desirable to use concrete for the footing a very light wall will suffice when using a 1:2½:5 mixture of one of the standard Portland cements. When the ingredients can be placed on the ground at a moderate cost, and a portable machine mixture is available, the cost of this work will often run below that of rubble masonry.

Fig. 1 shows a method of constructing the forms for placing the concrete. They may be built of either 1-in. or 2-in. boards which should be smooth on one side and one edge, and preferably, tongued and grooved. The studs are of 2x4-in. and when using 1-in. boards they should be placed on 24-in. centers, while for 2-in. boards 5-ft. centers are sufficiently close. Forms of 2-in. boards require less labor to build, have a higher salvage value, and under average conditions are probably more economical. Struts of 2x4-in. are placed between the faces of the forms, which are then drawn up tight, either with bolts or wire; the struts are removed when the concrete reaches them, the wires left buried, and the bolts taken out after the concrete is partially set.

For the ordinary four- or five-room house, with walls not exceeding 6 ft. in hight, a thickness of 6 in. is sufficient, while for a house with an 8-ft. cellar, the

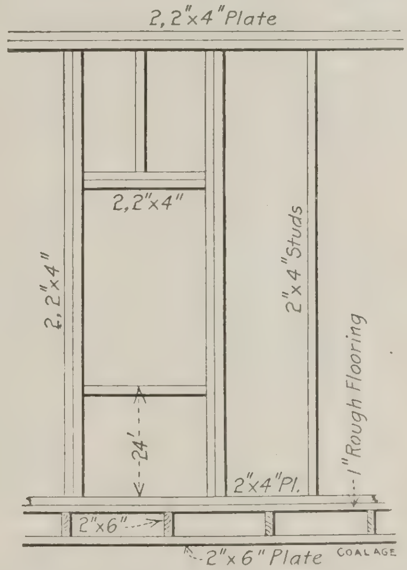

FIG. 3. WINDOW FRAMING

walls may be made 10 in. at the bottom and 8 in. at the top. To provide for freezing, the ground should be excavated 4 ft. in the Northern States, and 3 ft. in the Southern, and spread footings 18 in. wide and 6 in. thick used.

The abundance of good stones which are commonly found in the coal formations usually makes some form of stonework cheaper than brickwork, but when it may prove desirable to use the latter, a 12-in. wall, laid up in lime mortar, will suffice for the ordinary four- or five-room house.

Chimneys—The chimneys are almost entirely built of brick. The flue of the main chimney, to which two or more stoves are to be connected, should not be less than 8x8-in., while that on a lean-to addition, having usually only one stove, may be made with a 4x8-in. flue. The flue may be lined with either lime or cement mortar, preferably the latter, or the

joints may be struck with the point of a trowel; care should be taken to have the lining as smooth as possible.

Fig. 9 shows the details of an ordinary chimney for the average three- to five-room house. Since they are comparatively light they are usually supported on the partitions about 6 ft. from the floor, thus effecting an economy of this much brickwork. The walls are commonly made 4 in. thick, or the width of one brick, which provides ample stability although the efficiency of the chimney will be materially increased by having 8-in. walls. The chimney should be carried not less than 2 ft. above the building and topped off with some ornamental effect, the one shown being simple and appropriate for this type of building.

Carpenter Work

Before taking up the work of designing, the engineer should provide himself with a set of the standard rules for the grading and classification of lumber for the district in which he is located. These rules are issued by the Associated Bureau of Grades in pamphlet form and give detailed lists of defects admissible in the different grades of lumber, together with full-sized cross-sections of the various shapes and minimum dimensions. He should also have the catalog from some large factory which will give full-sized sections of different moldings, standard dimensions of doors and door frames, window sashes and frames, etc. By carefully following the catalog and specifying only stock shapes and sizes, an appreciable economy will be effected, since these details require considerable framing when of odd dimensions and can be bought much cheaper manufactured.

Frame houses may be roughly divided into two classes, braced frame and balloon construction. Braced-frame construction is a relic of former times, when mortise-and-tenon joints were cheaper than those made with nails or bolts, because of the high cost of the latter, which were all hand made. In this construction all pieces are carefully fitted into place, important joints being secured with a mortise and tenon, making a well braced and very stable structure. With balloon-frame construction, the pieces are simply nailed together and the structure depends on the sheathing for its stability. This class of construction is the one commonly used in most houses today and costs about one-half that of the braced frame.

Sills—Where masonry foundations are provided for the sills, these need not be larger than 2x6 in. They should be given a half splice at the corners and other points where necessary and set in a mortar grouting, preferably of cement; the underside is sometimes given a coat of linseed oil to prevent the absorption of moisture from the foundation. The sills should be set back 1 in. from the outside face of the foundation, which brings the sheathing even with the face, and allows the siding to extend below the sill, making a weather-tight joint.

Floor Joist—After the sills are placed the floor joist are next set, which for construction of this class, are placed even with the outside edge of the sill, as shown in Fig. 10. A better grade of construction is shown in Fig. 8, in which a boxed sill is used against which the joist butt. Since the floor joist are of rough lumber, the dimensions of which may vary one-half inch or more, they should be sized on the bottom side sufficient to bring the tops all to an even line. For the second floor joist a channel or groove should be cut in the under side to fit on the ribbon or ledger board. To eliminate the possibility of warping, the joist should be laid with the crown or convex side up, the superimposed load then tending to hold them to position.

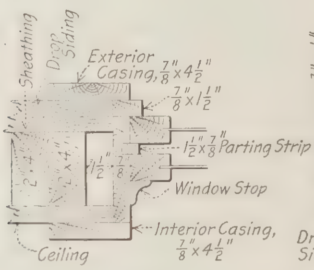
The size floor joist to be used cannot be determined from the usual tables given in the different architects' pocketbooks, since these tables are computed only for the better class of houses. Thus, for instance, in the Architects' and Builders' Pocketbook (Kidder), complete tables are given for the maximum span of floor joist for loads of from 60 to 174 lb. per sq.ft. Most of these tables are computed for a maximum deflection of 1/30 in. per foot of span, an item not usually necessary to consider on this class of work. There is, however, in the same book a series of tables for the safe quiescent loads, uniformly distributed, which may be used to advantage. In computing the permissible loads of a number of typical examples of this class of construction, it has been found the joist are designed for loads ranging from 38 to 50 lb. per sq.ft., according to the values given in these tables. Floors designed for a load of 38 lb. are commonly used and, aside from a pronounced deflection, appear to give satisfactory results.

Flooring—The use of single floors is condoned only in the very cheapest class of construction, double floors, sometimes of the poorest grade, nearly always being used. An average floor for this class of building consists of sheathing for the rough flooring and 1x4-in. or 1x6-in. Nos. 2 or 3 grade of flooring for the finished. The rough flooring should in all cases be laid at an angle of 45 deg., with the floor joist and the finish at right angles to the joist. When both floors are laid in the same direction the unequal shrinkage, due to the broader widths of the sheathing, will draw the finished floor apart. The rough flooring should be nailed at every joist with two 8-d. nails, and the finish blind nailed at each joist with a single 8-d. nail.

Because of the loss due to the tongue and groove and the difference in actual and trade dimensions, a certain percentage must be added to the amount ordered above the real superficial area to be covered. The usual practice is to add 50 per cent. for 3-in. flooring, 33 per cent. for 4-in. and 20 per cent. for 6-inch.

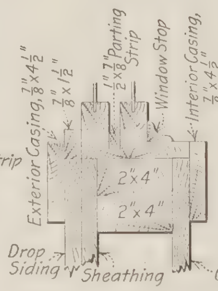
Studs—In the better grade of buildings the studs rest directly on the sills and are nailed to the floor joist, giving strong construction. The methods shown in Figs. 8 and 10, which are details of the houses described in my first article, are sufficiently strong for ordinary purposes, and more economical in materials and labor.

In this method a floor plate is laid on the rough flooring, of the same section as the studs, which provides an even bearing for the latter as well as a nailer to which the studs are spiked. The studs should be of 2x4-in. and may be placed 24 in. on centers except when the interiors are to be plastered, when they must be 16 in. on centers to provide for the accommodation of the lath. All doors and windows should have double studs



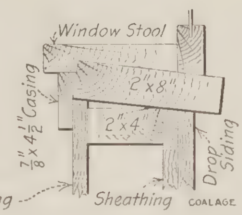
Section at Top

Fig. 4.



Section at Side

Fig. 5.



Section at Bottom

Fig. 6.

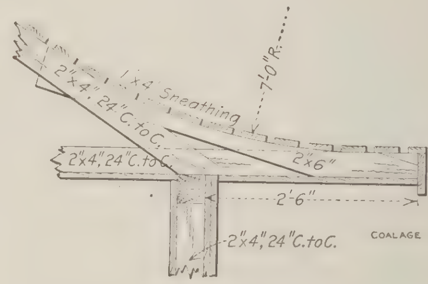


Fig. 7. Details of Shelter

on the sides, and double bridging of the same section as the studs across the top, as shown in Fig. 3.

A good average hight for the rooms is 9 ft., and to avoid waste in cutting, the studs should be ordered in 18-ft. lengths. Partitions are made the same as the walls with the exception that the sheathing is omitted, and at the intersection of the partitions in the four- and five-room houses a support for the chimney should be built, as shown in Fig. 9. On top of the studs is the wall plate, which consists of two pieces of the same section as the studs, the double plate being necessary for the purpose of splicing in order to have it practically continuous throughout.

Rafters and Ceiling Joist

The rafters and ceiling joist for the average house may be of 2x4-in., placed 24 in. on centers, except when it is necessary to provide for plastering they must be on 16-in. centers, as before mentioned. For a shingle roof the rafters should have a one-third pitch and be braced with struts, as shown in the elevation, Fig. 2, which is a cross-section of the four- and five-room houses shown in my first article on this subject. When heavy snow loads are liable to occur, the rafters on the lean-to addition should be 2x6 in., as they are often heavily loaded because of the light pitch.

On the main roof the rafters may butt at the top on a ridge board or against each other, the latter being simpler and probably as good. At the toe the rafters should be notched sufficient to get a bearing the full width of the wall plate and the remainder extended out for the cornice. When the ceiling joist are also the floor joist for the second floor, and the interior finish is to be of plaster, as shown in Fig. 8, they must be proportioned to withstand a certain maximum deflection in order to provide against cracking the plaster. Under these conditions the joist should be designed according to the tables given in one of the standard works on the subject.

Cornice—While anything elaborate for the cornice is not to be expected on work of this character, this detail should not necessarily be entirely neglected. The detail of the cornice shown in Fig. 10, which is the same as used on the three- and five-room houses shown in last week's issue, is simple, economical and very appropriate for this class of work. The projection of the rafter, cut as before described, is boxed in with a 1x4-in. facia and a 1x12-in. plancher, as shown, and an appropriate frieze and bed mold added.

A somewhat more elaborate cornice is shown in Fig. 8, which, with the exception of the gutter, is the same as used on the superintendent's house, shown in my first article. The details of construction are clearly shown, and while this would not be appropriate for the average miner's house, it is a typical example of that used on houses of a better grade. Many different designs of cornice are possible, but the two here shown are good types for use under the conditions specified.

Siding—The siding may consist of anything from common boards laid vertically with joints covered by some form of 2-in. or 3-in. battens, to a double covering, consisting of sheathing and one of the standard sidings. The former is used only on the very cheapest construction, while the latter is commonly applied to all well-built miners' houses.

The sheathing should in all cases be laid diagonally on the sides and nailed at

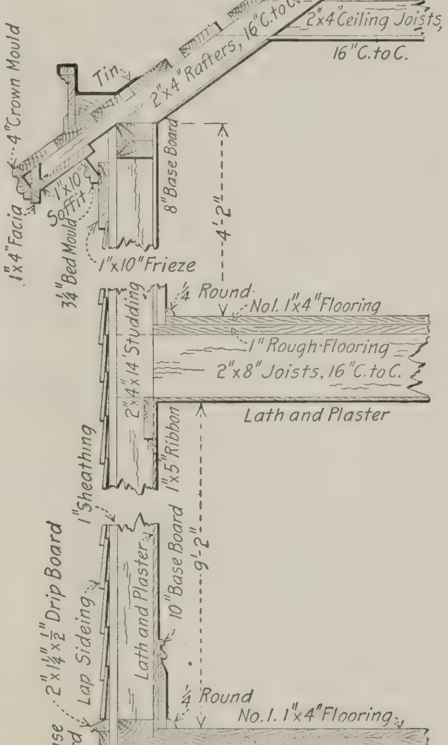

Fig. 8. Construction Details

each stud with two 10-d nails, since it forms an important, if not the only brace for the structure as a whole. In figuring the quantities necessary when laid horizontal do not deduct for the openings, and when laid diagonally allow from ⅛ extra for 10-in. widths to ¼ for 6-in. Considerable waste occurs which makes these allowances necessary. On the good grade of houses of this class one or two layers of a moderate-priced building paper should be laid on the sheathing to eliminate drafts from working through the cracks and joints.

The finished siding is furnished in a number of different shapes and by using a miscellaneous assortment of the design's available a certain individuality is given the different houses.

The sidings may be roughly divided into two classes, the lap siding and the drop siding. Lap or bevel siding is furnished in commercial lengths of about 16 ft., with widths of from 4 to 6 in. and usually ⅜ in. thick on one edge and ⅝ in. on the other. This siding is the most expensive and requires more labor to lay, but is more durable, less liable to check or crack, is usually better seasoned, and dries quicker because of its thinness. It should be nailed only at the studs and with 2½-in. cut nails, and since it can be given any lap required it is the most desirable for the better class houses. It is essential that it be gaged carefully in laying to insure its running even at the doors and window frames.

The different forms of drop siding have a uniform thickness of 1 in. except where chamfered and rabbeted on the top and bottom edges respectively, to fit the adjoining lengths. They run in widths of from 4 in. to 8 in. and the trade names of some of the more popular designs are Drop siding, Channel and Novelty Rustic and Single and Double V-Rustic. Some of the cheaper grades are made in double widths, and have an imitation joint cut through the center.

In figuring the amount of siding necessary, add 20 per cent. to the actual superficial area for drop siding, 50 per cent. for lap siding laid 4 in. to the weather and 33 per cent. for the same when laid 4½ in. to the weather.

Roofing

Shingle roofs are used almost exclusively for this class of houses because of their economy, permanency and excellent results. Shingles are usually 16 or 18 in. long and of random widths varying from 4 to 7 in.; they are also manufactured in lengths up to 24 and 27 in. and widths of 14 and sometimes 16 in. They are usually put up in bundles of 250, four bundles to the "thousand," which is the trade term for the equivalent of one thousand shingles 4 in. wide.

Shingles may be laid on sheathing or shingle lath, the latter being preferable since it permits a certain amount of ventilation underneath, allowing the material to dry quicker, thus preventing decay. Shingle laths are generally 1¼ in. thick by 2 or 3 in. wide and are placed on from 4- to 8-in. centers, according to what exposure is desired for the shingles. Common shingles are laid with from 4- to 6-in. exposure to the weather and, with the former, 1000 shingles will cover 100 sq.ft. while with the latter the same number will cover about 160 sq.ft. On a one-third pitch (8 in. rise to 12 in. run) the shingles should be laid 4 in. to the weather; on a one-half pitch, 4¼ to 4½ in., while for vertical walls they may be 5 or 6 in. to the weather.

Interior Lining—The interior lining for the average miner's house should be of some form of ceiling. While a plaster finish is given to the better-grade houses, the high first cost and the continual outlay necessary for repairing makes the use of this lining very expensive for the ordinary house.

The ceilings run in various shapes having a thickness of from ⅜ to 1 in. and widths of 4 and 6 in. A good average lining for miners' houses is ⅝x4 in. beaded ceiling or 1x6 in., the latter being probably about as economical as the former since the rules in regards to the actual area to be covered to the actual material required are the same as for the flooring. The excess required for the 1x6-in. would be about one-half that for the ⅝x4-in. and the labor would also be less.

Ceiling is also manufactured finished on both sides, Double Beaded or Double-V as the case may be, for use where very thin partitions would not be objectional This construction is sometimes used for the partitions of miners' houses of the cheaper class but is seldom applied to the better grade houses except in some minor position, such as a closet or pantry.

Doors and Windows

The doors commonly used in good construction of this class are 1⅛ to 1¾ in. thick, from 2 ft. 6 in. by 6 ft. 6 in. to 2 ft. 8 in. by 6 ft. 8 in., of No. 1 or 2 grade with a four- or five-panel design. A good average assortment of doors for the well built house would be:

Front door, of No. 1 grade, five panel, 1¾ in. thick and 2 ft. 8 in. by 6 ft. 8 inches.

Rear door, of No. 2 grade, four panel, 1⅜ in. thick and 2 ft. 8 in. by 6 ft. 8 inches.

Interior doors of No. 2 grade, four panel, 1⅛ or 1⅜ in. thick and 2 ft. 6 in. by 6 ft. 6 inches.

Closet and pantry doors, of No. 2 grade, four panel, 1⅛ in. thick and 2 ft. 4 in. by 6 ft. 4 inches.

These doors are all of standard dimensions, such as will be readily found in stock.

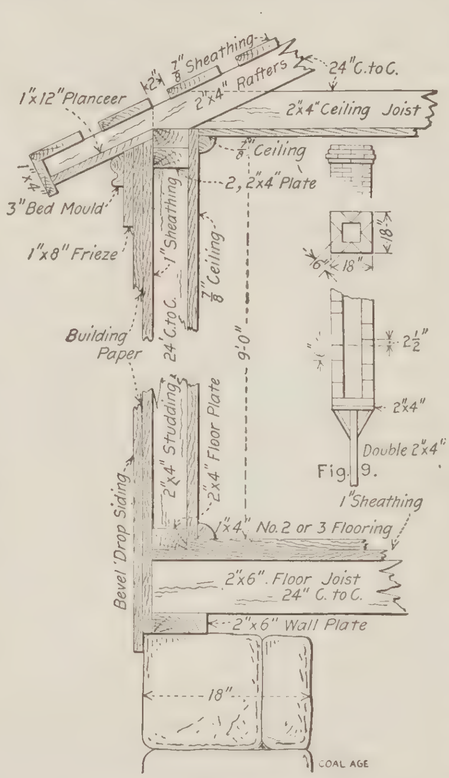
A good average window for these houses is a two-sash, spring-bolt, plain-rail, 1⅛-in. thick, with 8 lights, 12x14 in. This is a fair-sized light and yet not so large as to be very expensive in replacing. If a better class of construction is desired, a balanced window with weight and pullies may be used instead of the spring bolt, in which case the sashes should be check rail instead of plain rail.

The details of a simple window framing for a check-rail spring-bolt window are shown in Figs. 4, 5 and 6. When the windows and doors are of standard dimensions the frames for them can be bought ready made much cheaper than framed on the ground and dimensions and detailed drawings can be obtained from the manufacturers.

Miscellaneous Details

The detail for a shelter, similar to that used on the house shown in Fig. 7 of my previous article, is given in Fig. 7. The one shown in the illustration extends so low as to interfere with the screen door, which difficulty may be overcome by using the method shown in the detail drawing. This detail is one of the bungalow effects, and a certain judicious application of it in different ways will add much to the appearance of the completed town.

A detail of the method of supporting the chimney at the intersection of two partitions, as in the center of a four-room house is shown in Fig. 9. This method is



Figs. 9 and 10. Details

sufficiently strong to carry chimneys 12 to 16 ft. in hight, the maximum which these usually attain.

Some steps are usually necessary at the entrances to the houses, and in laying these out a good rule is to make the rise between 7 and 7¾ in. and the run the difference between 17 or 18 in. and the rise in inches. This rule gives the actual tread, an allowance of from 1¼ to 1¾ inches being made for the nosing, and the actual run consequently being this much less.

If it is intended to use a briquet binder such as hard pitch or asphalt, be sure to see that there is a supply of superheated steam for the mixers or the binder will not liquify enough to spread thin over the coal and will consequently be wasted.

One Man for One Job

Mining experts with experience in India tell how the "one man one job" system is adhered to in that country. The man who fills steam coal will not fill slack. If he comes to a dike he stays off work until a stonecutter has pierced the dike and got to the coal again. The stonecutter remains idle until he gets another dike to cut. The man who drives galleries for the purpose of "winning out" places quickly will not work in ordinary places. A man working at the coal face will not put up a prop; that is the timberman's job. If a stone falls, a coolie must be brought along to clear it away. A special man looks after the pump and he will neither repair it nor clean the suction pipe if it gets choked up. Robert F. Campbell tells how a fireman will fire a double-flued boiler, but not two separate boilers with single furnaces, even though it took him only one hour to do his day's work. Even at that he will only throw in the coal and draw out the ashes. The coal must be placed at his feet and the ashes taken away by a coolie. A winding engineman will not clean his engine, which is only fit work for a coolie. Every squad of men in a colliery is under a head man, who does no work, but must be paid a little for allowing his men to work. It would indeed appear that for the Indian miner the ordinary trades union would be an unecessary luxury; he is quite able to protect his own labor.

Mining Wyoming Lignite

In the vicinity of Hudson and Lander, Wyoming, is a coalfield which is rarely heard of because of the larger coalfields in the United States and Canada, but it is nevertheless an important one, despite its isolation, since it serves a territory which would otherwise have difficulty in securing coal.

The Hudson Coal Company and the Poposia Coal Company are the prominent operators in this field, and are under the management of H. O. Barber, who is president of both companies. The Poposia Coal Company is a new organization, and is just opening up a large mine which will eventually have a capacity of about 1200 tons per day.

The company is operating in a 12-ft. seam of high-grade lignite coal, all of which is consumed by the railroad, towns, and farms of that territory. As their holdings are large, the mine is being made first-class in every particular, and designed for operating through a considerable period of years. The mechanical equipment, consisting of shaking screens, supports and a special device for raising the coal to the tipple, is being installed by the Ottumwa Box Car Loader Company, of Ottumwa, Iowa.

CIRCULATION STATEMENT

Of this issue of COAL AGE, *we will print 6000 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.*

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

COAL AGE

The Adrian Mine Explosion

As was foreshadowed in last week's article by Mr. Hall, dealing with the explosion at the Adrian mine, the coroner's jury did not find it easy to come to a conclusion as to the cause of the accident. Twenty witnesses were examined, many of them being men who were at work in the mine on the morning of the disaster. Some of them had worked in Adrian for years and testified that there was no gas in the mines. The inspectors made their examination, but had not completed their report in time for submission to the coroner's jury.

A caving of one of the headings is supposed to have resulted in the fall of a trolley wire and it was thought that the short-circuit thus caused, ignited the dust naturally upraised in great volume by the violence of this same caving. On the other hand, two miners declared to the jury that there was no electricity in the wires shortly before the explosion; moreover, the falls now visible may be the result and not the cause of the disaster.

An inspection of the mine shows that the wire is down over nearly all the affected district. There are large falls of rock in both back and main headings of the 13th Left. In the main heading, several loaded cars were lifted off the track and turned at varying angles. In the back heading, the cars were empty and the force of the explosion broke several of these to pieces. Some coke was formed at the face of the 13th Left. But the examination does not favor one point of origin rather than another, and deductions are hard to make from the indications.

It seems as if the second Adrian explosion is as mysterious as was the first which occurred in 1896. To all appearances, no one was present when the earlier accident took place, and no one was discovered to be missing after the event. So also in the recent disaster; there were no miners where the explosion initiated.

If the accident was caused by exploding coaldust, the force of its action must have been considerably reduced by the presence of a large amount of sand strewn along the haulways as a result of the continuous sanding of the rails. This sand, covered with impalpable coal-dust, appeared to be in great quantity in the roadways, and conveyed the impression that the entries were dusty enough to provide a rapid detonation, but examination showed that the greater part of the dust was of an inert nature and therefore harmless.

Sand Filling

The Scranton Mine Cave Commission, in its final recommendations, advised that an engineer be appointed to direct continuously whatever plans might be adopted for the sustention of the city. This advice should not be disregarded. Granting that the engineers engaged by the commission made a practical and otherwise able report, fully justifying the reliance placed on them, yet necessarily there were some details to which they failed to give all the attention which would and should receive consideration from an engineer in continuous residence, in the long course of his observation and practice.

The engineers, Messrs. Conner and Griffith, showed among other things that concrete was inadequate and impracticable, and that culm would be unable to support the strata where the depth was excessive. They urged the use of sand—a material which is but little susceptible to compression or deformation and, therefore, one which has a great supporting power. Unfortunately sand often exhibits its other properties. Where it is dry and no binder is present, it will run freely. Should a large crack or crevice occur near a sand pillar, the sand, if loose, would certainly flow into the breach and the surface of the ground would be disturbed, especially if such a failure caused a further breach in the measure or measures above the collapsed sand pillar. Such a further break would be almost sure to occur. The experience in the Rand, where the waste sand of the cyan-

ide tailings is being used for filling, is that sand needs a great deal of constraint, and the miners are said to be afraid of death from smothering, as a result of its sudden, unpresaged outflowing.

There is another undesirable feature in loose arenaceous fillings; they are liable to be swept away by flowing waters. The heavy slag sand fillings in the neighborhood of Cleveland, Ohio, have shown this fault clearly. It is apparent, therefore, that some definite information should be sought as to the possibility of using various forms of cementing materials. Light should also be thrown on their relative values and the best methods of depositing them. Experiments should be tried on the cementing effect of the water seeping through the mine roof.

Let it not be thought that this suggestion contemplates a strengthening of the artificial pillars by cementation, an accomplishment which the report ably shows is impossible, but merely a protection of them from sliding when dry, and spreading or eroding, when in the presence of excess of water. The filler and binder should be deposited in such manner that it merely fills the interstices in the sand and does not collect in local patches, causing undue shrinkage before the weight causes it to take its appropriate interstitial location.

It is probable that eventually, the filler would be found to deform and squeeze into the spaces between the sand particles, but this change in location would not take place till the surface had been severely affected by subsidence. Interesting indeed would be experiments on the nonferruginous sands of the buried Wyoming valley, unmixed or mixed with shales of highly ferruginous type, such as the Mauch Chunk shale or with the slightly iron-impregnated shales of the coal measures, the character of the iron oxide, of course, being as important as its quantitative presence.

At the Myslowitz colliery, in Silesia, ferruginous sand, clay, rock, slag and other débris are used. They are mixed together with bricks, slate and earthy coal. To this is added hot furnace slag—run by launders to the mixing machinery. To quote William H. Storms: "It later becomes a solid mass which can only be broken by a hammer; this is quite in contrast with a sand filling that will run through a knothole at every opportunity."

The only work regarding the cementation of natural bodies of which we have any record is that of Logan W. Page, of the Federal Bureau of Roads. But his experiments were conducted with materials which were not under any pressure and these were not tested under similar conditions to those we are considering. The Federal Bureau of Mines might well make cementation a subject of its valuable research work. It is time that the United States contributed some thought and some examples in the development of a method, which was here originated, but which has received all its later perfecting and development in Germany, South Africa and Australia.

First Aid Inevitable

There have been severe strictures passed by busy critics on the dangers of incompetence in the rendering of first aid. Such critics would have us believe that aid by the layman may be more harmful than helpful.

First aid is not new. It did not originate in mining with Dr. M. J. Shields. It has not been increased in volume by the American Red Cross, but is as old as man. The only change arises from the fact that through the inestimable work of Major Lynch, Doctor Shields and the Red Cross, aided by a numberless body of corporation doctors, first-aid work has been organized, developed and improved, so that instead of being a positive detriment to the subject it is sure to be a help.

Under the old *régime*, it was customary to use for a styptic a wad of tobacco which could not fail to be infected by all the impurities contained in the mouth of the person by whom it was prepared. The hot breath of a friend mollified the smart but infected the tissues of a wound. It was usual to tear off clothing adhering to a cut. Foul coverings were put on burns and abrasions with resulting adherence and infection. Whisky was given in excess to the injured, with distressing effect. Men were gathered up without bandaging; thus simple fractures became compound.

First aid has been with us for generations, and it is here to stay, whether the corporations assist or resist, whether the Red Cross direct or desist in the good work. The only question is whether it will be effective or dangerous, whether it will injure and kill or help and save life. This is a work to which enthusiastic and self-sacrificing men have devoted their lives, with the most excellent results.

But healthy criticism by the friends of first-aid work is needed. Those who most deplore the first aid of the previous centuries will be the first to condemn the continuance of its thoughtlessness in the new first-aid men, who, with all the instruction so liberally meted out to them, occasionally drop back to the untutored practices of a past age.

The Mine Foremen

At a recent meeting of the New York section of the American Institute of Mining Engineers, during which mine safety was the principal topic of discussion, the impossibility of properly directing the non-Englsh speaking foreign element employed in the mines today was discussed, together with the dangers accruing therefrom. During the discussion it was suggested that the mine foreman, being in the minority, should be required to learn the different languages of the majority.

Should such a rule become effective we wish to extend our sympathy to the foremen. As an example of the inconsistency of such a plan we may take the engineers, men who have been subjected to a rigid mental training over a period of a number of years, part of which training was in foreign languages, and how many of these men today can use them? While we appreciate the fact that the mine foremen are undoubtedly the pick of the employees and naturally have superior attainments, on the other hand their mental training has not been such as would make the acquirement of, say, even three or four languages an easy matter.

The excellent illustration on the front cover of this issue shows shaft No. 2 of the Buffalo & Susquehanna Coal and Coke Company, located near Du Bois, Penn., between that town and Sykesville. This plant was built about 1903 and its workings extend to Du Bois No. 1, a shaft mine formerly opened and operated by the Berwind-White Coal Mining Company, but now owned by the same corporation as shaft No. 2.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

After Dec. 15, 1911, all underground mine buildings in the State of Pennsylvania must be of fireproof construction. A fine of $500 for each violation is the penalty imposed for disregarding this law.

The Hillside Coal Company of Avoca, Penn., is fighting a mine fire. An opencut is being put down to the bottom of the first vein, a distance of 50 ft. or more, in order, if possible, to head off the fire. The cost of the undertaking is placed at $25,000.

When installing an electric-haulage plant for a colliery of an output of 1000 to 3000 tons per day, it is desirable, when transmitting the power over long distances to install alternating-current machines; a high potential then can be obtained and maintained, with only a slight loss.

An English authority on coal mining says: "The desirability of quickly reversible ventilation in case of need after an accident cannot be overestimated. When planning a ventilation system bear this in mind, as it may save much loss of life and time in case of fires or explosions."

As an important factor in the solution of the smoke nuisance, use a fire box large enough to allow the flames to burn out before they strike a cool surface, when burning a coal rich with volatile gases. If the volatile matter passes easily from the coal at a low temperature increase the size of the fire box or decrease the rate of firing.

When a mine car is built, the two horses on which it is constructed should be set perfectly level, otherwise the car will be in wind, and run on three wheels and show a perverse tendency to leave the rails. Such a wind eventually works out in practice, but it takes several days during which the ill-constructed car is likely to cause much trouble.

Experience has shown that connected workings, combined with large volume air currents, favor the spread of an explosion because of the large supply of oxygen and dust available. The safety of mines, whose gaseous nature demands a strong current, can be greatly enhanced by splitting the air and keeping the different splits as isolated as possible.

Experiments made in France have shown that, with coal containing from 1 to 6 per cent. of ash the dust from this same coal will contain 40 per cent. or over of ash. This increase is evidently due to the admixture of stone dust from the floors, walls, etc. With an ash percentage of over forty it is difficult for coal dust to give rise to an explosion unless it is fired by a store of explosives or a powerful explosion of firedamp.

A recent consular report from Peru states that American coal, although once popular there, no longer has any market whatever. Peru imports coal chiefly from Australia, although some briquets are brought in from Belgium and England. The limited explorations which have been made up to date would seem to indicate that Peru is undoubtedly rich in both anthracite and bituminous coal, but the amount at present mined is small due largely to a lack of transportation facilities.

A direct-connected turbine pump and motor, at present in use at a Scottish colliery, has a capacity of 24,000 gal. of water per hour against a head of 556 ft. The motor is connected to the pump by a flexible coupling, has a capacity of 110 h.p. at 500 volts, direct current, and runs at a speed of 1850 r.p.m. The pump and motor are mounted on a strong cast-iron girder bedplate, so designed that all may be carried through comparatively small roads and otherwise readily handled underground.

The Bolivian Director of Statistics reports that the coal seams in Bolivia are found embedded in a thick stratum of sand stone somewhat resembling the millstone-grit. The coal seams themselves are small, and although of fair calorific values, are associated with many impurities. The soft nature of the stratum in which they are found increases the cost of working since timbering on the Bolivian plateau is almost prohibitive in expense, and all adits have to be lined with stone. Claims have been staked out on the outcrop for some four miles in length, but none are now being worked.

An 8-h.p. "Otto" oil-burning mine locomotive for underground work has the following overall dimensions for a 2-ft. track gage. Length, 3 ft. 11 in. Width, 2 ft. 7½ in. Hight, 4 ft. 7 in. The gearing is arranged to give two speeds, namely, 4 and 8 mi. per hour. At the slower speed, the locomotive is capable of hauling a gross load of about 23 tons, and at the higher speed, a load of about 9 tons on the level. The service weight of the locomotive is about 4 tons. The oil tank is large enough for a double shift of 16 hours. The fuel and water consumption is exceptionally low. For fuel, crude or refined benzol, petrol, etc., may be used.

The British pit pony, as a rule, is a Shetland, Welsh or Moorland pony, or else a little cart horse which is too small for the surface, but can be used in mines not suited to large horses. With these ponies—the Moor and the Welsh—you practically never see a case of glanders, and F. L. Somerset informed the Mines Commission that the spread of glanders depends largely on the system of watering. If the pony is watered from a bucket and the hostler has instructions not to use a bucket to a horse that is running at the nose from any cause whatever, or to keep that horse with his own bucket, there is not much likelihood of the disease spreading.

Early in the 18th century the mine light *par excellence* was a tallow dip set in a lump of wet clay. When gas tests were to be made the experienced miner surrounded the wick of this brilliant light with more clay. The "fireman" of those days, prototype of the modern fireboss, must have been a man of much nerve and little caution, as his duty was to rid the mine of gas by firing it. Clad in damp leather or sackcloth, duty compelled him to lie prone on the floor and light the gas suspended in the air above him. If he survived the explosion he returned to the surface and reported the mine safe. Another method of disposing of gas was the use of "eternal lamps," kept burning continuously in gaseous mines to burn the gas as fast as it was generated.

Recent consular reports show that during the year 1910, the output of coal in the United Kingdom was 264,417,588 long tons, an increase of 658,216 long tons over 1909. This came from 3253 mines, where 1,049,407 persons were employed. It is interesting to note that of this number 6221 were women, and 72,094 were under 16 years of age. The total number of deaths from accidents during 1910 is the highest ever recorded, being 1775, or 169 deaths for every 100,000 people employed. The injured in accidents numbered 159,042, which amounts to 151 out of every 1000 people employed or over 15 per cent. The annual output of coal per worker has also been estimated as follows for various countries: United States, 500 to 600 tons; Great Britain, 250 to 290 tons; Germany, 250 tons; France, 200 tons; Belgium, 170 tons; Australia, 490 tons; Canada, 425 tons; Japan, 120 tons.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Opening a Colliery

In your issue of Oct. 28, p. 92, you answer a question, "Opening a Colliery." Allow me to suggest another way to open this colliery under the conditions named. I would sink the main-haulage slope in the Buck-Mountain vein instead of in the Mammoth, for the following reasons: The Buck-Mountain is an underlying vein and the upper or overlying veins could then be mined and robbed without injuring the lowest seam. Also the Buck-Mountain vein has the least pitch, and if it is found to be more advantageous the cars could be hoisted to the surface in this vein, with less danger of the coal falling off while hoisting.

A tunnel should be driven from the bottom of the slope in the Buck-Mountain to the Mammoth and this vein, the Mammoth, worked first. As these workings advance the Skidmore vein should be developed and then the Buck-Mountain. This would give a more equalized cost than to work the Mammoth vein alone. The pumping station should be located in the Buck-Mountain vein, as no coal would then have to be reserved to protect it. I would locate the fan on the Buck-Mountain vein and drive a main air-tunnel from the Buck-Mountain vein to the Mammoth and take splits off each of those veins. I would use a blowing fan and drive openings in each vein to the surface for return air courses. This arrangement would be more economical, as it would not be necessary to maintain long return airways.

There are numerous reasons in my opinion why this plan is preferable, but I would be pleased to have some other subscribers give their views on the question, or I shall be pleased to have you criticize my plan.

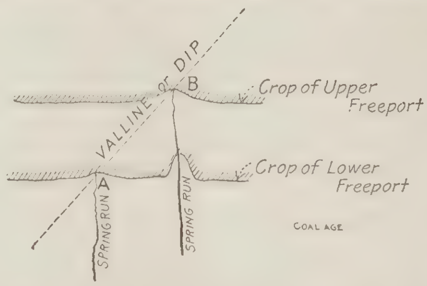
A SUBSCRIBER

Mount Carmel, Penn., Nov. 6, 1911

[We are glad to receive these valuable comments from our correspondent. There may be some difference of opinion in regard to the best method to be adopted in opening a colliery on these seams; but our correspondent's points are well taken. They are particularly applicable in case the parting between the seams is of insufficient strength to maintain a safe and economical condition of the main-haulage slope. In any case, mining should commence and advance more rapidly in the upper seams, the workings in the underlying seams following some yards behind those above. It is also necessary to provide ample protection for all slopes and air courses by leaving sufficient slope pillars in each seam. These slopes and pillars must lie vertically under each other in the several seams.—EDITOR.]

Surface Evidence of a Dip

On the development of a drift opening in central Pennsylvania, in the lower Freeport bed, I noted on the surface that two spring runs descended the hill, crossing its contours at right angles.



TWO RUNS ISSUE WHERE CROPS AND DIP CROSS

One came obviously from the crop of the lower Freeport at *A*, another from the crop of the upper at *B*. The natural assumption was, granting that both measures were similarly folded, that a dip or valline extended in the lower Freeport from *A* to *B*, and for some distance beyond. This dip was found when the drift was opened. The presumption that a dip ran from *A* to *B* was very clear, owing to the short distance between the runs, but with caution the method might be extended with advantage to greater distances, especially where the roof of the lower measure is heavily eroded and the upper measure does not crop near it.

Pittsburg, Penn. H. A. B.

Records for Mine Output

What is probably a Yorkshire record in coal mining, if not a world's record, has been achieved at the Hickleton Main Colliery. Recently the tonnage raised during six days reached a total of 26,986 tons, from a seam which is known as the Barnsley bed. Another record for the week ending Oct. 24 is 25,572 tons from the Crown Farm Pit of the Bolsover Colliery Company. This amount was mined in the time of five days and a half, each of 7 hours and 5 min. duration, only one shift per day being worked. It is said that this latter mine holds the world's record for a day's output, which is 4678 tons of coal.

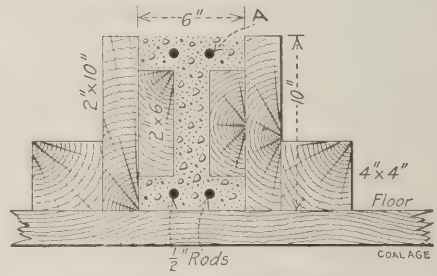
Wigan, Eng. T. J. HEILMAN.

A Homemade Concrete Timber

On an unusually broad parting, or in an exceptionally bad piece of ground, occasions frequently arise where a timber of more than ordinary strength becomes necessary. To meet such an emergency the foreman makes a special order for large-dimension stuff, uses a built-up girder (made of a number of boards nailed together) or falls back on that old standby, the T-rail, with its notoriously uneconomical section.

While no data in regards to costs are available, it is believed that the method here described will not exceed these rather expensive subterfuges in cost, and there can be no question as to its superiority.

The method of construction is clearly shown in the accompanying figure, which is a cross-section through the beam and form. The beam here described is 10 in. deep, 6 in. wide and has a 2-in. web; all dimensions can be easily changed to suit conditions, the ones here shown no doubt being smaller than would be used in practice. As will be noted in the drawing, the form is simply two 2x10 in. boards, with a 2x6 nailed on their respective inside faces. The 2x10's are spiked to the floor on edge, at the required distance apart, and for the sake of additional rigidity, backed with blocks, should this prove necessary.



SECTION CONCRETE I-BEAM

By the use of reinforcement the strength of the beam can be appreciably increased. Thus in the section shown, two ½-in. rods are used, which at the ends of the beam should be near the top of the section as shown at *A*, and gradually lower, until at the middle, they are near the bottom.

The concrete should be a good rich mixture of about 1:2:4 and not to exceed 1:3:5, and made soft to insure its running well. The large aggregate should be sized to pass a 1-in. ring and for beams smaller than this it may prove desirable to decrease this even more.

The size and shape of the beam can, of course, be varied to suit the requirements of the case, but it should be remembered that the strength varies (approximately) directly as the square of the depth. Thus the comparative strength of an 8-in. and a 10-in. beam would be 64:100, or the 8-in. only about three-fifths as strong as the 10-inch.

Better results will be obtained by rounding the corners slightly and filling in angles with small shapes. A more nearly true I-beam is thus obtained, and sharp corners, which are easily broken, thus eliminated.

Boiler Fuel Larry for a Mine Boiler Plant

Few coal-mine tipples are now built without making special provision for taking slack coal directly from the tipple into the mine boiler plant. The usual method is to install a small scraper conveyer, which runs while the screens are running and receives coal through a small opening in the flat screen. This makes a simple and inexpensive apparatus.

Side Dump Larry for Boiler Fuel, and Electric Motor

However, sometimes the power house is situated so far from the tipple that it is not possible to use a conveyer. At the plant of the Central Coal and Coke Company, at Sweetwater, Wyo., the boiler house is about 400 ft. from the tipple and the lay of the ground is such that a conveyer could not be installed. For many years coal was hauled by team up a 5 or 6 per cent. dirt road. Inasmuch as this plant furnishes power to several mines and is consequently of considerable size, it was necessary to employ a team and a man six days a week to supply sufficient fuel.

Having on hand some old electric-locomotive motors, the superintendent built a side-dump larry car, capable of carrying about eight tons of slack, and coupled it through a draw bar to one of these motors, still mounted on the same wheels and axle formerly used in the locomotive.

This rig, shown in the illustration, has given satisfactory service, and the coal supply is now brought by it to the boilers in an hour each day. The team and driver have been taken from this work, and the tipple boss finds time enough to handle the electric larry in addition to his other duties.

An amusing controversy arose as to why the larry developed a greater drawbar pull when running in one direction than when running in the other. Of course, it is obvious, after consideration, that since the motor is mounted on only one pair of wheels, when it is running in one direction and pushing the larry, the tendency of the downward thrust of the draw-bar is to force the motor wheels against the track, thus giving a greater tractive force, while when running in the other direction, and pulling the larry, this condition does not obtain.

Benedict Shubart.

Fan Doors

The explosion door on a fan should not be too readily opened. There is no use in designing it so that it will open for a pressure measured by a few inches of water gage, less than five or six, for instance. A well built fan will not break, especially if run at a high speed at such a low water gage. A door which opens too easily is apt to be wrenched off its hinges, if exposed to a pressure greater than it is designed to oppose. It is better to use a door than to house the downcast with a wood or weak concrete roof without a door. The resistance of such a roof to pressure is indeterminate; besides, such a covering takes too long to replace by boards. Nevertheless it does seem well to arrange the whole covering of the downcast so that a particularly violent explosion will find nothing really solid to oppose its escape in all directions except the fan itself. There has been a disposition to design fan doors and fan-release housings with certain types of explosion in view. It is true that in some places explosions are usually made more violent by reason of the presence of coal dust. It is quite possible that with the care which is now being taken to prevent unsafe coal-dust accumulations, explosions may be, in those localities, less violent in the future, and it may be well to consider the question as to whether it would not be better to provide fan doors rather than such housings as would only open as a result of a more violent explosion.

Byproducts of Coke

It would be impossible to estimate even approximately the waste incident to mining and using coal in its various forms. Every year, however, we are making some progress toward more economy and some dav we will perhaps be realizing greater profit from what is now going to waste than we have obtained in the past from the coal product itself.

Different phases of the industry will be worked upon and developed on a more scientific basis. One of these that has already received attention is the saving of byproducts in coke manufacture.

It is pointed out that hundreds of millions of dollars worth of what may in the future prove valuable byproducts have been wasted in the past by American people and that in this respect the United States is far behind Germany and other foreign countries in adopting the economies resulting from the coking of coal in byproduct ovens.

The first ovens of the byproduct type in the United States were built in 1893 at Syracuse, N. Y. In 1910 there were 4078 byproduct coke ovens, and all of them were in active operation. The greater part of these have been developed, during the past few years. In fact, the greatest activity seems to have been during 1909 and 1910.

Value and Amount of Byproducts

The production of coke in byproduct ovens during 1910 amounted to 7,138,734 tons, which was about 12.17 per cent. of the total production.

The total value of the byproducts obtained from the manufacture of coke in retort ovens in 1910 was $8,479,555, or a little more than one-third of the value of coke produced. This is the thing the industry needs to keep its eye on, the value of the byproduct and the possibility of making it nearly, if not equal to the original product.

It may develop in the course of a few years that we will have in the byproducts of the coal industry a somewhat parallel case with that of the cotton seed, the byproduct of the cotton fields in the South. There was a time when cotton seed was a burden to both the planter and the ginner and was an expensive product to dispose of. Today it is the basis of a large industry and really gets more attention than the cotton product itself.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Fan Ventilation

Ques.—If a mine fan 12 ft. in diameter has an equivalent orifice of 30 sq.ft., and the orifice of the mine is 19 sq.ft.; what is the manometrical efficiency of the fan? What quantity of air will this fan deliver under the conditions given?

H. M. M.

Puritan, Penn.

Ans.—By manometrical efficiency is meant the percentage of useful effect (pressure) produced by the action of the fan; in other words, the ratio of the mine pressure in the fan-drift, to the total theoretical pressure developed in the fan. When the orifices of the mine and the fan are both given, as in this case, mine orifice = 19 sq.ft., and fan orifice = 30 sq.ft., the manometrical efficiency K is best calculated as follows:

$$K = \frac{30^2}{30^2 + 19^2} \times 100 = 71.37\%.$$

Also, from the same data, knowing the diameter (12 ft.) and the speed of the fan (90 r.p.m.), the quantity of air the fan will deliver is found thus,

$$Q = 2.916 \frac{30 \times 19}{\sqrt{30^2 + 19^2}} \times 12 \times 90;$$

$$Q = 50{,}550 \textit{ cu.ft. per min.}$$

The mine gage, in this case, is

$$i = \left(0.00038 \frac{50{,}550}{19}\right)^2 = 1.022 + \textit{inches.}$$

Storage of Bituminous Coal

Kindly give me references concerning the storage of bituminous coal. I desire to know what conditions of coal and storage may result in spontaneous combustion occurring in the coal, and how this may be avoided; also, how to handle a fire started in a large quantity of stored coal. I shall be glad to see such matters treated in your columns, giving examples of current practice and the difficulties met.

H. D. Easton.

Lexington, Ky.

The subject of the storage of coal, both anthracite and bituminous, has been growing rapidly in importance during the past few years of increasing industrial activities supplemented by labor troubles that have necessitated the maintenance of large supplies of fuel by the government, transportation companies, manufacturers and all consumers of coal.

The storage of anthracite coal is mostly a question of the economical handling of the coal, as with ordinary precaution and care there is little fear of spontaneous combustion taking place, except where the coal contains much sulphur and is stored in damp or poorly ventilated quarters.

Bituminous coal, on the other hand, gives much trouble in storage, as it fires readily from spontaneous combustion; and, not only this, but the coal slacks or breaks up and there is a large loss on this account and owing also to the evaporation of the water contained in the coal.

The best reference, to our knowledge, is to be found in Bulletin No. 46, published by the University of Illinois, December 19, 1910, entitled, "The Spontaneous Combustion Of Coal," and giving the results of the investigations made along this line by the staff of the Engineering Experiment Station of the University. The bulletin recites the experience of the Chicago & Alton Railroad Company in the storage of run-of-mine coal from mines of the Springfield district, Illinois.

The Illinois coal, in common with all the coals of the central valley, contains a high percentage of moisture which averages from 12 to 15 per cent. and a relatively large amount of oxygen combined as part of the organic matter of the coal. The evaporation of this moisture, together with the natural structure and cleavage of these coals, causes them to slack readily when exposed to air. This action constantly exposes fresh surfaces to the action of the air and increases the absorption of oxygen, which leads to oxidation, the generation of heat, and finally spontaneous combustion. The high percentage of volatile matter, which is the chief characteristic of bituminous coal, makes it susceptible to spontaneous ignition where anthracite coal, of greater density and containing less volatile matter and a high percentage of fixed carbon would not be affected.

When necessary to store bituminous coal, it should be carefully piled to avoid unnecessary breakage of the coal. The piles should not exceed 6 feet in hight and should be protected from rain and snow by an open shed. The ground should be well drained or there should be a cement floor. The piles may be of any desired length, but the width should not exceed four times the hight of the pile.

The Western Electric Company, in 1902, experimented on the storage of Illinois coal in large quantities under water, at their Polk-Street plant. The results of this trial were so satisfactory that the same company, later, built a large storage pit of concrete, at their new Hawthorne plant. This pit was in three sections, 15 feet deep, and covering an area of nearly an acre; its capacity was 10,000 tons of coal, which could be all covered with water. The sections were crossed by three tracks supported on concrete arches and a track on each side, making five tracks in all from which coal could be unloaded or loaded. The reloading of the coal from the pit was accomplished by a crane mounted on a truck and provided with a huge grab-bucket.

Coal thus stored under water does not require to undergo any drying process. The loss in calorific power or heat value, after being stored twelve months under water, has been found, in certain cases, to be less than 3 per cent.; while the same loss in the case of such coal stored in the open air would range from 10 to 15 and at times reach 20 per cent. A description of the Coal-Storage Under Water, at Hawthorne, Illinois, is found in the Engineering and Mining Journal, March 23, 1907, page 576.

The Oxidation of Coal

Does coal absorb oxygen from the air, at all temperatures, and what is the effect on the coal? In other words, does oxidation always take place in the coal, or is the oxygen simply absorbed and held in the pores of the coal in the same manner as the coal absorbs and holds moisture?

Chemical Engineer

This question has been the subject of recent investigation by the Engineering Experiment Station of the University of Illinois, at Urbana, and some interesting and important conclusions may be found in Bulletin No. 46 of the University of Illinois, page 50.

In answer to the above questions, it may be stated, on this authority, that there appear to be two classes of oxidation that may take place in bituminous coals of the Illinois type, which contain a comparatively high percentage of moisture, generally above 10 per cent.; and are likewise rich in oxygen combined as part of the organic matter of the coal. The initial oxidation, which is not destructive to the coal and produces no carbon dioxide, but rather a change in certain unsaturated compounds of the coal, takes place continuously at temperatures below, say 300 deg. F. At about this point destructive oxidation begins with the production of carbon dioxide.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Interesting Questions

Splitting the Air Current

Ques.—What method of ventilation lessens the danger of an explosion and, at the same time, reduces friction?

Ans.—Splitting the air current in a mine provides purer air at the face of each district or section of the mine. The gases generated in each district are carried at once into the main-return airway by which they are conducted out of the mine. In this method of ventilation, the chances of ignition of gas are reduced to a minimum, as far as the circulation is concerned. Moreover, should gas be ignited, causing a slight explosion, the trouble will usually be confined to the single district in which it occurred. When the main air current in a mine is divided into two or more separate splits or currents the velocity of the air sweeping the working face is much reduced. This not only reduces the friction of the air current, but exposes the workmen often to less discomfort, arising from too strong a wind, and reduces the danger of the flame of the lamps being blown through the gauze.

Relative Diameter and Length of Post Timber

Ques.—Is there any rule that will apply, in general, to post timber in mines, by which the proper diameter of a post may be determined for any given length?

Ans.—The practical question relating to size of posts, in mine timbering, is to determine the minimum diameter, or diameter of small end of a post, such that the post will have equal tendency to crush or bend. It is evident that a long, slim post may bend before the pressure exerted is sufficient to crush the fibers. On the other hand, a short, thick post will probably crush under a weight that is insufficient to cause bending. It can be shown that, for practically all kinds of mine timber, the tendencies to crushing and bending are about equal when the ratio of the diameter of the small end of the post to its length is 1:12. This gives the following practical

Rule: To secure the greatest efficiency and economy, in post timbering, make the smallest diameter of the post, in inches, equal to its length, in feet. Thus, the least diameter of a 6-foot post should be about 6 inches; that of an 8-foot post, 8 inches, etc.

This rule assumes a good and uniform quality of timber, free from knots that would seriously impair the strength of the timber. The ends of the post are also assumed to be squared. Due allowance should be made where the timber does not fulfill these conditions.

Glen Jean, W. Va., Examination

Proper Use of Explosives

Ques. J—(a) What does the law require with regard to the use of explosives in mines? (b) What dangers are likely to arise from the use of explosives in blasting coal or rock in mines, and what precautions should be used to minimize those dangers?

Ans.—(a) The precautions to be incorporated in the mine rules and to be rigidly enforced are:

(1). Take no more powder into the mine than is required for the work of one shift, and what is taken in must be in 5-lb. canisters.

(2). Use clay for tamping, or stemming.

(3). The powder, in any hole, should not occupy more than one-third of the length of the hole.

(4). All coal should be undermined before blasting.

(5). When making a cartridge the miner should put his lamp at a distance of at least 5 ft. from the powder.

(6). In tamping a hole, a copper-tipped tamping bar and a copper needle should be used.

(7). No more than one blast should be fired at one time, and the miner must give warning to the other workmen when he is ready to shoot.

(8). The miner must wait until the smoke from a blast has cleared out of his place before returning to work therein.

(9). Blasting is strictly prohibited in a place where gas may be detected by an approved safety lamp.

(10). All dry and dusty places must be thoroughly watered for a distance of 60 ft. from the face before blasting is permitted.

(b) Careless handling of explosives, using slack coal instead of clay for tamping, putting in too large a charge of powder, and shooting from the solid any of these may be the initial cause of an explosion of either local or general character. Then there is the possibility of the premature explosion of the charge, either when the cartridge is being made or when it is being tamped. Accidents sometimes happen to men who walk up to blasts without having been warned, and when more than one shot is fired at a time, the miner is likely to be mistaken as to the number that explode and be injured or killed instantly by a delayed blast. The practice of firing more than one shot at a time is not approved in this State.

Again, a blast at the face of a room may knock out posts and weaken a dangerous top.

Blasting in the presence of explosive gas, or in a place that is dry and dusty, is a dangerous practice.

If too large a charge of powder is used, if the hole is loosely tamped or stemmed with fine slack, or if a blast is fired in an improperly placed hole, there may result an explosion of the fine coal dust suspended in the mine air. In such cases, the flame from the shot extends into the mine atmosphere and heats the suspended particles of coal dust to incandescence. These particles transmit heat to others, which also ignite, and all of them evolve gas that is inflammable.

The following precautions are suggested as supplemental to those mentioned above. The shooting of the center shot first, following it by shots near the rib, is to be preferred. There is plenty of opportunity for a center shot to do its work with a maximum of certainty. When the center coal is broken down, the two side shots (being loose below in the undercutting and loose on one side where the center coal has been shot out) shoot easily. Thus there are no hard shots to make. In some cases vertical shearing, usually by machine, is used as a supplement to undercutting, thus heavy blasting is rendered unnecessary. With the adoption of any of these methods there is less danger of dust ignition from heavy shooting.

The use of a copper needle and a copper-tipped tamping bar is to be strongly urged and is demanded by law. When a needle is of iron it is liable to strike fire as the hole is tamped. It must be remembered that the needle may move in the auger hole if the hole is not drilled perfectly true, and its point may be in contact with an "iron" ball or nodule. On being suddenly jerked by the action of the tamping bar, the needle may "strike fire." Similarly, as the tamping bar moves forward it may strike an offset in the hole and sparks may be generated, which will ignite the powder prematurely.

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

Liquor Problem in Mining Communities

By C. L. Fay

The Donahoe Coke Company has taken up a comprehensive scheme of welfare work at its mines in Crabtree, Westmoreland county, Penn., included in which is a method for reducing the excessive consumption of liquor. To show, however, that the company's improvements are not merely attempts to control the indulgences of their employees I quote C. Rae King, the superintendent of the mines and the originator of the Greenwald Welfare Plan.

C. Rae King on Welfare Work

He says, "When four- to six-roomed cottages can be built for about the same price per room as the standard eight-room, two-decker-double-red-painted houses, there is no excuse for the tenement-like conditions that exist in the average mining town." Mr. King adds, "Get a good class of men and at the time you employ them make a record of their nationality, whether married or single, their citizenship, religious faith, occupation in the old country and America. Supplement this with a similar census of old employees, including also the number of boarders in each house and you will have a valuable record when it comes to carrying out a definite welfare plan." To quote further, "Provide employees and their families with warm, single houses, encourage them to fix up and clean up, furnish fruit trees and flowers for the yards and control the drink traffic and you will not only assist in developing the character of the young Americans to-be, but you will secure a great increase in the efficiency of your *human machinery* with consequent financial saving to the industry and in part liquidate the obligation you owe to your fellow man and your God."

From these statements of Mr. King it is noticeable that while he is dealing with the liquor problem from the economic standpoint he is, nevertheless, prompted by motives deeper and nobler than those of the mercenary schemer and this will hold true in the cases of all individuals or industries that successfully cope with the problem.

However, the more unique feature of the welfare work of the Donahoe Coke Company is its Greenwald Welfare Committee with its activities in reducing the disposition to indulge in liquor drinking and inebriety. The purposes and aims of this committee as set forth in its code of rules are given below.

Greenwald Welfare Committee—Rules and Regulations

First. The objects of the Greenwald Welfare Committee are to control and minimize the distribution of intoxicating liquors among the workmen of the Donohoe mines; to aid and assist the needy and unfortunate; and to bring about such improvements in the living conditions and general welfare of the community as will appeal to the better class of foreign workmen.

Donahoe Coke Company Mach'ne Shop, Showing Charts That Are Posted Weekly

In order to secure the greatest results in the shortest possible time, the Committee asks that all workmen who desire to make this a clean and law-abiding community in which they can permanently settle and rear their families, coöperate and assist in the removal of the antagonistic and undesirable citizens and workmen.

Second. The officers shall consist of a president, secretary, treasurer and peace officer, and shall be appointed by the superintendent of the Donohoe Coke Company and shall hold office during the pleasure of the superintendent. The offices of secretary and treasurer may be held by one person.

Third. Only one agent of the various breweries and distilleries hereinafter named shall be permitted to solicit orders for beer or whisky upon and about the lands of the Donohoe Coke Company.

Fourth. The said beer and whisky agent shall pay over to the treasurer of the Welfare Committee, for the use of the committee, all moneys and compensation received by him for his services in the soliciting and sale of beer or whisky in excess of the sum of per week, and all such sums so paid as aforesaid shall be devoted to charity work, in accordance with the objects of this committee.

Fifth. Each week a statement will be posted showing in detail the placements of beer and whisky for that week and the amount of money turned into the treasury by the agent; the books of the committee shall at all times be open for the inspection of the public and officers and workmen of the Coke company; and semi-annually a statement will be posted showing the distribution of charity funds.

Sixth. The agent shall explain fully to the workmen the intent and purpose of this movement; he shall comply in every respect with all laws and court rulings as to the sale of beer and whisky.

Seventh. The value of an agent will be determined by the extent to which he is able to reduce the consumption of liquors and beer without causing dissatisfaction among the workmen. He shall show no favors to any particular company for whom he acts as agent; and a reward of $25 is offered for satisfactory proof of the agent's having wilfully favored any brewery or distillery, which $25 shall be paid by the agent.

Eighth. Unless otherwise directed by the secretary of the committee, the agent is to solicit orders only on Tuesday morning of each week and to deliver on Saturday of each week, unless holidays or election days disturb this arrangement, in which case the agent shall call the same to the attention of the secretary in ample time for other plans to be made.

Ninth. The agent is to report and transact all business, relative to orders, with the secretary no later than Wednesday morning of each week.

Tenth. The agent shall gather up empties on Monday of each week, and he shall be responsible for each and every keg or case lost; in the event he reports the party losing the same, the president of the committee will assist in recoveries.

Eleventh. A copy of all orders shall be left by the agent with the secretary.

Twelfth. Until further advised the agent is to solicit as follows:

*Secretary, Coal Mining Institute of America, Wilkes-Barre, Penn.

Note—This is the fifth article discussing the above subject.

Red whisky, $2.25, $2.50, $3, $3.50, $4; bottled in bond, $1.25 per quart. White whisky, $2.50, $3 per gal. Wines, etc., $1.50, $2, $2.50, $3, $4. Rum, gin, brandy, *et al.*, $2.50, $3, $3.50 per gal. Can sell as small a quantity as quarts.

(................) Distillery: Can sell no less than gallon lots. Prices: $2, $2.25, $2.50, $3, $3.50, $4 per gallon.

Thirteen. The said agent shall act as such for the following breweries only: (..............), (..............), (..............).

Fourteenth. Brewers, distillers and other persons interested may send a representative around at any time with the agent while he is taking orders, to ascertain if any influence is being exerted by the agent to cause workmen to buy beer or liquor from any particular company.

Fifteenth. No more than five kegs of beer shall be delivered to any one house in one week unless the occupant of said house obtains an order from the superintendent's office for more; and the agent shall report anyone loaning or giving kegs of beer to another.

Sixteenth. Before transacting any business the agent shall be registered in the clerk of court's office of Westmoreland county, as the agent of the breweries and distilleries by which he is employed, stating the particular territory in which he works, as required by the rule of court.

Seventeenth. Said agent shall act as the *bona fide* agent of the breweries and distilleries employing him; he shall not buy the liquors from the breweries or distilleries and then sell to the customers; the goods must be set apart for the purchaser at the brewery or distillery; the agent shall invariably take the order from the customer in writing and at the time of taking the order he shall inquire of the customer what brewing or distilling company said customer desires to purchase from, and the agent shall take the written order accordingly.

Eighteenth. The dealer can sell only at one place, namely, at the place named in his application for license, and orders received by him for the goods must be filled at that place and title must pass from the dealer to the purchaser then and there. The goods, which then belong to the purchaser, can be taken away by the purchaser himself, or can be delivered to him in the county by the dealer in marked wagons, or can be delivered by the dealer to a common carrier to be shipped to the purchaser; but no device by which the delivery is made, which passes title at any other point than the place licensed, will be tolerated.

Liquor Drinking Reduced

The work of the committee is but partially comprehended in the printed rules. The Donahoe company considered it best not to print the details of the welfare plan in their entirety, but by encouragement and thoughtful leadership to endeavor to inspire the mine employees gradually to develop and request coöperation in the securing of the conditions and privileges which the officials of the company had, in thought, already anticipated.

Mr. Donahoe, in paying a tribute to Mr. King, said: "His plan not only comprehends the philosophy of the survival of the fittest, but it also aims to make the unfit *fit*."

This plan has been in operation since December, 1908.

Before the Welfare Committee started its operations the average consumption of beer at Crabtree was as follows:

Before Control of Traffic

Week ending	
Oct. 3, 1908	880 gal. beer
Oct. 10,	688 gal. beer
Oct. 17,	744 gal. beer
Dec. 5,	564 gal. beer
Dec. 12,	412 gal. beer
Dec. 19,	1188 gal. beer

while under the control of the Welfare Committee there was a decrease as indicated by figures taken from a few of the weekly reports:

After Control

Week ending	
Dec. 26, 1908	396 gal. beer
Mar. 6, 1909	368 gal. beer
Mar. 13,	276 gal. beer
Mar. 20,	340 gal. beer
June 12,	460 gal. beer
June 19,	468 gal. beer
June 26,	412 gal. beer
Aug. 19, 1911	380 gal. beer

When this plan was inaugurated at Crabtree, the company had the usual red-painted double houses and "shacks" to rent to employees. The streets were not graded. The yards were filled with mud, rock, tin cans and beer kegs. There were no gardens, fruit trees or flowers. Some of the miners owned half-starved cows, which were not kept and milked under sanitary conditions. Drunkenness, fighting and disorder were as much in evidence as in similar mining towns.

Chart No. 1 shown below, indicates the purchase of beer and whisky made at each house and shanty under the Greenwald Welfare Plan, Chart No. 2, which follows, exhibits the accrued profits, and the disposal which has been made of them. On page 222 is a view of the

blacksmith shop where chart No. 1, signed by the secretary, is exhibited weekly. Thus every detail of the plan can be followed by all who are interested.

CHART NO. 2

GREENWALD, PENN., June 1, 1911

THE FIFTH SEMI-ANNUAL STATEMENT OF THE GREENWALD WELFARE COMMITTEE FROM DEC. 1, 1910, TO JUNE 1, 1911

Donated by brewers' and distillers' agent for charity		$750.99
Fines for trespass, etc., returned by A. C. Books		3.37
Total amount contributed		$754.36
Expenses for the six months from Dec. 1 to June 1:		
Lumber for new ice house	$305.51	
Carpenters putting up ice house	80.81	
Hauling sawdust, ashes, etc., for new ice house	33.44	
Labor putting up ice	61.50	
Refreshments for men putting up ice	6.00	
Total expenses for six months		$406.45
Balance available for charity		$347.91
Amount available for charity as per Dec. 1 statement		1050.25
Total amount for charity purposes		$1398.16
Amount contributed for charity from Dec. 1, 1910, to June 1, 1911:		
Tony Cashmere, hospital service	$ 7.00	
Tony Cashmere, Dr. Bailey for service	11.50	
Mike Watchio, Dr. Eberhart for service	4.00	
John Smith	15.00	
John Marone, lost his life in mine, paid his mother in Italy	100.00	
Amount contributed for charity from Dec. 1 to June 1, 1911		$137.50
Total amount for charity purposes, June 1, 1911		$1260.66

..............Sect. & Treas.

FIFTH SEMI-ANNUAL REPORT OF THE BREWERS' AND DISTILLERS' AGENT

GREENWALD, PENN., June 1, 1911.

1842 $\frac{1}{8}$-bbl. beer, delivered @ $1.00	$1842.00
40 $\frac{1}{4}$-bbl. beer, delivered @ $2.00	80.00
699 cases beer, delivered @ $1.00	699.00
502$\frac{1}{4}$ gal. whisky, delivered	1437.00
Total cash received by brewers' agent from Dec. 1, 1910, to July 1, 1911	$4058.00
Empty packages returned to brewers on which agent's salary is based:	
1745 $\frac{1}{8}$ bbl.	$436.25
36 $\frac{1}{4}$ bbl.	18.00
632 cases	158.00
Distillers pay whisky agent on 20 and 25 per cent. of sales:	
199$\frac{3}{4}$ gal. whisky and wines, $1410.25, 20 per cent	282.05
9$\frac{1}{2}$ gal. whisky and wines, $26.75, 25 per cent	6.69
Total amount retained by agent for 6 months	$ 900.99
Agent's expenses for six months from Dec. 1, 1910, to July 1, 1911:	
Delivering beer and whisky	150.00
Balance donated by agent to Greenwald Welfare Committee	$ 750.99

[The sixth and last article by C. L. Fay, which will pertain to the general social well being of the citizens of Crabtree, will be published in the next issue.—EDITOR.]

Sanitation in Coal Villages

The Alabama Coal Operators' Association has engaged the service of Morris Knowles, an expert sanitary engineer, to make a study of the social and sanitary conditions in the coal regions of Alabama for the purpose of improving the living and laboring conditions of employees. The association includes practically all the coal-mining companies in the district.

Capt. J. V. Allen, secretary of that body, is authority for the statement that the study would cover the water supplied for drinking purposes, sewerage, garbage disposal and the problems relating to education and recreation.

Mr. Knowles will make a systematic inquiry into every mine camp owned by members of the association, and will then make recommendations to the society suggesting what should be done to improve the conditions of the employees. It was announced furthermore that Maurice Roos Scharff, of the Massachusetts Institute of Technology, a sanitary engineer, formerly employed by the New Jersey board of health, would be in the field assisting Mr. Knowles in the accumulation of data required to formulate the report to be made.

The working and living conditions of the workmen of this district have been greatly improved by the methods adopted by the Tennessee Coal, Iron and Railroad Company. However, some of the smaller companies have not possessed sufficient capital to carry on such a work alone. It seems to be the general idea that the course to be pursued in the undertaking will be to apportion the cost to each company, according to whatever possessions it may have. In that way the expense of general reforms will be borne uniformly and they will be carried to completion along the best possible lines with comparatively small cost to each operator.

BETTER MINERS

The work undertaken will bring, it is anticipated, great satisfaction to those workmen in outlying mining towns who are wholly dependent upon the employers for living environments.

It was announced yesterday by Captain Allen that never before in the history of coal operation had an association of mine owners begun such a work with such ideal views and with such a purpose to guide them in the work.

Mr. Knowles, who is to prosecute the inquiry, is an engineer of eminence. He was formerly with the Federal Government and is known here principally through his late connection with the Tennessee company's operations at its lake construction. He has written articles for the Survey, dealing with social conditions in Alabama fields.

First Aid Hints

A primary requisite of any first-aid subject is air. The first impulse of everybody present is to crowd around. Let the experienced come to the front to treat the patient and let all the mere well-wishers stand back and give the patient air and light.

In cases of asphyxiation, be patient in using the stimulus known as artificial breathing. Cases are known where patients who showed no sign of life after an hour of such exercise have yet been brought to life by patient adherence to the prescribed methods of artificial respiration.

A patient who is but slightly affected by gas should be walked around slowly with loosened collar and open shirt. You may give him half a teaspoonful of aromatic spirits of ammonia in a third of a glass of water every 15 min., but not more than four doses. Soda water may be given a person nauseated by gas to lift off his stomach the foul air he has swallowed.

Don't forget the doctor. Don't be so anxious to do the doctor's work that you fail to see that he is sent for. That would be first-aid run to excess. Remember you are only administering preparatory treatment.

In carrying with stretchers break step; take a short pace not exceeding 20 in.; allow no springing from the forepart of the foot. Keep the knees well bent when advancing your foot.

Watch to see that the stretcher is kept level. Don't choose a squad of tall and short men if you can get them all of a size. Unless the patient has a recent fracture of the thigh or rib, take him foot foremost down hill and head foremost up hill.

All three methods of restoring respiration are based on the expansion and compression of the lungs, due to certain artificial actions. Sylvester expands and compresses the lungs by a raising or lowering of the arms. Marshall Hall produces the same effect by laying the patient on his back and rolling him to and fro, so that sometimes he rests on his back, and sometimes on his chest, while Howard keeps his patients steadily in one position, but pushes the flanks of his naked chest together, by an upward motion, releasing the pressure suddenly when the mouths of the kneeling operator and reclining patient come close together. One man can apply Sylvester's method, but at least three are needed to successfully apply that of Marshall Hall.

When a first-aid patient is wounded in the head, see that the canvas of the stretcher does not press on the wound. Use a rolled coat as a pillow and let the uninjured side of the head rest on it. See that the chin is not leaning forward on the breast.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

The following appropriations for the next fiscal year have been requested for the Bureau of Mines. The figures given for the current year show the actual current appropriations.

The total appropriation asked for the coming year is $784,800; the total for the current year is $425,000.

General Expenses, Bureau of Mines

For the general expenses of the Bureau of Mines, including the pay of the director and the necessary assistants, clerks and other employees in the office at Washington, D. C., and in the field, and for every other expense requisite for and incident to the general work of the Bureau of Mines in Washington, D. C., and in the field, to be expended under the direction of the Secretary of the Interior: For the coming year, $74,300; for the current year, $54,000.

Investigating Mine Accidents

For the investigation of the causes of mine explosions, methods of mining, especially in relation to the safety of miners, the appliances best adapted to prevent accidents, the possible improvement of conditions under which mining operations are carried on, the use of explosives and electricity, the prevention of accidents and other inquiries and technological investigations pertinent to the mining industry: For the coming year, $360,000; for the current year, $310,000.

Fuel Investigations

For the analyzing and testing of the coals, lignites, and other mineral-fuel substances belonging to and for the use of the United States: For the coming year, $135,000; for the current year, $100,000.

For Investigations into the Treatment of Ores and Other Mineral Substances

For investigation into the treatment of ores and other mineral substances, with special reference to the prevention of waste in the mining, and utilization of important mineral resources: For the coming year, $100,000.

Investigation of Coals in Alaska

For the investigation of the coals in Alaska with reference to their mining, transportation and utilization, to be immediately available: For the coming year, $50,000.

Inspecting Mines in the Territories

For the salaries of two mine inspectors, authorized by the Act approved March 3, 1891, for the protection of the lives of miners in the Territories, which states that said inspectors are authorized to inspect coal and other mines in the District of Alaska, to which District the provisions of the Act, except so much as requires six months' residence in a territory prior to appointment, are extended and made applicable; and for per diem, subject to such rules and regulations as the Secretary of the Interior may prescribe, in lieu of subsistence at a rate not exceeding $3 per day each, while absent from their homes on duty, except while in Alaska, and then for actual necessary traveling expenses, including sleeping-car fares: For the coming year, $9500; for current year, $9500.

Books and Publications

For technical and scientific books and publications: For the coming year, $2000; for the current year, $2000.

Building

Toward the construction of a fireproof building for the experimental work of the Bureau of Mines, the cost not to exceed $200,000. For the coming year, $50,000.

Lands, Leases, Etc.

For the purchase or lease of the necessary land where and under such conditions as the Secretary of the Interior may direct, for the headquarters of five mine-rescue cars, and for the construction of the necessary railway sidings on the same, it being provided that the Secretary of the Interior is hereby authorized to accept any suitable land or lands that may be donated for said purpose: For the coming year, $4000.

Alabama

Birmingham—The Bryan Coal corporation has purchased about 1000 acres of coal lands in Walker county comprising the holdings of the Red Star and Eldorado coal companies. Frank Nelson Jr., president of this concern announces that steady development and increased activity will follow.

The Woodward Iron Company has been incorporated with a capital stock of $13,000,000, in Dover, Delaware. It is understood that an issue of $25,000,000 of 5 per cent. bonds will be authorized.

The formal completion of the government mine rescue station was announced Nov. 9 when the State mine inspector, and the various coal companies in the Birmingham district, were informed that the station was ready to answer any and all calls that might be made.

The Alabama Coal Operators' Association has employed Morris Knowles, a well known engineer, and Maurice Scharff, of the Massachusetts Institute of Technology, to study the social and sanitary condition of this district and report a plan for improvements.

Colorado

Meeker—The Lion Cañon coal mine, one of the biggest producers in this locality, has been leased to E. S. Babcock, a well known coal operator, who is making arrangements to operate it on a large scale. Lion Cañon coal compares favorably with the bituminous coal found in Routt county.

Denver—The fourteen union coal miners sentenced to jail on July 14 for contempt of court were released on Nov. 15. The reason given is that the plaintiff, The Northern Coal and Coke Company, having been absorbed by the Rocky Mountain Fuel Company, is not now extant, and is therefore no longer interested in the matter. Judge Whitford's order of release, however, in no wise affects the injunction issued against the men in July, restraining them from interfering with the employees of the various companies in the northern coalfield when a strike is in progress, and from molesting their property.

Illinois

Springfield—The sinking of the shafts of the first of the new mines that are to be put down at Kincaid, midway between Pawnee and Taylorville on the line of the Pawnee railroad, is well under way.

This operation belongs to the Peabody Coal Company, which has extensive holdings in this district and plans to develop them along the most modern lines.

The Jones & Adams coal mine of this city, which claims to hold the State record for the greatest amount of coal mined by solid shooting in one day, has broken its own record. Recently, in eight hours, the men employed in the mine brought to the top 3400.35 tons of coal. Previous to this the shaft held a record of 3017 tons for one day.

Marion—The Burlington is building an extension of about three miles in length

from a point six miles northwest of Marion, to the coal mines adjoining this city. It will connect with the two big Peabody mines and the Chicago-Big Muddy mine.

Indiana

Linton—The Vandalia Coal Company has started mines Nos. 2 and 4, with a force of 150 men each. These mines are located near Linton and have been shut down for three months. Mine No. 2 is the old Island City plant and was the first mine opened in the Linton field.

Lincoln—It is reported that one miner was asphyxiated and 15 were overcome by gas, the morning of Nov. 14 when blackdamp in an entry of the Latham coal mine drove 200 miners from their work.

Oakland City—The Ayrshire Coal Company, owned by the Ingle Investment company, of this city, has begun the work of sinking a shaft for its No. 7 mine, a few miles east of here. The new mine will have a modern tipple of steel construction. Electric haulage will be used and the mine lighted by electricity.

Iowa

Albia—Fire, in the morning of Nov. 11, destroyed a portion of the outside property of the No. 15 Buxton mine of the Consolidated Coal Company. The total loss was about $10,000.

Des Moines—New coal lands are to be developed north of this city, it is said, on a tract of 174 acres, which has been purchased from T. M. Walker by the Claremont Development company for $75,000. It is believed that rich coal deposits underlie the land.

Kentucky

Louisville—The Consolidation Coal Company, building the new city of Jenkins, on Elkhorn creek, in Letcher county, has started another model city on its property across the mountain from the head waters of Elkhorn, on Wright's fork of Boone creek, at the terminus of the extension of the Lexington and Eastern railroad, under construction. The new city has been christened McRoberts, and a post office will shortly be established.

Eighty-five per cent. of the twenty-eight-mile coal road, which has been in process of construction during the past six months from Shelby, Ky., to Elkhorn, is now completed, and it is hoped by spring that the entire line will be finished.

The Wilhoit Consolidated Coal Company, Bell county, has filed with the Secretary of State a notice to the effect that the corporation has changed its name to the Wilhoit Coal Company.

The mine of the Majestic Coal Company near Centralia is producing coal in small quantities and as soon as railroad facilities are obtained it is hoped to obtain an output of 500 tons per day.

Barbourville—It is reported that the Black Mountain Coal Company will develop 5000 acres of coal land in Harlan county.

Michigan

Lansing—What is believed to be the largest field of bituminous coal in Michigan has been discovered in a territory comprising 775 acres of land a mile west of Flint. It is said that development of the property by the Genesee Coal Mining Company, which is now operating a mine east of Flint in Burton township, will soon be begun.

Minnesota

Duluth—A total of 810,642 tons of coal, both bituminous and anthracite, was received at the local coal docks during the month of October, according to the records just compiled at the customs offices.

In a recent test made by the Pittsburg Coal Company of its new dock No. 7, the steamer "J. S. Ashley," with 8983 tons of lump coal, was unloaded in 10 hours and 15 min., and the cargo of the "J. E. Upson," 8747 tons of the same grade, was taken out in 10 hours and 55 min., actual working time. This dock has just been completed and is equipped with three bridges of the most modern pattern.

Missouri

St. Louis—It is reported that representatives of the Iowa Central and Minneapolis and St. Louis railroads, have been in the Novinger field inspecting the coal properties there and that they have been negotiating with the owners of the Great Northern Fuel Company and the Manufacturers' Coal and Coke Company with the view of buying their mines.

Ohio

Cleveland—The National Coal Company, of Cleveland, petitioned the Interstate Commerce Commission, Nov. 16, for $30,000 reparation from the Baltimore & Ohio Railroad Company on shipments of coal from Guernsey county, Ohio, during the years 1900 to 1908. It was said that the company went into business in 1900, and owing to the coal-car distribution rules of the railroad suffered great losses, which it now wishes to be made up to it.

Vessels are coming in for at least one or two cargoes of coal at a profitable freight rate before the close of navigation this fall. Some charters were made recently at 50c. a ton, 20c. higher than the rate paid for months.

Bellaire—The Pennsylvania company has required the Rail and River Coal Company to change the position of some of its tipples. They must be set back further from the tracks. Material for the work is on the ground and is being installed as rapidly as possible.

Columbus—With a view to meeting the sentiment among the independent coal operators in Ohio, the railroads which penetrate the coalfields are working on a schedule of freight rates on coal shipments which is expected to satisfy many of the malcontents; but it is not believed the movement is strong enough to influence the coal companies from withdrawing the litigation which is pending in a number of courts. The coal operators are asking for a flat rate of 75c. from the assembling yards at Nelsonville to Toledo, whereas $1 is the present rate.

Pennsylvania

Bituminous

Punxsutawney—At an inquest held by the coroner in the cases of the eight men who were killed by the explosion at the Adrian mine of the Rochester & Pittsburg Coal and Iron Company, it was found that two of the men were killed by the force of the explosion while the other six died later, from carbon-monoxide poisoning. The jury reported that it was unable to determine the cause of the explosion.

Uniontown—It is estimated that at least $100,000 in improvements is being expended by the Rainey company at the Mt. Braddock works, in addition to the amount spent during the past two years in changing the ovens from the beehive to the Mitchell type. The present improvement consists in the erection of a large brick boiler and compressor house, and the instalment of a complete outfit of boilers and air compressors.

Saltsburg—The Penn-Mary Coal Company, of Heilwood, will establish a mine-rescue station, with full equipment. Several crews for first-aid work are being organized.

Du Bois—It is reported that the Buffalo, Rochester & Pittsburg railroad interests are making arrangements for a new opening in this field, about a mile and a half above Jacksonville, on the Rhea farm, where, it is said, a new mining town will be laid out in the near future. Recently this company purchased about 600 acres of the best land in that locality. Other territory in the immediate vicinity has either been purchased or is under option by this company.

Extensive repairs are being made on the company's properties at Ernest and Lucerne, and it is understood that the output of these mines will be increased.

Pittsburg—Col. H. C. Newcomer, of the local United States engineers office has submitted his report on the preliminary examination for the canalization of the Allegheny river, to the chief engineer, Washington, D. C. He recommends the

construction of five additional locks and dams in that river at the present time, which will carry slackwater above the mouth of the Mahoning river.

The Interstate Commerce Commission's hearing on the Pittsburg-Lake coal rate began Nov. 21, at Washington, D. C. It is believed that this hearing is the crucial one in the case and that it will result in a substantial reduction of the 88c. rate. The shippers are making their leading argument a comparison of ton-mile rates, after allowance for terminal expenses, between the Pittsburg district and the competitive districts in Ohio, West Virginia and Kentucky. Even with a large terminal allowance the Pittsburg-to-Lake ton-mile rate is shown to be relatively high.

Anthracite

Scranton—Because of the high price that coal sold for at tidewater during October, the mine workers of the anthracite region will benefit to the extent of an increase of 8 per cent. over the regular rate of wages. Only once before in the history of the award made as a result of the 1902 strike has the sliding scale reached 8 per cent. That was in April, 1906.

One of the most serious caves that has taken place in Scranton for some time occurred on Monday morning, Nov. 20, in Ross avenue. The subsidence engulfed a double frame building and seriously damaged a number of houses in the immediate neighborhood.

The cave is at least 40 ft. wide and 50 ft. deep. The settling began at 5 o'clock in the morning and the house sank into the cave five minutes afterward. The residents had an exceptionally narrow escape. A lamp exploded, setting fire to and completely destroying the building.

The settling was due to the workings of the Von Storch mine of the Delaware & Hudson Coal Company.

The Delaware & Hudson company, according to C. S. Sims, vice-president and general manager, has in the neighborhood of 200,000 tons of coal in storage at Carbondale, Penn., and Schenectady, N. Y. Mr. Sims states that the prospects are that the Delaware & Hudson mines will work uninterruptedly through the winter, not because of the expiration of the contract with the mine workers, but because of the demand for coal.

Wilkes-Barre—A party of men entered the mine of the Pennsylvania Coal Company in the vicinity of Cork Lane, and undertook the task of blowing down a mass of coal and rock without the company's knowledge. The matter is now being investigated. Their object was to protect a certain house which was in danger, should the pillar of coal be removed.

Pennslyvania's production of anthracite coal reached the total of 83,683,994 tons during 1910, according to the annual report of the chief of mines, which has just been issued. This production is the largest in the history of the hard-coal industry, with the exception of 1907, when the tonnage mined aggregated 86,056,412.

The Lehigh Coal and Navigation Company is making experiments with a new type of motor boat, which, if successful, will result in displacing the tow-path mule.

Hazleton—The repairs being made to the company houses at Drifton by the Lehigh Valley Coal Company, have noticeably improved the appearance of the whole town.

Washington

Spokane—The Western Fuel Association, composed of 500 retail dealers in Washington, Oregon, Idaho, Montana, Utah and Wyoming, will discuss various matters of interest to the trade at its convention in Spokane on Nov. 27.

Seattle—Patent to 150 acres of coal land in Whatcom county was issued by the government land office recently, this patent being the first to go from the local branch in a period extending over almost a year. The land is in the Glacier district and cost $20 an acre.

West Virginia

Charleston—It is reported that the explosion in the Bottom Creek Coal Company's mine, at Vivian, McDowell county, on Saturday last was due to gas, which had accumulated in a temporarily abandoned entry of the mine, the gas being ignited by an engineering crew who were exploring the mine. The men used open lamps, and from the information received at the Department of Mines, the workings, although known to have a little gas, had not shown it in any quantities, and a notice that the particular section had been temporarily abandoned had not been posted by the fireboss, as required under the rules.

Of the 18 men killed, it is believed that the deaths of only four, or eight at the most, were due directly to the gas explosion, which was local. It is thought that the others lost their lives under falling slate. To the fact that there was no explosion from coal dust a great many men who were in the mine at the time owe their lives. The mine was well watered, making a dust explosion practically impossible.

This is the first serious explosion of any kind in this region for a long time, and the first in the Norfolk & Western section for several years. The engineers were sent into the mine by the owners of the land and not by the coal company; all were killed outright. Chief of the Department of Mines John Laing and a number of his deputies are now on the scene, and an effort will be made to fix the responsibility for the explosion.

Huntington—Announcement was made recently of a deal closed by Parkersburg people, with Pittsburg and Philadelphia capitalists, involving the transfer of 3400 acres of coal land on Spruce fork of Little Coal river, in Logan county, the purchase price being $250,000. This coal region has recently been opened up by the extension of the Guyan Valley line of the Chesapeake & Ohio Railroad, and the purchasers will begin development in the territory at once.

Virginia

Bristol—The Dominion Coal Company, with a $150,000 capital, operating mines in Lee county, Virginia, under lease from Black Mountain Coal Lands Company, of Bristol, is now in the hands of a receiver.

Norfolk—It is reported that the general offices of the Chesapeake & Ohio Coal and Coke Company will be moved to Norfolk in the near future.

Canada

British Columbia—Three thousand miners, who have been on strike for more than six months at British Columbia and Alberta coal mines, have returned to work. It is understood that the miners have accepted terms which mean an increase for some men but involve a reduction for contract and pillar work, according to Gordon's findings. The check off is to be handled by the secretary of the union, who must have each man sign for it every month at his option. This virtually means open shop. The agreement is for four years expiring April 1, 1915. It is claimed that the mines will be producing as usual about Dec. 1.

Vancouver—As a result of the October visit to Vancouver island of Andre Lazard, of London, England, manager of the English financial institution known as Lazard Frères, that house has invested $3,000,000 in coal properties on the island's east coast. A large part of the investment will be used for exploration work and for installing haulage power, made possible by hydroelectric plants which utilize the natural water force near the Extension and Cumberland coalfields. This undertaking will occupy the greater part of 1911 and 1912.

Personals

W. H. Loomis has resigned as general manager for the G. B. Markle Coal Company, at Jeddo, Pennsylvania.

O. H. Reinholt, formerly of the Mesabi range, the Philippines and California, reported for duty in the Bureau of Mines, July 14.

H. S. Matthews, former vice-president

and general manager of the Alabama Consolidated Coal and Iron Company, has succeeded Joseph H. Hoadley to the presidency of that company.

Frank H. Crockard, vice-president and general manager of the Tennessee Coal, Iron and Railroad Company, recently escorted a party of Steel Corporation officials over the company's property.

Lowther Ferris has resigned as sales agent of the Carnegie Coal Company in Wisconsin and Minnesota, to take charge of the sales department of the Canadian Collieries Company, with mines on Vancouver island.

T. H. Watkins has been elected president of the reorganized Pennsylvania Coal and Coke Corporation. T. H. Watkins, C. D. Simpson, W. A. Lathrop, Samuel Heilner, Stacey C. Richmond and A. J. Hemphill are directors.

James Bonnyman has resigned as general manager of the Birmingham Coal and Iron Company, effective Jan. 1. This company has been absorbed by the Woodward Iron Company. Mr. Bonnyman will open several small mines near Cardiff, in Jefferson county, Alabama.

James Ashworth, of Vancouver, B. C., has been engaged by the Head Syndicate, Ltd., of London, England, to examine and report on its coal-mining property, situated on the south fork of Old Man river, southwestern Alberta, which property is being developed by the syndicate, with Leslie Hill, of Nelson, B. C., as manager.

Frederick P. Cook, former secretary of the Milwaukee Locomotive Manufacturing Company, has been placed in charge of the New York offices of the company, with headquarters at 111 Broadway. Mr. Cook will handle sales in the States of New York and New Jersey, and will also look after the company's foreign business.

Book Reviews

AMERICAN RED CROSS ABRIDGED TEXT BOOK ON FIRST AID. Industrial Edition, by Major Chas. Lynch and First Lieut. M. J. Shields, 49 illustrations, 175 pp., 16-mo. P. Blakiston's Son & Co., 1012 Walnut street, Philadelphia, 1911.

There can be no better indorsement of the contents of this book than is provided in the names of its authors. It is needless to add here the statement on the title page that the work was "prepared for and indorsed by the American Red Cross."

The introductory chapter describes in simple words with the aid of five diagrams the nature and work of the parts of the human body, leaving out all considerations not pertaining to first aid. Then follows a chapter on the material used in preliminary treatment of the injured. This is followed by others on shock, mechanical injuries, injuries from heat, cold, electricity and poisoning. Carrying the injured and the avoidance of accidents are treated in separate chapters and the book winds up with a suggested method of organizing for first aid and finally a good index which makes it possible to locate the treatment for any ailment without delay. The book has already been published in the Italian, Slavish and Polish languages.

JOHNSON'S FIRST AID MANUAL. Suggestions for First Aid to the Injured in Accidents and Emergencies. Edited by Fred B. Kilpmer. Fourth edition revised, 128 pp., octavo. Johnson & Johnson, New Brunswick, N. J., 1909. Price 50c. cloth bound, 25c. in paper.

There are few books as simple and as practical as this little manual. It has the advantage of being self contained. Does the reader want to know how to stop bleeding of the head? There is a practical page full of illustrations which show just how the work is done and then to make the methods plain in the center of that same page is a head with all the arteries showing. These blood passages are in bright red so that they cannot fail to be distinguished. The charts of circulation are in close companionship with the treatments based on them. There is no necessity to search the volume through to correlate the treatment and the facts on which that treatment is based. The book is well illustrated and practical and well arranged for reference.

Publications Received

Report of Topographic and Geologic Survey Commission of Pennsylvania. 1908-1910, giving the results of two years' work in coöperation with the U. S. Geological Survey. Papers on the present status of natural-gas development and a preliminary list of the fauna of the Allegheny and Conemaugh series in western Pennsylvania are embodied in the report.

"The Resources of Tennessee," for October, containing a preliminary report on the coal resources of the Pikeville special quadrangle of Eastern Tennessee. This is a monthly publication of the State Geological Survey.

"Geology and Mineral Resources of Parts of the Alaska Peninsula," by Wallace W. Atwood, Bulletin 467 of the U. S. Geological Survey.

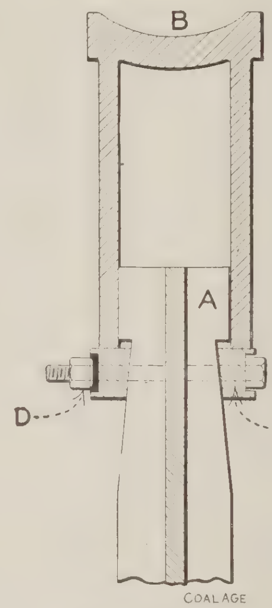
Industrial Item

The General Electric Company reports having sold mining locomotives as follows: One locomotive to Asker Coal Mining Company, for Dorothy, Ky.; one to Ben Franklin Coal Company, for Braeburn, Penn.; one to Inland Steel Company, for Crosby, Minn.; and one gathering locomotive to Davis Colliery Company, for Elkins Colliery Company, Bower, W. Va.

Coal and Coke Patents

UNITED STATES

Prop for mines; August Winz, Rüttenscheid, Germany. No. 1,006,163. As indicated in the drawing, this device consists of an I-shaped support, a head piece and a bolt and nut with two beveled clamps. The support has a head which, projecting up inside the top section, holds it rigidly in a vertical position. Below the head of the I-shaped support the flange faces are slanted and the length of the prop can be altered to a limited extent by adjusting the bolt to hold the clamps at the desired point. Each clamp extends across the two faces of the I-beam on each side and the web of the latter is slotted to permit an up and down adjustment of the bolt.



PROP FOR MINES

Attachment for mining machines; Louis F. Hess, Hawks Nest, W. Va. No. 999,-996.

Coal-mining machine; John Sutch and William M. Clark, Somerset, Colo. No. 998,654.

Briquet press; James John Shedlock, Little Bentley, England. No. 1,000,204.

Calorimeter; Gordon Maynard Evans, New York, N. Y., and John Scouller Beckett, Fanwood, N. J., assignors to Fuel Engineering Company, New York, N. Y. No. 1,000,082.

GREAT BRITAIN

Improvements in coal washing, etc.; W. M. Mackey, Leeds, England. No. 763 of 1911.

Improvements in miners' safety lamps; R. Cremer, Leeds, England. No. 8632 of 1911.

Improvements in and means for quenching the coked product of coke ovens, etc.; A. O. Jones, Whitley Bay, England. No. 28,662 of 1910.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The cold wave, prevailing in all parts of the country, has resulted in a vigorous buying movement, the effects of which have been felt at every producing center. Prices are firmer than at any time this season, and reports of cutting are infrequent.

On the Atlantic coast, gales and generally inclement weather, causing the total loss of one coal freighter, have seriously interfered with coastwise shipments. As a result, water freights are the highest they have been for a number of years and supplies, particularly in some sizes, are short, with orders usually behind.

The Pittsburg mines continue working on about 60 per cent. capacity, although adjacent distributing points report heavy tonnages and demands good. Prices remain at the same level with some cutting, and the coke market shows a slight improvement.

In Ohio and fields to the south supplies are small and the trade brisk. Prices are firm, even advancing in some instances, and consumption heavy. Indications are that more than the usual tonnage is being stored on vessels at eastern Lake ports to be held over; this in anticipation of labor troubles the coming April.

A restricted movement of Eastern coals to the Middle West and an acute car shortage on the Gould and Illinois Central lines have materially strengthened this market. Prices are variously reported as advancing or low but firm. The cold weather has seriously depleted stocks and an unprecedented demand is reported in some districts which railroads and mines are unable to meet.

Mines in the West are working full capacity and a slight fuel shortage in the Northwest appears inevitable as a result of the Crow's Nest strike during the summer. On the Pacific coast cars are becoming scarce with large accumulations on sidings in need of repairs due to the strike on the Harriman lines.

New York

The shortage of marine transportation is being felt here as elsewhere and exists not only in the supply of barges and scows engaged in the Sound business, but is also in the harbor transportation. Many boats engaged in the Sound trade are taking more than twice the usual time for round trips and the slowness of the vessels is interfering with the movement of coal from the New York loading ports, which is causing some accumulations at the piers. Railroad movement, however, does not seem to be as good as it has been and the coal is not accumulating to any serious extent. With the return of favorable weather conditions for marine transportation, the stocks now on hand at the piers will be quickly reduced. Except in one or two instances, there are no consumers along the Sound, reporting shortage on account of delayed transportation. This is probably owing to the fact that most consumers are rather heavily stocked this year.

On account of the slow movement, the market here at New York for the better-grade steam coals, while not strong is fairly firm. For inferior steam coals there is little demand, either spot or contract, and they can only be sold at prices that in most instances do not equal the cost of production. The amount of new business coming into the market is limited and is for the standard grades of steam coal only.

The slack market in the territory tributary to New York is considerably improved from the weak position it has been in this fall. There is a good deal of inquiry for spot shipment but the supply is apparently reduced and as the shipments to the Lakes are discontinued, the supply of this fuel will be further contracted.

There has been no material change in the prices at which tidewater coal has been quoted, for the past two or three weeks.

Boston, Mass.

The heavy storm a week ago and the succession of gales since has made decidedly worse an already complicated situation, and all interests are trying to "find" themselves.

F.o.b. prices on Pocahontas and New River are being firmly held at $2.60, and it is quite likkely, if freights hold up, that there will soon be some new business. Then the operators who have not tied themselves up with long-term delivered-price contracts in the East may reap some reward for their prudence. New England must have coal and the shortage must be made up. Prices on cars at Mystic wharf are said to be up to $3.85, the highest figure for some seasons, and prices at the other points range from 10c. less at Providence to 10c. to 20c. more at Portland and Portsmouth. At retail in Boston an advance to $4.50 per net ton is likely soon to be made.

On the Pennsylvania soft coals there is little change. A large proportion of those loaded at Philadelphia for this market comes in anthracite barges, and the movement of these has been much better than on sail tonnage from the Southern ports. On coals dependent on outside transportation freights are up, and from New York to Long Island Sound points 60c. has been paid this week. Prices for the better grades of Somerset county are still at $1.15@$1.20 at the mines, only slightly higher than the summer figures.

Buffalo, N. Y.

Soft coal is moving decidedly faster than it did last month, though there is nothing to account for the improvement but the season of the year, as it would be unusual if there was no stir as the cold weather comes on. Some factories are starting up and it is the rule to put in an extra stock against unforeseen contingencies. If prices were going up with the increased consumption there would be no complaint, but they do not show any improvement yet.

The improvement in the soft-coal demand has enabled practically all the Allegheny Valley mines to run full time and if they could secure an advance of even 5c. a ton there would be a different tone to the market. As it is, the competition from districts farther away from Buffalo is such that it is impossible to advance prices.

The near future of the soft-coal trade, especially in the Allegheny valley, is not promising and there is much talk of the day when production will be controlled in some way, so that it cannot exceed the demand. Prices remain nominally unchanged at $2.50 for Pittsburg three-quarter, $2.40 for mine run and $2 for slack, with Allegheny Valley 15 to 25c. less. Coke is still dull at $4.25 for Connellsville foundry and $3.50 for stock coke.

Philadelphia

There has been no change in the situation this week as compared with last in the retail trade. The demand continues unabated for all sizes, with stove and chestnut still leading the van, and reported from all sides as behind on orders. The advance in the price of chestnut seems to have added to its popularity, rather than detracted from it, and it is understood that this holds true in almost every section of the country. Pea

coal is used extensively in this locality for furnaces as well as kitchen ranges, its use as a domestic fuel seeming to increase and, as a result, it will not be long before there will be a shortage in this size.

In the wholesale trade, there is still no let up. From all quarters come hasty inquiries for tidewater as well as rail coal, and to all of these requests there is but one reply, that orders will be filled as promptly as possible. No other guarantee can be given. Outside vessels for the movement of coal are reported to be short, and freights are accordingly inflated. To Southern ports freights are anywhere from 10 to 25c. over quotations earlier in the season, with nothing particular offering at that. Prices remain unchanged.

Pittsburg

Bituminous—Some belated shipments are being made in the Lake trade, but the movement is practically over. Manufacturing demand has been only fair, while the past week saw a material increase in demand for domestic, which has been quite good. The early buying was unusually light, but the cold snap of a week ago brought buyers more freely into the market. Mine operations have been somewhat curtailed, the present average being not much above 60 per cent. of capacity in the Pittsburg district. There continues to be much price cutting by interests which have not much contract business on books. Slack has not yet firmed up any, as it usually does at the close of the lake season. We quote as the average market level: Nut, \$1@1.05; mine-run, \$1.05@1.10; 3/4-in., \$1.15@1.20; 1 1/4-in., \$1.25@1.30; slack, 40@50c. per ton at mine, Pittsburg district.

Connellsville Coke—Sales of over 150 cars of prompt furnace coke have been made in the past week, all at \$1.50. Several consumers have been buying regularly in the past few weeks, having insufficient coke on their contracts which, of course, are at a higher price than the prompt market, and no more coke is taken on contract than the buyer is obligated for. As a rule negotiations for next year's contracts have not been taken up, but in a few instances buyers and sellers have gotten close together, and news of two or three contracts being closed may come any day. Foundry coke shows no change. We continue to quote: Prompt furnace, \$1.50@1.55; contract furnace (nominal), \$1.65@1.75; prompt foundry, \$1.80@1.90; contract foundry, \$2@2.25, per ton at ovens.

The *Courier* reports production in the week ended Nov. 11 at 323,363 tons, an increase of 600 tons, and shipments at 3639 cars to Pittsburg, 4873 cars to points west and 1048 cars to points east, a total of 9560 cars, a decrease of 500 cars.

Cleveland, Ohio

A large amount of coal ordered to the lake front, is still being loaded in boats for storage to be held over at this end of the route. Vessel men are getting 20c. a ton for holding cargoes. There will be a large amount of coal on board at this end, as well as at the upper end of the Lakes. This surplus is prompted largely by the miners' scale coming up next April, and the uncertainty of a strike, in which case this coal will insure a supply, for a time at least.

The domestic trade in the past week has been brisk, owing to the cold snap. There is little improvement in the steam trade, and prices range about the same as a week ago, except in slack, which owing to Lake shipments being shut off, are holding stiff and gradually advancing.

Columbus, Ohio

Real winter weather in the shape of a cold wave was the salvation of the coal trade in Ohio during the past week and improvement has been reported from every mining district in the State. One of the best features of the trade is the better demand for domestic grades and activity is shown in every department of the business. Prices on all grades rule firm to the extreme and complaints of price cutting are not as numerous as several weeks ago.

One of the worst features is the approach of a car shortage which is affecting mines on both the Hocking Valley and Toledo & Ohio Central Railways. The cold snap caused some inconvenience upon that score and in some places deliveries were delayed for several days. Other of the coal roads up to date have been able to move shipments promptly, although the indications are good for a general car shortage in Ohio and contiguous States.

The steam business has also shown some improvement in the past few weeks, although the requisitions of the larger manufacturing concerns are not being increased fast. The reports show that stocks in the hands of the large steam users are small and the cold weather is expected to stimulate that trade as well as the domestic business. Contracts which expire at this time are being renewed at the same figures which prevailed during the past year.

Prices prevailing in Ohio fields are: Domestie lump in the Hocking valley, \$1.50; domestic lump in Pomeroy Bend district, \$1.60@1.75; 3/4-in., \$1.35; nut, \$1.15; mine-run in eastern Ohio, 95c.@\$1.05; mine-run in the Hocking valley, \$1.05@1.15; nut, pea and slack, 40@50c.; coarse slack, 35@45 cents.

Cincinnati, Ohio

The car situation is tightening and coal offices are kept on edge for fear orders will be filled in railroad cars objectionable to the purchaser. That should be sufficient evidence that "things are looking up" in the local coal market, which they are. When the operators are tempted to disregard orders and take a chance on sending hopper cars when flat-bottoms are specified in the contract, it is an indication there is no surplus of equipment which means heavy production.

This friction because of equipment ordered and that actually used has arrived about 30 days late, and corresponds well with the lateness of the season. The cold weather, which has continued for almost two weeks now, has relieved the market of a large surplus. In addition, the orders for steam fuels are increasing, and altogether the coal offices are enjoying a good business. The lower grades of fine coals are still to be had at low prices, but this does not apply to the higher grades, which are in fairly good demand and are being held for the price which has ruled in this market for some time—50 to 75c.

Charleston, W. Va.

Unless there is an increase in demand for domestic coal there is likely to be a slump in output in the Kanawha and New River territories by the end of the year. The last shipments for the lakes were scheduled for Wednesday, and unless changed, it will be necessary to cut down in output, providing the increase for domestic, due to the cold weather, does not relieve the situation. Weather conditions are rather favorable, but whether they will be sufficient to make up for the loss in the lake trade is doubtful in the opinion of the coal men.

There has been no general complaint about cars, but with the increase in shipments for domestic trade East some trouble, as usual, is anticipated a little later.

The same usual complex conditions prevail in the Kanawha and New River territories. In some instances conditions are looked upon as being good, while in others there is the usual hard-luck cry with business anything but encouraging. The time cannot be recalled when the conditions were the same from one end of these contiguous territories to the other.

Gas coal from the Kanawha territory is quoted at the mines, mine-run, 85@90c., and lump or screen at \$1.25@1.40. In the New River district nearly all coal is run-of-mine, and at the mines brings from 95c.@\$1.15.

Nashville, Tenn.

The several days of cold weather last week tended to give the mines in this district all the work they could handle and although at the present time the weather has again turned, the coal business is still in a fairly healthy condition.

Unless something unexpected happens, the price on all grades of fuel in the West Kentucky field seems destined to remain unchanged for the present. This means that price fluctuations will be small during the winter, if any at all.

Quotations on domestic lump in the West Kentucky fields is $1.25 per ton; nut coal, 95c. to $1, and screenings, 25@30c. The demand for steam coal has changed but little, if any.

In the two largest cities in Tennessee, Nashville and Memphis, which use coal principally from the West Kentucky field, the stocks carried by the dealers are quite small. In fact there is hardly a dealer who has over a week's or 10 days' supply in his yards. A spell of weather which would have a tendency to retard the movement of coal will find most of these dealers in a bad fix, and such conditions as this will tend more than anything else to make prices better in this field.

Indianapolis

Indiana coal operators report a spasmodic stimulation in the coal-mining business during the past week, but the recent cold snap was not of sufficient duration to bring the demand up to expectations. They say if the cold weather had continued or even been followed after a few days by another cold snap, increased demand for domestic would have resulted. The domestic trade, however, is not depended on for much by the operators. They say that enough coal can be mined in a comparatively short time to supply the demand for home use for many days. It requires continual and steady work by the large power plants to make the coal-mining business boom.

There are so many factories either closed or working short time that their demand is far below normal at this season of the year. During the first few days of the week some complaint was made because of car shortage.

Chicago

A sharp drop in temperature combined with the continued car shortage has caused a marked upturn of coal prices in the Chicago market. There has been such a restricted movement of Hocking coal that it has been possible for Western coals to sell in competition with Eastern coal at relatively the same price. Hocking Valley at $1.50 brings $3.15 f.o.b. Chicago. Leading operators of the Franklin county field have decided to advance their price to $2 a ton, owing to an unusually brisk demand.

The price of smokeless lump and egg has strengthened materially. The minimum price is $2 and some orders are being placed at $2.25. While the coke trade makes a strong showing in the domestic branches, there has not been very much change in hard cokes or furnace and foundry.

Prices direct from the mines in net tons to retail dealers and steam users on spot shipments are as follows:

	F.o.b. Mines	Chicago
Clinton:		
Domestic lump	$2.17@2.37	$1.40@1.60
Steam lump	2.00@2.20	1.25@1.45
Mine-run	1.82@2.02	1.05@1.25
Screenings	1.27@1.37	0.50@0.60
Pocahontas and New River:		
Mine-run	$3.00@3.10	$0.95@1.05
Lump and egg	4.05@4.30	2.00@2.25
Coke:		
Connellsville	$4.50@4.65	
Wise county	4.50@4.65	
Byproduct, egg and stove	4.95	
Byproduct, nut	4.55@4.65	
Gas house	4.85	

Minneapolis—St. Paul

There is a perceptible change in the coal trade all over the Northwestern States, due to the zero weather in mid-November. November 12 and 13 this year made a record for snow and blizzardy winds. While temperature was not extremely low, the high wind made it equal to 20 deg. below zero weather. This sample of cold and snow has continued for a week, and we can now say, "I told you so."

The all-rail shippers now have trouble in pacifying their customers even with every mine running to full capacity. Prices on Southern Illinois lump and egg are now held at $2 per ton at the mine, and other grades of Illinois in relative proportion. It is not thought likely that prices will go beyond this, but customers who stored coal during summer will be taken care of during the stress.

A similar condition exists at head of the Lake docks. The orders have come so thick and fast, it has been beyond both the dock companies and the railroads to keep up with the demand. Cars are difficult to obtain on the Great Northern and Milwaukee roads, especially for shipment off their lines.

St. Louis, Mo.

There has been a slight change in the local market, but it is spasmodic—up one day and down the next, depending largely upon the car supply. Conditions improved the early part of the week on practically all coals, although the advance on Standard was slight.

The local domestic trade is just fairly good—and as usual one or two large dealers who have the output of mines at a low figure are keeping the retail price down to a point where it is a losing proposition to the average operator. This applies both to the high-grade and Standard coals.

The car shortage is so severe on the Gould lines that the mines are only working from one to two days per week. On the Illinois Central it is such that the mines do not get over two to three days a week, and on the 'Frisco lines the mines are working about four days, while in the Standard field about four and a half days is the average. There is very little coal coming in from the Springfield district and the Saline and Gallatin Counties field.

The prevailing prices are:

Carterville	
6-in. lump	$1.50@1.65
3-in. egg	1.50@1.60
No. 1 nut	1.20@1.30
No. 2 nut	1.10@1.20
No. 3 nut	0.90@1.00
2-in. screenings	0.55@0.65
Mine-run	1.00@1.15
Franklin Co.	
6-in. lump	$1.65@1.75
3-in. egg	1.65@1.75
No. 1 nut	1.60@1.70
No. 2 nut	1.40@1.50
No. 3 nut	1.15@1.25
Jackson Co. (Big Muddy)	
6-in. lump	$2.25
2-in. lump	2.00
Du Quoin	
6-in. lump	$1.30@1.40
3-in. egg	1.25@1.35
No. 1 nut	1.10@1.15
Standard	
6-in. lump	$1.10@1.20
2-in. lump	1.00@1.10
2-in. screenings	0.25@0.35
No. 1 nut	0.70@0.80
No. 2 nut	0.60@0.70
Anthracite	
Chestnut	$7.20
Stove and egg	6.95
Grate	6.70
Smokeless	
Lump	$4.50@5.00
Coke, gashouse	4.65
Byproduct	5.00

Spokane, Wash.

Dealers in Spokane report no change in the local situation nor in other parts of the inland empire. The supply on hand is sufficient for domestic and factory purposes, though it is thought it will possibly be 60 days before the mines in the Crow's Nest country resume shipping extensively to this territory.

Prices are reported to be from 25c to 50c. lower this year than at the same time in 1910. Best domestic lump and nut, $8.25 to $9; anthracite, Pennsylvania, $17.50; steam coal, $6.25.

San Francisco

The arrivals of coal are not keeping pace with the consumption. Since our last report but 5831 tons have arrived from Australia and 697 tons from Seattle.

The last cargo from British Columbia arrived on Nov. 2 and another is not due from there until Nov. 20; nor can more than 3500 tons arrive from Australia before December.

Stocks held by wholesalers are quite adequate to present demands, but should the State be visited by a few weeks of cold rains, and heavy snowfall in the mountains, which would be seasonable, the consequent delays to rail shipments would reduce supplies to the danger point.

The car shortage still continues. A large accumulation of cars needing repairs is noticeable at all railroad division points. Dealers in the interior are compelled to wait several days beyond the customary time before their orders can be filled.

All prices remain the same with the exception of the Utah Fuel Company's local-yard prices, which advanced on Nov. 11 to $8.50 per short ton. Anthracite briquets have been reduced from $10 to $8.50 per short ton.

Portland, Ore.

Portland has had its first cold spell this winter. It came without notice and disappeared about as suddenly. Its duration was about a week and during that time the lowest temperature was 31 deg. above. Naturally the cold wave made quite an inroad on the fuel stored away for the season and it inspired many to replenish the supply, fearing that another cold wave may leave them short at the wrong time.

Following are the prices asked here per ton, including cost of delivery to points within the city proper:

Japanese	$7.50	
Washington lignite	$7.00@ 7.50	
Australian	10.00@10.50	
Rock Springs, Wyo	10.00@10.50	nut $9.50
Diamond, Wyo	10.00	
Carbon Hill, Wash., lump	10.50	
Carbon Hill, steam	7.50	
Newcastle, Wash	7.00	
Beaver Hill, Ore	9.00@ 9.25	
Blacksmith coal	17.00	

Production and Transportation Statistics

Kanawha Record Association

The following is a summary of shipments according to the report of the Kanawha Record Association for the fiscal year ending Aug. 31, 1911:

	Tons Coke	Tons Coal
Kanawha district	48,450	8,590,025
Kentucky district	13,020	1,247,900
New River district	198,420	6,224,900
Total	259,890	16,062,825

Railroad, Rivers and Canals

Statement of coal and coke over various railroads, rivers and canals, September and nine months ended September, 1910-1911, in short tons:

Railroads	September 1910	September 1911	Nine Months 1910	Nine Months 1911
Baltimore & Ohio[1]	3,251,239	3,194,579	27,298,982	25,385,086
Buffalo, Rochester & Pittsburg[3]	713,171	718,062	5,917,364	5,997,738
Buffalo & Susquehanna[3]	150,761	155,627	1,246,057	1,429,985

Chesapeake & Ohio Railway

The following is a comparative statement of the coal and coke traffic over the Chesapeake & Ohio railroad for the months of August, 1910 and 1911:

COAL

To	1911	Per Cent.	1910	Per Cent.
Tidewater	338,195	21	373,217	27
East	164,761	10	141,868	10
West	1,062,805	67	851,644	61
Total	1,565,761		1,367,429	
Bituminous from connections	21,930	1	6,663	1
Anthracite from connections	3,288	1	1,178	1
Grand total	1,590,979	100	1,375,270	100

COKE

To	1911	Per Cent.	1910	Per Cent.
Tidewater	330	2	4,729	14
East	10,520	54	18,771	55
West	6,002	31	8,021	23
Total	16,852		31,521	
From connections	2,706	13	2,681	8
Grand total	19,558	100	34,202	100

The Baltimore & Ohio Railroad Company

Statement of bituminous coal and coke shipments for the month of September:

	1910 Tons	1911 Tons
Coal	2,650,172	2,614,201
Coke	372,988	341,350
Total	3,023,160	2,955,551

Norfolk & Western Railroad

Coke shipments, originating entirely in the Pocahontas field, were 91,619 tons.

Production according to districts at mines on the Norfolk & Western Railroad in West Virginia for the month of October, 1911, were as follows in short tons:

	Coal
Pocahontas	1,185,594
Tug River	194,028
Thacker	206,302
Kenova	78,998
Total	1,664,922

Anthracite

The following are the monthly shipments of anthracite coal, 1910-1911:

Months	1910	1911
January	5,306,618	5,904,117
February	5,031,784	5,070,948
March	5,174,166	5,996,894
April	6,224,396	5,804,915
May	5,679,601	6,317,352
June	5,398,123	6,215,357
July	4,202,059	4,804,065
August	4,996,044	5,531,796
September	4,967,516	5,730,935
Total	46,980,307	51,376,379

Foreign Markets

Great Britain

Tonnage is still being delayed by heavy weather, and the market is quiet for prompt loading. For forward delivery prices are firm, with an improving tendency. Quotations are approximately as follows:

Best Welsh steam coal	$4.08
Seconds	3.90
Thirds	3.63
Best dry coals	3.96
Best Monmouthshire	3.66@ 3.69
Seconds	3.48
Best Cardiff small steam coal	1.92@ 1.98
Seconds	1.80@ 1.86

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth, or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½ per cent discount.

Belgium

Coal production in Belgium for the first half of the present year, ended June 30, was 11,546,970 metric tons. For the same period last year the production was 11,828,990 metric tons.

"LINK-BELT" EQUIPMENT
For Coal Mines

is Reliable because it is designed by experienced engineers, and manufactured throughout in our own shops under their direct supervision.

"Link-Belt" Coal Washeries

"The Successful Washeries"

The illustration shows the general view of the 1,000-ton "Link-Belt" Coal Washery of the Consolidated Coal Company, Saginaw, Michigan.

For list of "Link-Belt" Washery Installations, see our Book No. 111

"Link-Belt" Shaking Screen Equipments

The screen shown in the illustration is carried on rollers running in races supported on the structure, thus forming a frictionless roller bearing.

We design and build screens of all types to suit any conditions, and shall be pleased to submit plans and estimates for consideration

We also Design and Build

Tipples	Retarding Conveyors	Belt Conveyors	Box-Car Loaders
Car Hauls	Picking Tables	Crushers	Chutes, Etc.

COAL AGE

Vol. 1 NEW YORK, DECEMBER 2, 1911 No. 8

EVERY man in charge of mines believes he is traveling the road that leads to safety and economy in operation. None will claim to have reached the goal, and all will admit there are numerous routes to follow, but each aspirant is convinced that his course is the best to pursue.

Did you ever stop from your own labors, and in a moment of relaxation watch the other fellows struggling along? And did you notice as you stood there, that one well-beaten thoroughfare was crowded with men of hardened visage, scowling, cursing, jostling by?

Well, the men you saw were all struggling for safety and economy (mostly economy) in coal mining, and they were the ones who travel the road of the Bully. To their way of thinking, results can only be obtained by intimidation, and they attempt to drive, coerce and browbeat everyone with whom they come in contact.

If you were to call one of these fellows aside, he would say kindness is a mistaken virtue, tell you the men under him are an ignorant lot, and suggest that you will fail if you distinguish between the machine at the face and the man who runs it.

Such men in one way remind me of the squatters who lived in the mountains of West Virginia and Kentucky a few years ago. Many of them are still voting for Jeff Davis, and had never seen a steam locomotive until railroads were built in to develop the coal. Few of them could see through a pane of glass, or, at least, so I gathered from the fact that they always threw the window in the railway coach wide open even when it was zero weather outside. These mountaineers followed one invariable rule, "Never let the other fellow think you are afraid." They might knock your hat off, tramp on your foot, or accidentally poke their rifles in your eye, but never an apology would you hear. They were sorry in their hearts for causing you distress, but for outward expression of such feeling, you might look in vain. An apology, so they thought, would be sure indication of physical cowardice.

So it is with some mine officials; they believe that an exercise of reason, or application of "The Golden Rule" in dealing with their men, is an acknowledgment of incompetency, or inability to fill the bill as boss of the mine.

You can force up tonnage and drive down costs for a day, but such a record cannot be continually used as a pry for a better average on the day that follows. Mule-nature, human-nature, even the rope, will not stand such treatment. Moreover, when the man higher up discovers you are a whipper-in, and depend on physical force instead of mental caliber, the end will be near.

Just as the provision of good houses and pleasant surroundings will attract superior men, so will a capable humane management secure the most intelligent class of labor. It requires in the neighborhood of 700,000 miners to produce the coal needed in America each year, and it is reasonable to conclude that the man who has the most ignorant and vicious of this great army of men, will have difficulty in meeting the competition of the fellow who has secured the best of the lot.

If you honestly believe that the men under you will only respond to coercion, consider a minute whether or not the fault is your own. What reputation do you bear among your miners? Are you unreasonable, dictatorial and difficult of approach? If so, what kind of men do you expect to get in an industry that has no waiting list, and where jobs can be had for the asking?

In conclusion—safety and economy are not to be attained through the sole exercise of physical force, and mine officials who travel that road are going to find it hard sledding. Most unfortunate of all, it is difficult to convert such men—in fact, I never knew but one who did change, and that was brought about by a young mule with a five-foot reach and a two-year memory. In some ways it is a shame the mule is being replaced by the gathering motor.

A Modern Twin Coal Mining Plant

By Warren R. Roberts*

Two mines are developed through twin shafts and twin tipples. The boiler house, power plant and remainder of the equipment are shared in common. The construction of the entire plant is typical of the best modern practice and is described in detail.

*President of Roberts & Schaefer Company, consulting engineers, Chicago, Ill.

The Bunsen Coal Company, the western fuel-producing subsidiary of the United States Steel Corporation, has several operating mines in the Danville, Ill., district. It has recently purchased, and is now developing through the plant described below, a large tract of coal land, located on a branch of the Chicago & Eastern Illinois Railroad, five miles southwest of Clinton, Indiana.

It was decided to develop two seams of coal on this property, the No. 4 and No. 5, and as a matter of economy, both in regard to first cost and the cost of operation, it was decided to build a combined plant to serve the two mines and thus avoid a duplication of machinery, buildings and railroad tracks. It was not found advisable, however, to combine the tipples, as at first contemplated, and therefore two main hoisting shafts were sunk at points about 200 ft. apart, one shaft going down only to the No. 5 seam and the other passing on down through the No. 5 to the No. 4 seam. As a further economy it was decided to sink a combined air and escapement shaft for the two mines. This shaft has two air compartments and two manways, one of each running to the No. 5 level only and the others passing on down to the No. 4 seam.

As a precaution against mine accidents, a large pillar of coal was left surrounding the No. 4 shafts where they pass through the No. 5 seam. The underground development will not be discussed in this article, but it may be remarked in passing that all arrangements for both mines are most excellent, and in keeping with the character of the surface plant.

General Construction

It was the desire of the management of the Bunsen Coal Company, as expressed through their general superintendent, Clay F. Lynch, to have these mines developed along lines which would typify the best modern practice. It was also desired that, in so far as possible, and consistent with such practice, all materials used in the construction of the entire plant should be those manufactured by the subsidiary companies of the United States Steel Corporation. The Roberts & Schaefer Company, to whom were intrusted the designing and building of the complete plant above ground, adopted the following general forms of construction to meet these requirements.

The foundations for the buildings and for all machinery are of concrete. The walls of all buildings are of reinforced concrete, excepting those of the office building, which are of concrete blocks. The roofs, excepting that of the office building, which is slate, are of cement tiles laid directly on steel purlins. The roof frames are entirely of structural steel. The floors, excepting that of the blacksmith shop, are of concrete, and the window frames and sashes are of steel.

The tipples are built entirely of structural steel and have their roofs and sides covered with corrugated steel. It will be seen therefore that this plant is as nearly fireproof and permanent as the present status of the building art permits.

Fig. 1. General View of Tipples, Hoisting Plants and Boiler Plant

The combined plant for serving the two mines consists of two steel tipples and two reinforced-concrete hoisting plants, one for each main shaft. These are the only units composing the plant which it was found advisable to duplicate. The boiler plant, generator plant, shops, storehouse, miners' bath house, ventilating plant, granary, stable and office were so designed and located as to serve both mines equally well.

A general view of the tipples, hoisting plants and boiler plant, looking down the railroad tracks from the "empty yard," is shown in Fig. 1. This view was taken before the sheet-metal roofing and siding had been put on the tipples and when

some other parts of the plant were not quite complete. It illustrates fairly well, however, the arrangement of the two hoisting plants with the tipples facing each other and seven railroad tracks passing between, three under each tipple and one "passing track." The tipples are of the style termed "end pull," that is, having the engine brace running parallel with the railroad tracks. This design locates the two hoisting plants alongside of the tracks as shown. The boiler plant is placed adjacent to the No. 5 hoisting plant, and the balance of the plant, with the exception of the stable and granary, is on the hillside in the rear of the boiler house.

Fig. 2. View of Twin Tipples under Construction

The Steel Tipples and Boiler Plant

A view of the twin tipples, looking up the railroad tracks, is shown in Fig. 2. This photograph also was taken before the sheet-metal roofing and siding were in place, in order to illustrate the equipment.

The tipples are substantial steel structures and contain the usual Indiana equipment, consisting of self-dumping cages, standard Akron bar screens above the weigh hoppers; weigh-hoppers for weighing screened lump and a pair of the Roberts & Schaefer Company's standard roller shaker screens for making screened coal and loading on three railroad tracks. All this equipment is of the best construction and has every convenience for changing the grades of coal.

The steel trestle connecting the two tipples, shown in this view, is for handling mine cars and all necessary supplies to and from the No. 4 shaft across the railroad tracks to the shops and storehouse, which are located on the same side of the tracks as the No. 5 shaft.

An end elevation of the boiler plant and a view of the concrete smoke stack during construction are given in Fig. 3. The general construction of the boiler house is uniform with that of all the other buildings, as described in the beginning of this article. Attention is specially invited, however, to the large windows with steel frames and sash.

The smokestack seen in this view is built entirely of reinforced concrete and is 10 ft. in diameter on the inside and 175 ft. high. It is connected with the boilers by a steel smoke flue and is lined for 50 ft. above the top of the flue with firebrick.

Fig. 3. Boiler House and Stack, under Construction

The method of constructing this stack is particularly well shown in the illustration. The materials were taken in through an opening in the bottom and hoisted up through the inside by means of the tower, above the stack. The vertical reinforcing rods are shown and also the movable forms used for holding the concrete.

An interior view of the boiler house is given in Fig. 4, which shows the coal bunkers for receiving and storing the slack coal used for feeding the boilers. The steel chutes for delivering the coal from the bunkers into the stokers may be seen in the farther end of the view. These coal bunkers, including all supporting columns, braces, etc., are entirely of reinforced concrete. It will be noted from this view that the boiler room is unusually light. This condition was obtained by having ample window space as illustrated in Fig 3, and by placing the coal bunkers high enough above the windows to prevent their shutting out the light.

This view also shows the four 375-h.p. Stirling boilers and the chain-grate stokers, all in the process of construction. Room has been provided for two additional boilers when the development of the mines warrant their installation.

There is a concrete tunnel beneath the rear of all stokers, extending throughout the length of the boiler house and a distance beyond sufficient to enable the ashes to be taken in a car directly from the ash hoppers below the stokers to a hoist outside, and thence, by an ash-handling equipment, to a dumping ground at some distance from the plant.

Coal is delivered to the bunkers from beneath the slack screens in the tipples by coal conveyers. By the installation of these conveyers and the stokers, the coal is handled by machinery directly from the mines into the boilers without any hand labor whatever. The ashes also are handled entirely by mechanical means.

The Power Plant

The general appearance of all the buildings composing this plant (excepting the office) is shown by the view of

the boiler house given in Fig. 3. This view shows the concrete foundations; the reinforced-concrete walls; the cement-tile roofing and the steel window frames and sash. These buildings are not intended to have any architectural features, but care was exercised in their design to make the proportions and general lines as good as possible.

Fig. 5 is an interior view of one corner of the generating room, showing two of the 250-kw. direct-connected generators, also the switchboard, some of the steam piping and the five-ton overhead crane used for handling equipment in the power house. It will be noticed that the engines driving the generators are of the four-valve Corliss type. This in indicative of the class of machinery and equipment used throughout the entire plant, showing that within certain reasonable limits the first cost was increased for the purpose of securing economy in maintenance and operation.

The combined shop building for the two mines, containing three compartments, one each for the carpenter, blacksmith and machine shop, is shown in Fig. 6. This building has an ample ventilator, the portion over the blacksmith shop having louvers and the portion over the carpenter and machine shops having pivoted windows. It will also be noted that the windows, instead of being made into an upper and lower sash, as is usual, have the main sash made stationary and contain two small, pivoted sashes. This is an improvement over the old arrangement, inasmuch as it enables the main sash and frame to be built into the walls and weatherproofed and leaves only a small window loose.

Miners' Bath House

There is a general tendency on the part of the better class of mining companies to go beyond the mere letter of the law in providing wash houses for their miners. Experience has taught that there is really small benefit to the miner in appearance or comfort, when simply provided with a wash basin and water. If he is to improve his appearance upon coming out of the mine and be presentable while passing along the streets to his home, he must be provided with facilities for properly washing and bathing himself. Where coal companies have provided such facilities there seems to have been a commendable spirit upon the part of the miners to make use of them.

Based on the experience of the Frick Coke Company and other fuel-producing subsidiaries of the United States Steel Corporation, the Bunsen Coal Company has taken a step in advance of other Indiana operators and provided at this plant excellent facilities in the way of a modern miners' bath house.

The building illustrated in Fig. 7 is some 32x62 ft. in size, and is built of reinforced concrete with concrete floors and cement-tile roofing. The roof is of open steel construction, allowing the superheated air in the building to pass up and out through ventilators. The building is provided with plain, substantial, wooden benches for the use of the men in changing clothing and with ample facilities for washing and with shower baths. The entire interior construction is such that the building may be washed out by the use of a hose and the water

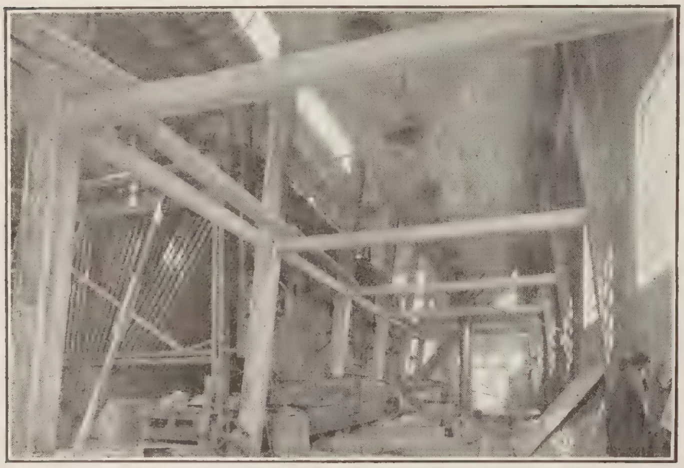

Fig. 4. Interior of Boiler House, Showing Concrete Coal Bunkers

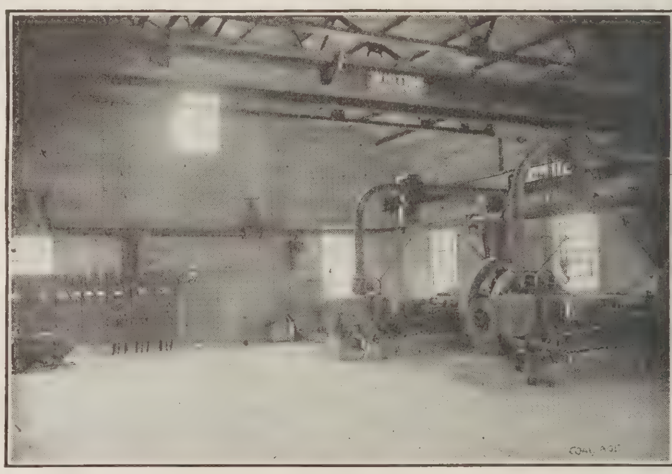

Fig. 5. Interior of Power House, Showing One Corner

Fig. 6. Blacksmith, Carpenter and Machine Shop

Fig. 7. Miners' Bath House, During Construction

drained off to the sewer. This latter facility enables the attendant to keep it always in a cleanly and presentable condition.

Ventilating Equipment

The ventilation for both mines is supplied through separate air compartments forming a single shaft, as explained in the beginning of this article. The fan is a Clifford-Capell, 20 ft. diameter by 5 ft. 6 in. wide, designed to run as a blowing fan but made reversible. It is driven by a pair of four-valve Corliss type engines direct connected to the fan shaft by clutches. These engines are placed one on either side of the fan and each engine has sufficient capacity to drive the fan under ordinary working conditions. In case of an accident to either engine the other is available; or in case of emergency, where unusual demands are made on the fan, both engines can be connected.

The casing for the fan wheel and the connection to the air shaft are entirely of steel plate. The balance of the housing, the roofs, side drifts, engine houses, etc., are entirely of reinforced concrete.

Mine Office

In providing comforts and conveniences for the superintendent, engineer and general mining force, this company has also gone beyond the usual custom by erecting a most excellent office building. It is a two-story structure, 30x40 ft., built of cement blocks with slate roof and has a large porch on the front which gives the building a pleasing and substantial appearance.

The plain reinforced-concrete walls adopted for the other buildings were not considered appropriate for the office building, where an architectural effect was desired. The results obtained with the cement blocks are quite satisfactory.

The interior finishing and furnishings of this building are plain but substantial and in keeping with its character. The rooms are all steam heated and electrically lighted and the sleeping compartments are provided with bath, toilet, etc.

Penn Mary Coal Mines, Heilwood, Pa.

By R. Dawson Hall

The equipment in these mines has some important features not duplicated at mining plants elsewhere. A low-pressure turbine is installed to use the exhaust steam from all the reciprocating engines previously installed at the plant.

The Penn Mary mines of the coal company of the same name are remotely situated from all main lines of communication. A winding branch, designated after its terminal, Possum Glory, connects through the Cherry Tree & Dixonville Railroad with the line of the New York Central & Hudson River Railroad. The town of Heilwood is on the boundary line between Cherry Hill and Pine townships, in the center of the eastern part of the county of Indiana, Penn.

Geology

For the most part all over that county, the Allegheny series of coal measures lie entirely below water level and are hard to reach, but across the Indiana field is a long, irregular scar where the elevation of the measures and the erosion of the streams have combined to lay bare the upper members of the Allegheny beds, to wit, the Upper and Lower Freeports. It is interesting to note that the butt and face cleavages of the coal are not distinct. The ragged-edged scar seems to embrace both the Chestnut Ridge Anticline and the Brush Valley Syncline, together with the valleys of Two Lick and Yellow Creek and their unimportant tributaries.

The mines of the Penn Mary Coal Company are in the Lower Freeport seam. This is about 42 in. thick, but of this about six inches in the bottom is not desirable. There is, therefore, the usual difficulty in getting a large production and sufficient men. On the whole, considering the thinness of the seam and the remoteness of the town, both difficulties seem to be admirably met. The large interval of about 75 ft. between the Freeports is maintained here as in the other parts of Indiana county, though the upper measure at this place is not of workable thickness.

Motors on Steep Grades

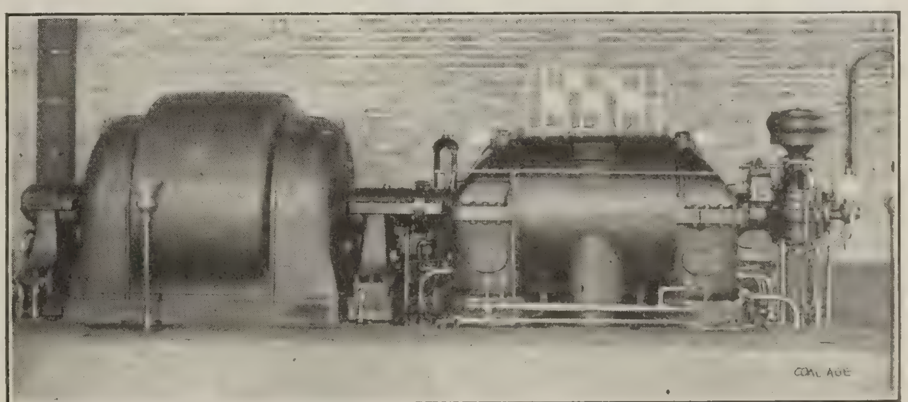
The Freeports at Heilwood are marked by awkward dips, which make drainage and haulage alike troublesome. Beside this, there are the heavy pitches away from the Nolo Axis. Thus the main haulage road of Penn Mary No. 1 dips with much irregularity on an average grade of 5 per cent., while No. 3 has a grade of 16 per cent. against the load. These uneven dips are not well suited to engine planes, though a tail-rope or a continuous-rope system might be adopted.

The method followed has been to use motors assisted by electric hoists, using the motor on entering the mine to unreel the rope and pull the cars where the downgrades slacken, and, on coming out, to help pull the trip; the rope and the motor mutually aiding each other. This manner of operation is proving satisfactory. When the trip is detached from the rope the motor is ready to perform the work required on the level stretches and by using a hoist wherever needed the motor never has to double and never burns out on the heavy lifts. As many as 75 cars per trip are pulled out of Penn Mary No. 1, but only 10 can be pulled out of No. 3.

Heilwood Village

It is not the intention to describe Heilwood. It is a model town in all respects, well laid out and clean. It has a hospital better than many a town of ten thousand inhabitants and in Doctor McHenry, a company physician with an enthusiasm in his work which is back of many of the provisions for the sanitary improvement of the town.

The company is now building two mine-rescue buildings, one at tipple No. 1 and one at tipple No. 2. Each building will house two Draeger helmets of two-hour capacity and one half-hour apparatus of like make. There will also be a Pulmotor in each building.



Westinghouse Parsons Low-pressure Turbine with Generator

At present, tipple No. 1 is making 1200 tons per day. Tipple No. 2 drawing from 2, 3, 4 and 5 mines, handles 2250 tons. Tipple No. 3, is handling 650 tons of coal from No. 6 mine. A new tipple is to be built to handle the coal from mine No. 7. The tonnage could be doubled if necessary at these plants. The main feature of interest in the plant centers around the electrical equipment, in charge of B. F. Smith, chief electrician and master mechanic.

Older Electrical Equipment

The original equipment, constituting the direct current side of the power house, consists of four complete units, all 200-kw., 250-volt, 800-ampere generators, driven at 225 r.p.m. by four 16x18-in. Fleming engines, of the Harrisburg Foundry and Machine Works. The Rochester forced-feed oiling system is used on these engines and with this arrangement there is no risk of the attendant being burned by the bursting of sight-feed oil gages. It is said that the installation of these lubricators effected a saving of $3 every 24 hours in the oiling of the four engines. This saving would doubtless not be as marked now as it was when the change was made, because at that time, the boilers were inadequate for the work imposed on them, the steam was therefore exceedingly wet and a large proportion of the oil used was carried off by the moisture without reaching the cylinder walls.

Each generator unit is supplied with a Vermont-marble switchboard panel and the general distributing system is protected by six Westinghouse double-pole circuit breakers mounted on four panels which are uniform in construction with the others mentioned. All the electrical machinery in use at the plant was furnished by the Westinghouse Electric and Manufacturing Company.

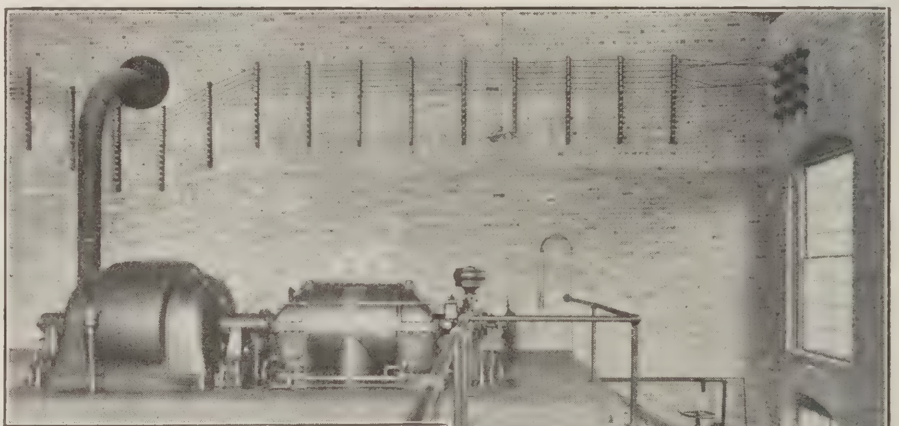
Low Pressure Turbine

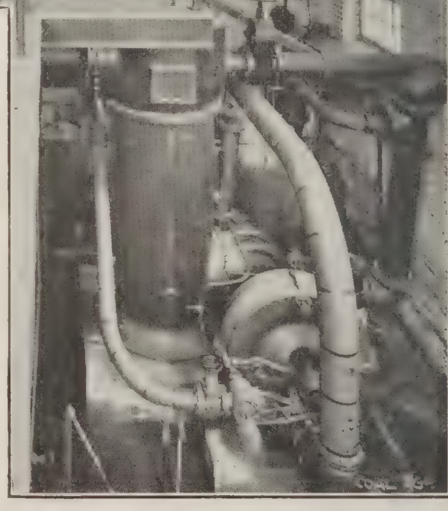
The exhaust from the high-pressure engines in the direct-current section of the power plant, together with that from all auxiliaries around the central station is conducted to a Westinghouse-Parsons turbine which drives a 3-phase, 60-cycle, alternating-current generator, mounted on the same shaft with it at 3600 r.p.m. The latter has a rated capacity of 750 kv.a., 2400 volts, and 180 amperes per terminal.

A 25-h.p., shunt-wound direct-current motor, running at 1100 r.p.m., on 250 volts and 86 amp., actuates the exciter of the turbine generator. This exciter unit is a 15-kw. generator, producing 120 amp. at 125 volts pressure.

A No. 13 LeBlanc condenser takes care of the exhaust from the low-pressure turbine and produces a vacuum of 26.5 in. of mercury, that is, the back pressure from the condenser together with the weight of a column of mercury 26.5 in. long would equal the atmospheric pressure.

This condenser, Fig. 2, is of extremely simple construction. An illustration showing the outside appearance will be found on the front cover and a sectional view can be seen in the body of this article. A pipe *A* connects the top of the condenser with a large tank of water outside the building. This tank is termed the "cold well." The low pressure established in the condenser serves to draw the cold water continuously through the pipe *A*. The water passes through the spray nozzles *B*, mingling with the exhaust steam from the turbine which enters at *C*, and the resulting hot water is collected in the chamber *E*.





Low-pressure Turbine with Condenser

The condensation is rapid and reasonably complete, but extremely low, absolute pressures cannot be obtained by this device alone, because the exhaust steam and the cold condensing water both contain air and no simple condenser, unaided by mechanical means for removing this air, can possibly succeed in producing even an approximate vacuum.

In some systems a more complete vacuum is sought by the use of reciprocating air pumps. The objection to this method of evacuation is to be found in the necessity that always exists in a reciprocating engine to provide for a clearance space at the end of the cylinder. The LeBlanc condenser proceeds on a principle similar to that of the Sprengel air pump which is as perfect a rarefier of air as any known. Whereas in the Sprengel pump discontinuous drops of mercury in a narrow tube impel the air forward and out of the receptacle to be evacuated, in the LeBlanc pump, water is used, and the discontinuity of its discharge is obtained by the use of a wheel, section *N N*, Fig. 2., the vanes of which are filled with water from the port *H* which is in turn filled from the stationary chamber *G*.

The mixture of air and steam in the upper part of the condenser *E* is taken by the pipe *D* down past the edges of the blades of the rotor of the so called air pump *P*, which is driven in the direction of the arrow. The water driven discontinuously from the blades of this wheel entrains the air and steam in the narrow passages *F*, into which the water is forcibly discharged. Thus an efficient vacuum is obtained. The air pump is operated by a steam turbine using live steam from the boilers. Mounted on the same shaft with both air pump and turbine is a centrifugal pump for removing water from the condenser to the hot well.

The three units are inclosed in a common case and are of a construction so simple that they can scarcely get out of order. There is a side passage *L* in the discharge *J* from the air pump by which steam can be admitted to start the condenser after a shutdown, but this is not necessary where, as at Heilwood, the cold well is over 3 or 4 ft. above the basement floor on which the condenser rests. It is said that the small live-steam turbine, for driving the two pumps, requires only about 2 or 3 per cent. of the power delivered by the main engines.

Distributing of A. C. Current

The alternating-current switchboard consists of five panels, one fitted for two exciter units, one a blank for future development, one equipped for the present 750-kw. low-pressure turbine outfit, one equipped with two present distributing circuits and one a blank panel for use

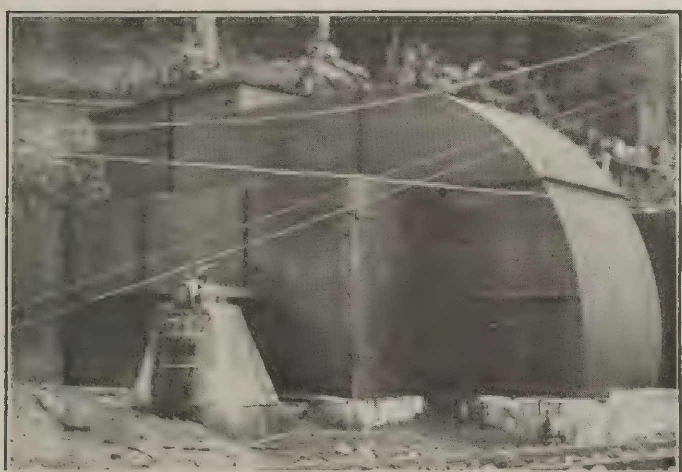
when other circuits have to be distributed. A Tirrell regulator is employed to maintain a constant voltage.

The transmission lines to the substation at tipple No. 2 are of No. 1 hard-drawn copper wire, supported on chestnut poles set 120 ft. apart. The line is protected from lightning by a No. 6 soft-drawn wire which is strung from end to end and connected to the ground at various points. This arrangement has has given excellent satisfaction.

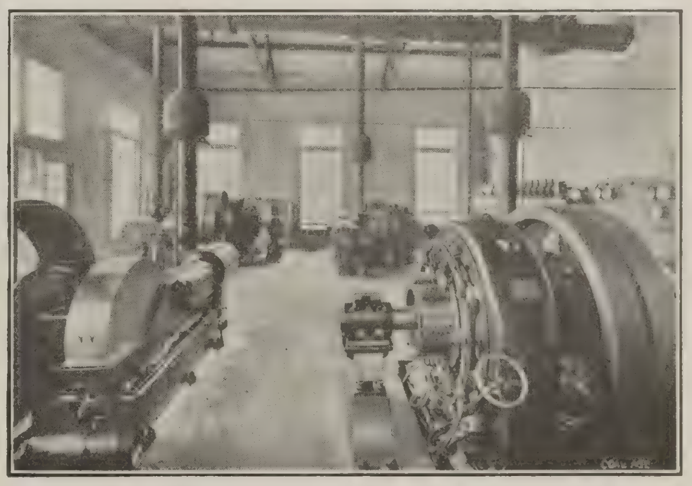
The First Substation

A substantial substation of brick has been erected near tipple No. 2. This contains a motor-generator set consisting of a 450-h.p. synchronous motor, running at 900 r.p.m., which receives a current of 94.1 amp. per phase at 2200 volts potential and a 300-kw. direct-current interpole generator delivering 1200 amp. at 250 volts.

Electric Rock Larry. Capacity 10 Tons



Fan Near Tipple No. 2



Direct-current Engine Room, Heilwood, Penn.

The exciter for this outfit is a 4½-kw. machine, rated at 36 amp. and 125 volts at 900 r.p.m. The plant is reversible. The direct-current machine can be supplied with direct current from the power station and thus drive the alternating-current motor as a generator to supply alternating current for the town houses and street lighting, and for the fans. Ordinarily the a.c. generator can be run either in parallel with the four d.c. generators at the main station or it may be run as an independent plant.

Lightning arresters with choke coils are located at the substation together with oil circuit breakers for the alternating-current lines; also a circuit breaker and switches for the direct current. All mines except No. 5 can be cut out at the switchboard of this substation. The motor-generator set is brought up to speed by running the d.c. generator as a motor and not by induction-motor action in the a.c. machine.

By regulating the field of the a.c. synchronous motor, the power factor of the circuit can be adjusted to unity. James Lytle is the acting electrician at Penn Mary, under the direction of Mr. Smith.

Electrical Hoisting

There are two 200-h.p., Lidgerwood hoists, a steam hoist at No. 1 and an electric hoist at No. 3.

The following tables show the cost sheets of the two latter for labor and material. The labor item does not include the wages of the operator, which is the same at the two hoists. Of course, the power cost is not considered in this estimate.

Running Cost of Steam Hoist

	Material	Labor	Total
August, 1911.....	$29.19	$23.60	$52.79
September, 1911.	8.04	13.60	21.64
October, 1911....	7.77	6.58	14.35
November, 1911..	2.51	0.77	3.28
Total.........	$47.51	$44.55	$92.06

Electric Hoist

	Material	Labor	Total
August, 1911.....	$4.64	$0.00	$4.64
September, 1911.	7.70	0.00	7.70
October, 1911....	0.00	0.00	0.00
November, 1911 .	0.00	0.00	0.00
Total	$12.34	$0.00	$12.34

In connection with the haulage motors on steep grades, as has been mentioned, small hoists are used of 5-h.p. capacity, running at 725 r.p.m. and taking 22.2 amp. at 250 volts.

Fans, Mining Machines and Motors

The fan at Penn Mary No. 1 is a 16-ft. Capell fan. No. 3 mine is ventilated by a J. C. Stine fan 12 ft. in diameter, driven by a 100-h.p. induction motor running at 690 r.p.m., receiving 3-phase, 60-cycle current at 2000 volts potential and 27 amp. per terminal. Electric power is being used for eight 12-ton and four 15-ton Baldwin-Westinghouse locomotives; also for thirteen Pneumelectric punchers and one Hirst electric rotary cutter, which are used for undercutting the coal. Electric pumps with wood-pipe discharge lines are installed at appropriate places in the mines.

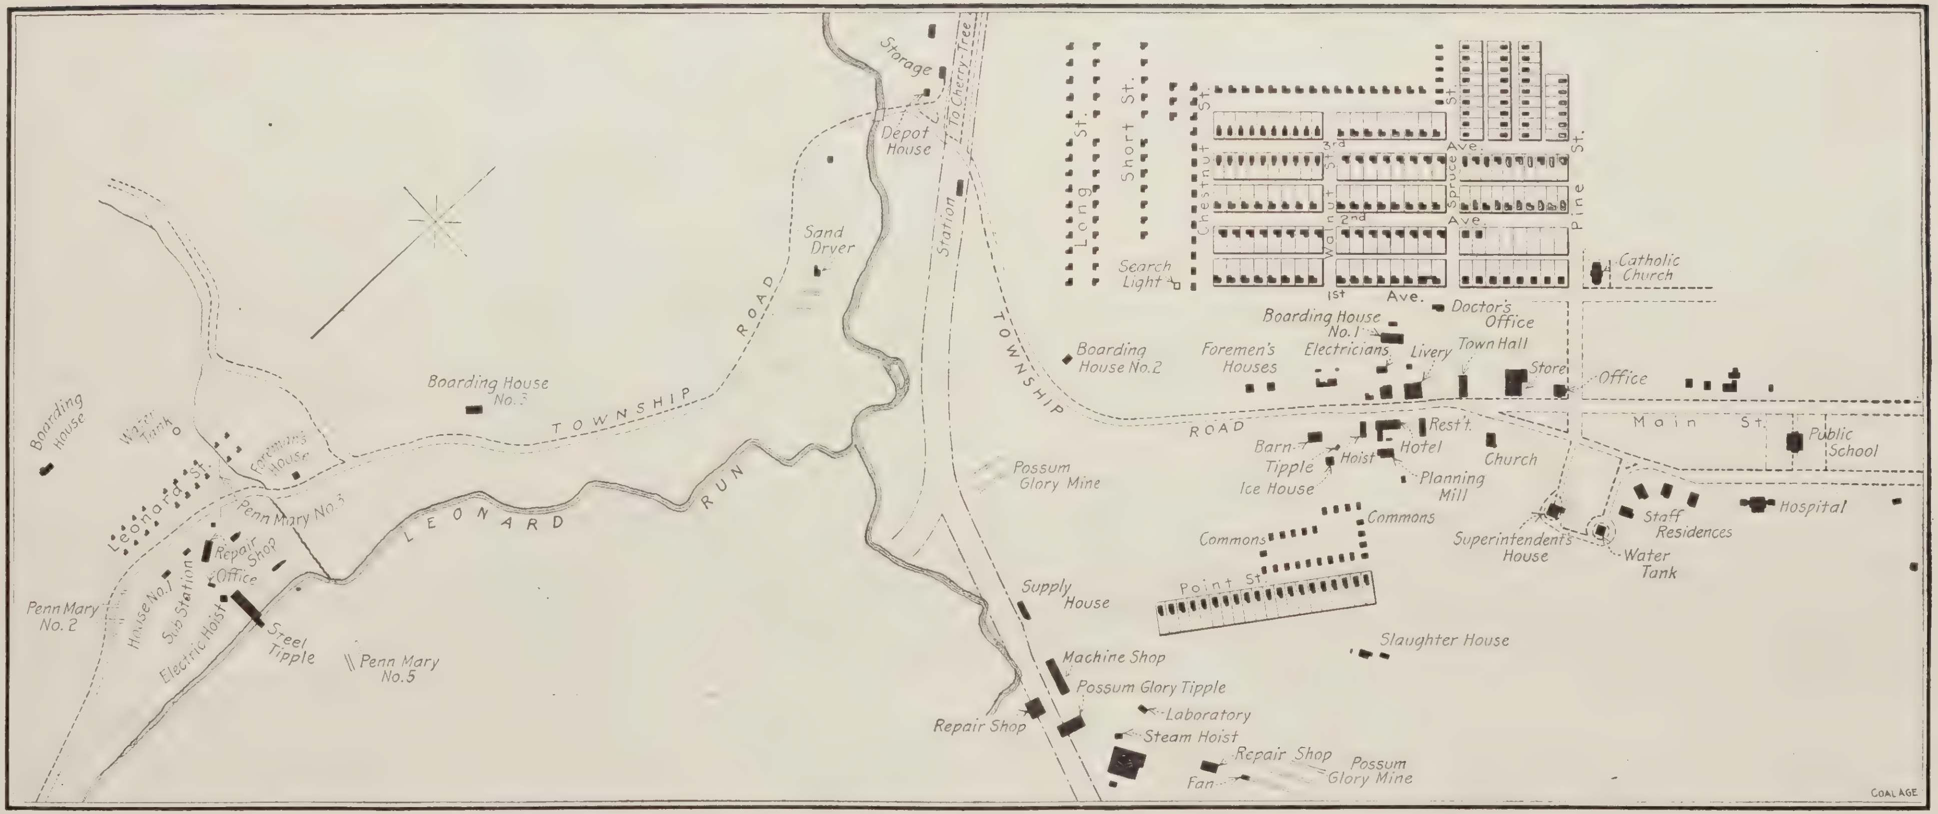
Boiler Equipment

The boiler equipment consists of six 300-h.p. water-tube units, four of which are Babcock and Wilcox boilers, the other two being built by E. Keeler, of Williamsport, Penn.

The feed-water supply to the boilers is controlled by Cope boiler-feed regulators and pump governors. Under ordinary conditions the water level is so maintained by these devices that it does not vary more than an inch from the desired elevation in the boilers.

Fuel is brought to the firing floor in Ernst Weiner steel cars filled from chutes at the side of the boiler room; these run on tracks in front of the boilers, making the work of stoking light and keeping the space in front of the boilers clean.

Two Smith-Vaile steam pumps, 14x10 x18 in., either of which is adequate to supply the power house and town, pump water from a reservoir on Yellow creek, a distance of about 1000 feet. As an auxiliary supply two drilled wells take water from the sandstone above the "B" bed. One of the pumps is located in the boiler house and one about 100 ft. away.



Map Showing Location of Penn Mary Mines and Surface Buildings, Heilwood, Indiana County, Penn.

This last pump is arranged so that when the water in the tank reaches a predetermined level, a switch is automatically thrown which breaks the circuit to the motor by which the pump is driven. This switch is operated by a float in the tank.

Compressed Air

Except as used in the Pneumelectric punchers, the only considerable use of compressed air at the plant is in the large machine shop of the Penn Mary Coal Company. Here, air is used to operate the power hammer, and is supplied by three standard Westinghouse locomotive-type steam-driven air pumps 9½x9½x10 in. in size. The line pressure for the service is 75 lb. per sq.in. The air is used also to some extent for general cleaning in the power house. All the auxiliaries of every sort driven directly by live steam furnish their quota of exhaust to the low pressure turbines so that no power is wasted.

Chemical Laboratory

The water used is analyzed every week by the chemist, C. W. McGregor. All oils, cements, and paint used are also analysed. In preparing the coal for analysis it is ground to such a fineness that it will pass a 100 mesh, by means of a disk pulverizer, made by the Denver Fire Clay Company. This is driven electrically by a direct-current motor of 2 h.p., running at 1200 r.p.m., and using 9 amp. at 220 volts. The grinding is performed on the face of the revolving wheel, the distance between the wheel and the friction plate being regulated by capstan screws. The coal escapes through small slots in the grinding face.

Rock Disposal

The question of rock disposal is made difficult by the thinness of the coal and the fact that it outcrops low down in narrow valleys. A large quantity of rock has consequently to be taken a long way from the drift. The rock is dumped from the tipple into a large 10-ton electric larry. This larry has a bottom sloping toward the two sides and also toward the rear end. It is run backward onto the dump. Large doors on the sides and rear of the larry are opened by a simple lever, and once released the rock falls without further assistance from the car, unloading in three directions.

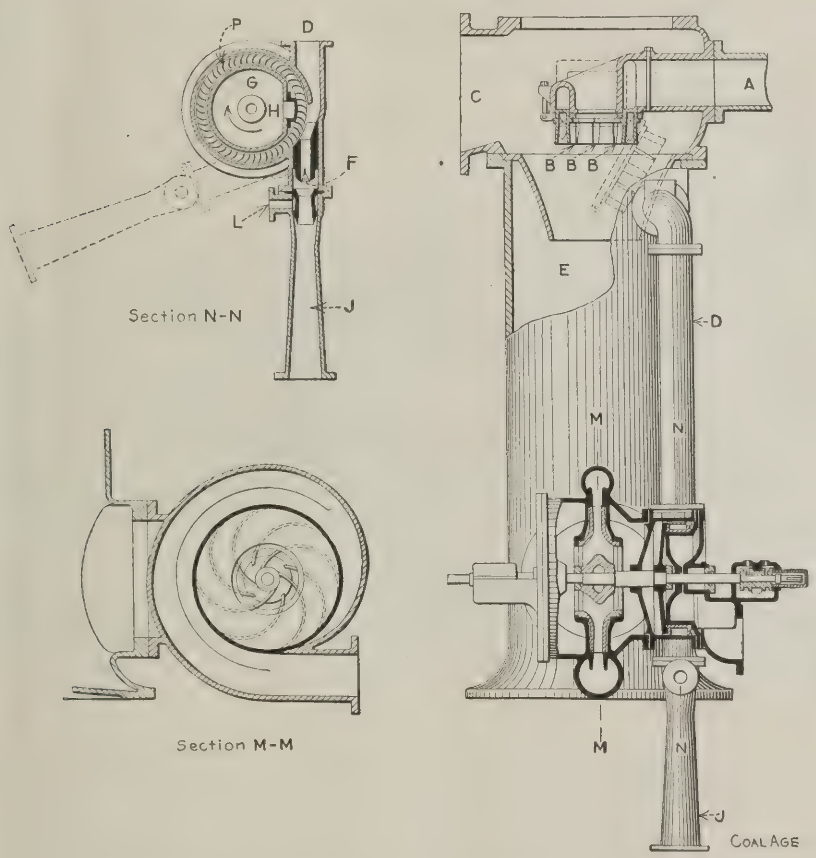
Blacksmith Shop

A large blacksmith shop is equipped for the manufacture of mine cars and for all simple repairs to machinery. As a guide to those who may have to equip such a shop the following figures are given. The shop measures 32x138 ft.

The motive power is furnished by a 30-h.p. motor, run at 600 r.p.m. on 115 amp. and 220 volts. The plant includes:

One 22-in. x 10-ft. lathe for general work.
One 26-in. x 12-ft. lathe for turning axles.
One 38-in. x 16-ft. wheel-turning lathe.
One 18 in. x 5-ft. planer.
One 25-in. radial drill press.
One 30-in. radial drill press.
One 5-ton air hammer.
One bulldozer for preparing car irons.
One 14-in. power hacksaw.
One combination shear and punch.
One pipe machine to cut and thread from 1¼- to 6-in. pipe.
One 1-ton triplex block in car-repair shop.
One 1-ton Triplex block in machine shop.
One 2-ton Triplex block in machine shop.
One double-spindle, 14-in. emery-wheel stand.
One 3-ft. grindstone.
Two forges, one driven by a 30-in. Buffalo blower and one by an 18-in. Champion blower.
One heating furnace for preparing iron for the bulldozer.
And for woodworking:
One 36-in. band saw.
One 14-in. rip saw.
One 16-in. cutoff saw.

The machine shop, while in general charge of Mr. Smith, is under the direct supervision of William G. Davis.



Showing Details of the Le Blanc Condenser

The general management of the operation is in the hands of H. P. Dowler, assisted by M. H. Kalloway. The mining engineering is directed by John T. Hoover. To these and all those whose names have been already mentioned I desire to make acknowledgment for assistance in preparing this article.

The railroad is being extended to tipples 3 and 4, and some time next spring these important additions to Penn Mary will be shipping coal. It was in anticipation of these further developments that the a.c. electrical installation was provided.

Winter Meetings of the Mining Institutes

The West Virginia Coal Mining Institute will hold its winter meeting at the Masonic Temple, Fairmont, W. Va., on Dec. 4, 5 and 6. The program includes a number of addresses on subjects of great interest to the coal-mining fraternity in general as well as several dealing with more particularly local matters. An interesting feature of the meeting will be the tour of inspection to the coal mines and industrial plants in the neighborhood of Fairmont, on Wednesday Dec. 6, under the auspices of the Fairmont Chamber of Commerce.

The following addresses will be given: "A Mine Foreman," John Laing, chief of the department of mines, Charleston, W. Va.; "Forestry for Mining Companies," R. C. Eggleson, forester, Consolidation Coal Company, Jenkins, Ky.; "The Relationship of Manufacturer to Operator," F. C. Albrecht, E. E., Westinghouse Electric & Manufacturing Co., Pittsburg, Pa.; "A Method of Testing for Black Damp," W. R, Crane, E. M. Dean, School of Mines, Pennsylvania State College, State College, Pa.; "Technical Education with Special Reference to Mining Interests," Dr. Thos. C. Hodges, president, West Virginia University, Morgantown, W. Va.; "A History of the Fairmont Region," Ex. Gov. A. B. Fleming, Fairmont, W. Va.; "The Recovery of Coal from the No. 2 Gas Seam, in the Kanawha District," James J. Marshall, chief engineer, Loup Creek Colliery Company, Page, W. Va.; "The Economical Production of Steam in the operation of Coal and Coke Plants," Chas. N. Hays, Pittsburg, Penn.

On Monday, after the president's address, Judge W. S. Haymond and Hon. E. M. Showalter will welcome the Institute. Five minute responses will then be in order from a number of prominent members. The Fairmont Chamber of Commerce will tender a banquet on Tuesday, Dec. 5. Frank Hass, Fairmont, W. Va., is president of the Institute and E. B. Day, Pittsburg, Pa., is secretary-treasurer.

Coal Mining Institute of America

On Dec. 19 and 20 a joint session of the Coal Mining Institute of America and The Engineers' Society of Western Pennsylvania will be held in the rooms of the latter organization, Oliver building, Pittsburg, Penn. This is the regular winter meeting of the mining institute.

Addresses will be delivered by Walter Riddle, Ph. D., president of the Engineers Society, and by S. A. Taylor, president of the mining institute. Mr. Taylor's subject will be "The Coal Fields of the World, with Some Statistics and Data Thereon," and will be illustrated by stereopticon. The institute dinner will take place in the evening of Dec. 20, at the Seventh Avenue hotel.

The following papers will be presented: "Power Plants with Special Reference to Requirements in Western Pennsylvania" (illustrated with lantern slides), O. S. Lyford, Jr., R. W. Stovel, engineers with Westinghouse, Church, Kerr & Co., New York City; "A Remarkable Coal Formation," Jesse K. Johnston, Charleroi, Penn.; "Special Methods of Testing for Mine Gases," W. R. Crane, Ph.D., dean The School of Mines, Pennsylvania State College; "The Construction and Maintenance of Telephone, Signal and Trolley Lines in Mines," E. M. Weir, Western Electric Company; "Application of Gas Analyses in Coal Mines," G. A. Burrell, chemist, U. S. bureau of mines; "The Price of Coal Compared with the Price of Materials Used in Mining," E. N. Zern, assistant professor of coal mining, University of Pittsburg; "Electrical Symbols for Use on Mine Maps to Indicate the Character and Location of Electrical Apparatus, H. H. Clark, electrical engineer, U. S. bureau of mines; Mr. Randolph, of Wood & Randolph, electrical engineers, Pittsburg; "Lignite Mining in Colorado," C. J. Griswold, assistant professor of mining, Carnegie Technical School, Pittsburg.

Coal Mining Methods in Michigan

By R. B. Hosken*

An interesting description of mining methods in Michigan in which the use of machines in low seams is discussed. The coal beds range from 26 to 42 in. in thickness and have a poor roof. Unusually large quantities of water are encountered.

From an economic standpoint, Michigan is a small factor as a coal-producing State. In 1909, its production, about a million and three-quarters tons, placed it twenty-third in the list of coal-producing States, below Montana, Arkansas, Utah and Texas. In 1910, the tonnage was reduced to 1,473,874, and but 2474 workmen were employed in this industry.

The student of coal-mining conditions and methods, however, can well afford the time needed for a closer glance at the Michigan situation than these figures would seem to warrant. With the exception of the extreme northern part of the Appalachian region, the Michigan coalfield is the only one within the drainage area of the Great Lakes. It covers some 6500 to 8000 square miles, the seams having an average thickness of about 26 in. No coal is mined less than 2 ft. thick at present, and of this there are estimated to be about eight billion tons still unmined. Active mining is confined to the eastern portion of the field in a line drawn between Bay City and Jackson; and Bay and Saginaw are the two counties in which the bulk of the coal is produced. Small tonnages are credited to Clinton, Eaton, Genesee, Ingham, Jackson, Shiawassee and Tuscola counties.

Coal mining was reported in Michigan as early as 1835; but for many years wood remained the chief fuel for both domestic and industrial purposes. It was 1898 before the tonnage rose to the quarter million mark, and the maximum output thus far was that of 1907, amounting to a little over two million tons. Development has been slow, and no very great increase can be looked for, owing to the competition encountered from West Virginia and other larger fields. Nearly the entire production of the State is used locally, therefore, and some of the mines operate only during the fall and winter months, when the domestic trade affords the best prices.

Fig. 1. Power House and Tipple at Beaver Mine, Bay City, Mich.

Geology

Geologically, Michigan coal seams are correlated with the Lykens Valley group of the Pottsville series and the lower carboniferous formation in Pennsylvania and Ohio. The beds vary greatly in different parts of the field. They lie horizontally, but in some cases local undulations, called "rolls" or "swamps," are found, which increase the difficulty of mining. The depths of the seams from which the heaviest production now comes, are from 130 to 175 ft. The beds overlying the coal are chiefly weak black shales, making poor roof. Black bituminous limestone, full of shells, or wet sandstone are also found as roof. The bottom is usually fireclay or a soft sandstone, and the mines, as a rule, lie beneath low ground and are wet.

The coal itself varies considerably in hardness. In some mines it is soft and friable, breaking up easily. In other portions of the same bed where the seam is thinner, the coal is much harder, and rolls out in firm blocks, after being undercut.

The seam which is especially considered in this article is about 145 ft. from the surface, and the following is an average analysis: Specific gravity, 1.26; moisture, 10.67; volatile matter, 33.59; fixed carbon, 53.80; ash, 1.94; sulphur, 1.01; British thermal units, 13,000.

It will be seen from this rough summary that mining problems and methods will vary in detail in nearly every mine. In general, however, the method of operation is uniform.

System of Mining

The mines are opened by double-compartment hoisting shafts with an air shaft 300 to 500 ft. distant. In this latter there is a separate manway or escapeway compartment with spiral staircase.

The underground workings are laid out on the double-entry system, with a pillar

*Engineer, 1459 Olive avenue, Chicago, Ill.

18 to 25 ft. thick between the haulage road and the air course, which are from 8 to 15 ft. in width and from 5 to 6 ft. high (necessitating brushing the roof and lifting bottom). Crosscuts are made at intervals of 40 or 50 ft. These are closed up and made airtight as the entry advances, to maintain proper circulation of air. Cross entries and air courses are driven at right angles to the main entry, 300 to 400 ft. apart.

Rooms are turned from the cross entries on 40-ft. centers, and in machine-operated mines are carried 30 ft. wide. They are driven 150 to 200 ft. deep to meet the corresponding room from the next succeeding entry. Breakthroughs for ventilation between rooms are 6 ft. wide, and are spaced not over 60 ft. apart. The room necks are 8 ft. wide. They are kept in good order and especial care is given to the haulageways. These are timbered with crossbars in the entries, and in rooms, when necessary. The curves are carefully laid, to prevent delays to cars or mining machines.

Ventilation and Haulage

Blowing fans of various patterns are used in the Michigan field. Slow-speed types are the rule, as the mines are not sufficiently developed to make the ventilation problem a large one. The air current is forced down the air shaft, through the air courses and working places, and back via the haulage road to the hoisting shaft, which is, therefore, the upcast. This arrangement is a convenient one, as it keeps the hoisting shafts free from ice in the winter months. The current is usually reversible, in case of emergency, by opening and closing doors in the fan casing.

The pit cars are of wood, and hold from 750 to 1000 lb. of coal each. They are pushed to and from the face in the rooms by hand, and collected in the entries and hauled to the shaft bottom by mules. Power haulage has not been generally adopted as yet, because of the small area of the workings. In the No. 2 mine of the Robert Gage Coal Company, at St. Charles, the trips are hauled from partings on the cross entries to the bottom by electric locomotives. Rope haulage is employed at the No. 5 mine of the same company, at Auburn. Self-dumping cages deliver the coal direct to shaker screens.

Mines Have Poor Roof

As already noted, mining in this field is handicapped by poor roof, a large amount of water and thin seams, which range from 26 to 42 in. in hight. Timbers must be placed at frequent intervals and brought close up to the working face; and with drainage represents a heavy charge on the tonnage mined. One mine in particular is obliged to keep an 8-in. discharge pipe running full most of the time, to keep the mine dry enough to be worked.

The pictures illustrating this article were taken in the Beaver mine, about 6 miles southwest of Bay City, and at the Bliss mine, at Swan Creek.

The photograph showing the machine cutting across the face was taken in one of the driest rooms in the district; even so, trouble was experienced in keeping the flash powder dry enough to enable a good picture to be taken. In taking the picture of the machine just ready to sump under the face, the camera tripod had to be placed in about 3 in. of water. This place is about the wettest being worked at this time, and the dripping from the roof causes no little annoyance to the miners and makes the haulage roads hard to keep up.

Undercutting is usually done in the coal itself, as neither the gritty fireclay nor the sandstone bottom which sometimes replaces it, is suitable for mining. A sulphur band near the bottom of the seam gives trouble in some mines, and makes it necessary to cut above the sulphur and lift the bottom coal after the rest of the seam is shot out. In other cases, the machines cut through the sulphur, as will be described later.

In order to make coal mining a paying investment under such conditions, the operator must employ the most economical means possible to win the coal. In early days the coal was undercut by hand pick. Pick machines were introduced in 1898, but have not been extensively adopted. Eighty-five machines, including a few of the chain-breast pattern, were used in 1904, when 23.09 per cent. of the total product was mined by machine. By this time hand-pick cutting had practically disappeared, and the remaining 77 per cent. was won by shooting from the solid, a dangerous practice and a wasteful one, on account of the high proportion of slack coal produced by the heavy powder charges necessary. In the year ending Dec. 1, 1910, 561,688 tons out of a total of 1,473,874 were mined by machines, or 38.1 per cent.

Fig. 2. The Bliss Coal Company's Plant at Swan Creek, Mich.

Continuous Cutters

In the last two years, the situation has been changed materially by the introduction of electric chain machines of the Sullivan continuous-cutter pattern. The chain-breast type was less satisfactory than these, because the machine occupied so much room in front of the coal that props had to be moved and replaced to permit its passage, while the rear jack, forced into the roof at frequent intervals, constituted an added danger from falling top. The bulk and weight of breast machines and the severe labor connected with handling them in such low coal, also proved a serious handicap. The typical advantages of the continuous cutter are of great value in this field.

The Sullivan class "CE6" low-vein machine is the pattern in principal use. More than 80 per cent. of the chain machines now actually at work in this field are of this type and make. This machine stands only 21 in. high when cutting,

and 30 in. high on its power truck. Props can be set less than 6 ft. from the working face, and need not be moved while the machine is cutting. The cut made by these machines is a clean kerf 4½ in. high, and perfectly free, without sprags at the back, while a square working face is left for the next cut. But little powder is needed for shooting, so that not only is the roof left unshaken, but very little coal is wasted in cutting. The proportion of lump coal is much higher than that obtained by any other method.

The Sullivan continuous cutter is shown in operation in the accompanying illustrations, taken in the Beaver mine. The machine in Fig. 4 was unloaded in the room neck, which in this case was at the left side of the room. A jack was set at the end of the right rib nearest the entry, and the machine pulled itself along the floor to this point on its feed chain.

Fig. 3. Machine Leaving Room on Self-propelling Truck

Fig. 4. Sullivan Machine Cutting across the Face

Undercutting the Coal

The rib and the face were then cut in one operation, with no other hand labor than that involved in setting the anchor jack and the takeup rig when the corner was reached, and in shoveling out the coarse cuttings from the cut behind the machine. In the picture the machine is part way across the face. The anchor jack is set to hold the feed chain and the machine with it, a little away from the face, to square it up, as it was being cut by machine for the first time. The mining is 5 ft. 3 in. deep. This particular machine was equipped with feed gears which propelled it along the face on its chain at the rate of 15 in. per minute. The room was mined in less than an hour, including 60 ft. of undercut, unloading, handling, and reloading the machine on its power truck, for transportation to the next working place, as shown in Fig. 3.

Practice regarding cutter bits varies in different mines. In the Sullivan machine, the bits are staggered in five positions or rows. In clean, hard coal, bits with pick points are used altogether. In coal that is clean and soft, the most rapid progress is made with chisel-pointed bits. In both the Beaver and Bliss mines, sulphur occurs near the bottom of the seam in sheets $\frac{1}{32}$ to $\frac{1}{16}$ of an inch thick. A combination of the two styles of bits is used here, the proportion of chisel points increasing when more impurities are met, in order to protect the cutter chain from the file-like cutting of the sulphur sheets.

These machines load themselves on their trucks, unload and propel themselves in all operations on and off the truck, under their own power. This is a very important advantage in the low head room available, where lifting and moving heavy machines is handicapped by the cramped space in which the men must work.

The Beaver Mine

The Beaver mine is operated under the same management as the Robert Gage Coal Company, and is one of the oldest openings in the district. Owing to natural difficulties, such as the sulphur referred to above, and the large amount of water encountered, as well as lack of capital, it has never passed the development stage. The present owners are attacking their problems in a systematic and intelligent manner, and the methods they have adopted promise to overcome the difficulties and place the mine on a paying basis. At present, the Sullivan machines are used almost entirely in development, cutting entries and room necks and widening rooms. When enough working places have been squared up to provide cutting for all five Sullivan machines, the mine will become quite a factor in the production of the district.

The Robert Gage Coal Company and mines under the same management now employ about 20 Sullivan continuous coal cutters.

The surface equipment of the Beaver mine, shown in Fig. 1, is adequate to handle a large tonnage and is uptodate in all respects. It includes a modern steel-plate ventilating fan. The mine is equipped with a steam hoist and a steam-driven electric generator for lights and power. Well appointed machine and blacksmith shops enable equipment to be kept in constant repair. A company store is maintained for the convenience of the employees.

The labor in the Michigan field is of a high class and the men are all members of the union. The basis of payment is $1.01 per ton for all coal shot from the solid which will pass over a ⅞-in. diamond bar screen. The slack which falls through the screen is not credited to the miner. When machines are used, the percentage of slack is smaller and the miner has little dead work to do. The wage scale in machine mines give 59c. per ton of screened coal to the loader, and 19c. to the machine runner and his helper, or a total of 78c., which, deducted from the hand-mining rate, leaves a margin of differential for the operator of 23c. per ton. This is an inducement for machine mining, aside from the greater value realized from the output.

The men are paid off twice a month. Because of the proximity of the mines to towns and cities, the mining camp customary in other fields is generally lacking. The mine buildings stand in flat, rather desolate, fields, aloof from the other signs of civilization. The men live in Bay City, St. Charles or Saginaw, where their families can enjoy schools and other advantages. They go to and from the mines each day by train. Most of the mines in this section run wash rooms for the miners, where the men can leave their pit clothes to dry. An attendant keeps the building clean, sees to drying the clothes, and provides hot water, towels, soap, etc. For these conveniences a charge of 4c. or 5c. per day is made.

I am indebted to the mine officials of the Beaver Coal Company and of the Bliss Coal Company for photographs and for assistance rendered in preparing this article.

Determination of Meridian

By D. J. Browne*

This method permits Polaris observations to be taken at any hour of the night, and offers an easy graphic method of computing the results.

*Mining engineer, Rossland, B. C.
NOTE—From *The Engineering and Mining Journal*, Nov. 11, 1911.

The mine surveyor, in the course of his work, is often called upon to determine meridian, especially when surveying at remote places out of convenient reach of established survey lines. In such a case, unless he is prepared with the data necessary for one of the solar methods—and these need an accurate knowledge of the time and current tables of solar declination, both of which may be difficult to obtain at short notice—the remaining methods at his disposal are limited to two or three, all based on stellar observations. The best known of these are: (1) Method of equal altitudes, and (2) Observation of Polaris, or another star, at elongation. Both methods are satisfactory, and their accuracy is limited only by the care taken and fineness of instrument employed; but either may entail the disagreeable necessity of an all-night session, with the risk of failure, should a cloud intervene at a crucial moment.

This risk is obviated by the following method, in which the position of the pole is determined by two or more observations on Polaris (in northern latitudes). These may be taken at irregular intervals, at the will of the surveyor; a useful feature, if, owing to clouds, the star cannot always be seen. The only data needed are the polar distance of Polaris, and the approximate latitude of the observer. Between latitudes 25 and 50 deg., knowledge of the latitude to the nearest quarter degree is sufficiently accurate for this purpose.

The polar distance of a star is its angular distance, on the celestial sphere, from the pole. The polar distance of Polaris on Jan. 1, 1911, was 1 deg. 10.1 min., and it is lessening by about 19 sec. each year.

Method of Observation

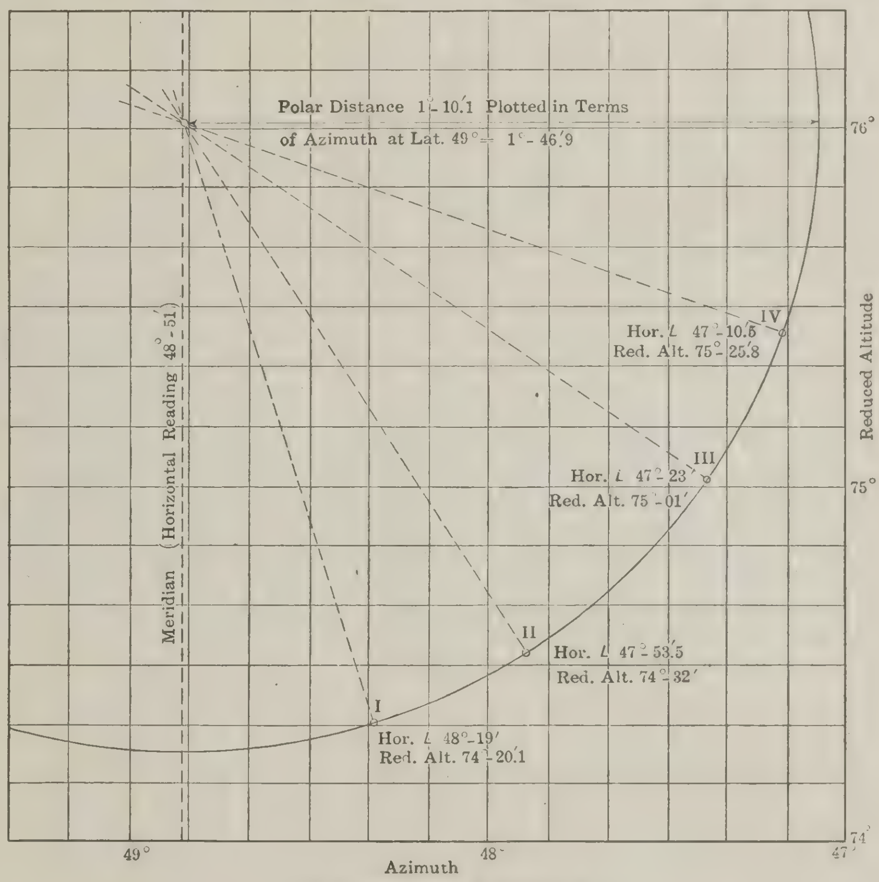
The field operations are as follows: Set up the transit over a hub of a permanent kind in a spot sheltered from the wind, and with an unobstructed view of the northern heavens. Then, with the horizontal vernier clamped at zero, backsight to another station 100 ft. or more away, the position of which should be precisely indicated by an illuminated plumbline centered over it. Set the lower clamp, reverse the telescope and sight Polaris, following the star with both vertical and horizontal tangent screws until it is at the intersection of the cross-wires, so that both altitude and azimuth can be read. Note the time and read both circles. Then, after an interval of one hour or more, make a second observation.

Theoretically, all the data necessary for determining the position of the pole have now been obtained, but in practice it is desirable to make at least two more observations, as a check against errors of manipulation and to eliminate partly any faulty adjustments of the instrument. With the latter object in view, make the first pair of backsights with the telescope direct, and the last pair with it reversed. The main source of error, to be corrected by this means, lies in the horizontal axis of the instrument, particularly in high latitudes where there is a great difference in elevation between backsight and foresight, owing to the greater altitude of the pole.

The object has been to find the position, relative to the survey line, of the circular path in which Polaris appears to move round the pole, and this has been done by fixing two or more points in it. The radius of this circle is the polar distance of the star, and as this distance is an angular one, the problem of finding the center belongs to spherical trigonometry. Polaris, however, is so close to the pole, and consequently involves so small a portion of spherical surface in its apparent orbit, that the methods of plane geometry may be used without introducing appreciable error. The task of reducing the observations, therefore, becomes the simple one of finding the center of a circle, given two points in its circumference, and its radius.

Graphic Solution

This may be easily and quickly done graphically, especially if squared paper be used, by plotting the horizontal components of the points on the circle as abscissas, and the vertical components as ordinates, first reducing the radius, or polar distance of the star at elongation, to terms of azimuth. In explanation of this, it should be pointed out that polar distance is measured in a plane either containing, or parallel to, the earth's axis; and that in consequence, it is not the same angle as the azimuth of the star at elongation, except at the equator. The relation for any latitude is:



Determining the Meridian

Sine azimuth = sine polar distance ÷ cosine latitude.

Hence it follows that the azimuth of a star at elongation is variable with the latitude, and increases as the observer goes north, until a latitude equal to the complement of the polar distance is reached when it would be N. 90 deg. E., or N. 90 deg. W., according as the star is in eastern or western elongation.

Determining Path of Polaris

Now, a little consideration will show that the horizontal and vertical readings

TABLE OF MEAN REFRACTIONS

Computed from barometer 30 in., and temperature 50 deg. F.

Altitude	Refraction		Altitude	Refraction	
Deg.	Min.	Sec.	Deg.	Min.	Sec.
10	5	19	20	2	39
11	4	51	25	2	04
12	4	28	30	1	41
13	4	07	35	1	23
14	3	50	40	1	09
15	3	34	45	0	58
16	3	20	50	0	49
17	3	08	60	0	34
18	2	58	70	0	21
19	2	48	80	0	10

of the transit, if plotted to the same scale, will indicate the apparent path of Polaris, not as a circle, but as an ellipse. This is because the abscissas represent azimuths and not horizontal components, or projections of polar distance, while the ordinates, or altitudes, are true vertical components of polar distance. Therefore, in order to restore the circular form to the orbit, the altitudes must be plotted to a scale greater than that of the azimuths according to the ratio, azimuth at elongation ÷ polar distance. Thus, if a length of 3 in. represents 1 deg. of azimuth, then 1 deg. of altitude should be represented by a length of 3 in. × azimuth ÷ polar distance. When, however, the latter scale is such as to be difficult to adapt to prepared squared paper, plot instead the product, altitude × azimuth at elongation ÷ polar distance (preserving its angular form of degrees and minutes) on the ordinate axis, 1 deg. of this "reduced altitude" being drawn to the same scale as 1 deg. of azimuth. The observations having been plotted in this way, find the center of the circle, or the pole, with dividers or compass set to a radius representing azimuth at elongation.

When working to an error limit of 30 sec., which is all that is usually required of the mine surveyor, it is not necessary to apply the correction for refraction at latitudes higher than 10 deg., as a glance at the following table of mean refractions will show:

As there is little more than 2 deg. difference in altitude between the upper and lower culminations of Polaris, the correction for refraction is, for our purpose, the same for all positions of the star. If, however, the observations have been made with the double object of determining both azimuth and latitude, it is hardly necessary to say that the correction must be applied.

Example of the Process

The following is a practical example of the method:

Latitude of observer, 49 deg. N.

Date, Jan. 1, 1911.

Polar distance of Polaris, 1 deg. 10.1 minute.

The instrument was a 4-in. mine transit, with full vertical circle, both circles reading to minutes and by estimation to half minutes. Four observations were made, at intervals varying from 1 to 1½ hours, first backsighting to a station situated about 100 ft. to the southwest, inverting the telescope, and turning a left deflection angle to Polaris. The first pair of backsights were taken with the telescope direct and the last pair with it reversed. Then, after calculating azimuth at elongation as follows:

REDUCED FIELD NOTES

Observation No.	Time	Horizontal Angle		Observed Altitude		Reduced Altitude (Altitude × azim. at elong.) / polar dist.	
		Deg.	Min.	Deg.	Min.	Deg.	Min.
1	7:10 p.m.	48	19	48	44½	74	20.1
2	8:10 p.m.	47	53½	48	52½	74	32
3	9:40 p.m.	47	23	49	11½	75	01
4	10:40 p.m.	47	10½	49	28	75	25.8

$$Sin.\ azimuth = \frac{sin.\ polar\ distance}{cos.\ latitude.}$$

$$= \frac{sin.\ 1\text{-}deg.\ 10.1\ min.}{cos.\ 49\ deg.} = sin.\ 1\ deg.\ 46.9\ min.$$

$$Log.\ sin.\ 1\ deg.\ 10.1\ min. = 8.309410$$

$$Log.\ cos.\ 49\ deg. = 9.816943$$

$$Log.\ sin.\ 1\ deg.\ 46.9\ min. = 8.492467$$

the vertical reading at each observation was reduced to the form necessary for plotting, as shown below:

The third and fifth columns were plotted on squared paper as abscissas and ordinates, respectively, with the result seen in the accompanying diagram, the scale being 1 in. to 20 min. Then, with compass set to a radius representing 1 deg. 46.9 min., the position of the pole was found by the intersection of arcs drawn with centers at each plotted point in turn. Its azimuth reading was angle, left 48 deg. 51 min.; hence the bearing of the survey line from back station to instrument was N. 48 deg. 51 min. East.

World's Production of Coal

The total coal production of the world in 1910 was approximately 1,300,000,000 short tons, of which the United States contributed about 39 per cent. This country has far outstripped all others, and in 1910, according to the United States Geological Survey, it exceeded Great Britain, which ranks second, by over 200,000,000 tons. Great Britain's production in 1910 was less than 60 per cent. of that of the United States, and Germany's was less than half. The increase in both of these countries in 1910 over 1909 was comparatively small, whereas the increase in the United States was nearly equal to the entire production of France and was more than the total production of any foreign country except Great Britain, Germany, Austria-Hungary and France.

The United States has held first place among the coal-producing countries of the world since 1899, when it surpassed Great Britain. In the 11 years since 1899 the annual output of the United States has nearly doubled, from 253,741,192 short tons to 501,596,378 tons, whereas that of Great Britain has increased only 20 per cent.

The following table shows the coal production of the principal countries of the world in 1910, except those for which only the 1909 figures are available.

THE WORLD'S PRODUCTION OF COAL, IN SHORT TONS

United States (1910)	501,596,378
Great Britain (1910)	296,007,699
Germany (1910)	245,043,120
Austria-Hungary (1909)	54,573,788
France (1910)	42,516,232
Belgium (1910)	26,374,986
Russia and Finland (1910)	24,967,095
Japan (1909)	16,505,418
Canada (1910)	12,796,512
China (1909)	13,227,600
India (1909)	13,294,528
New South Wales (1909)	7,862,264
Spain (1909)	4,546,713
Transvaal (1910)	4,446,477
Natal (1910)	2,572,012
New Zealand (1909)	2,140,597
Mexico (1909)	1,432,990
Holland (1909)	1,235,515
Queensland and Victoria	1,119,708
Italy (1909)	611,857
Sweden (1909)	272,056
Cape Colony (1909)	103,519
Tasmania (1909)	93,845
Other countries	5,236,903
Total	1,278,577,812
Percentage of the United States	39.2

Fans at Bruceton

The following is an official statement of the sizes of the fans installed and to be installed at Bruceton mines. The one which was in use at the time of the explosion was a Sirocco, 3 ft. 6 in. in diameter by 21 in. wide and had a nominal capacity of 12,000 cu.ft. against a 1-in. water gage.

The larger Jeffrey fan to be installed is 8 ft. in diameter, and 2 ft. 6 in. wide and has a capacity of 80,000 cu.ft. of air against a 2-in. water gage or 20,000 cu.ft. against a 6-in. water gage.

Coal Gas Explosion, Vivian, W. Va.

Editorial Correspondence

> *This explosion might have been recorded among the most destructive mine disasters had not the mine been kept damp by humidification of intake.*

The Bottom Creek Coal and Coke Company's Mine No. 1, at Vivian, W. Va., was the scene of an explosion at 11 a.m., Saturday, Nov. 18, in which eighteen men were killed and three injured. There is no question as to the real cause of the explosion; a body of gas collected in the face of Room 7 in 11th Left and was ignited by an open lamp carried by one of the members of an engineer corps. These men were engaged in surveying the new work in the mine on behalf of the Crozer Land Association, the lessor of the property.

The Bottom Creek Mine No. 1

The Bottom Creek mine is situated on the right bank of the Elkhorn creek at a point where Bottom creek enters the larger stream. The Elkhorn has made a narrow valley, not over 600 ft. wide for the most part, with hills about 600 ft. high on either side. The Indian ridge, which is the northern watershed of the Tug river and of its branch, the Elkhorn, lies nowhere more than four miles distant. The Tug branch lies about as far to the south, so that there is but little water received by the Elkhorn on either bank, and consequently, as a stream, it is of little importance. However, as the Pocahontas bed known as No. 3 crops out conveniently nearly all along the stream from its headwaters in the Blue Stone ridge, the economic importance of the valley is immense and plants follow one another along the narrow waterway in a manner almost continuous. The coal dips toward Welch, the capital of McDowell county, and at that town it is below water level. At Vivian, however, the coal is still 40 ft. above the water level of the Elkhorn. Being about to be submerged below water level, the coal at Vivian has more gas than at points further up the valley. The plant is situated, like all others in McDowell county, on the Norfolk & Western Railway at Vivian, which lies about six miles east of Welch and 28 miles west of Bluefield.

Gas in Virgin Coal

The main entry is nearly on the strike and consequently the point at which the explosion took place is above the water level of the Elkhorn. But, as stated, probably owing to the submerged condition of the coal to the west, the measure emits firedamp, and firebosses have been employed for over fifteen years. The mine is worked without the use of safety lamps, as are all the mines in this district.

It has been customary also to employ entry bosses at each section of the mine, some bosses having one and some two entries in charge. The duties of the entry boss are to superintend the work and unless some company men happen to be absent, the entry boss is not required or expected to perform any other duties. The entry boss has a safety lamp and he is supposed to aid in watching for the presence of firedamp.

The Workings of the 11th Left

It must be remembered that here, as in many of the newer fields, the principles of conservation are being diligently followed by all the coal operators, though by some more than others. Many mines are in a transition stage from an advancing room-and-pillar system by panels to a retreating system of like kind. The Bottom Creek Coal Company is changing its method, but the headings are not advanced as much as is needed for that purpose. The mine inspectors are urging upon the operators a course of action in heading driving which is not required by the law, but which makes for safety in gaseous mines. This safety provision, which will be described later, is being observed at Bottom Creek. It has delayed heading driving and the the change from advance working to retreating is proportionately slow. Consequently the new working scheme, though adopted in principle, is temporarily not being put fully into practice.

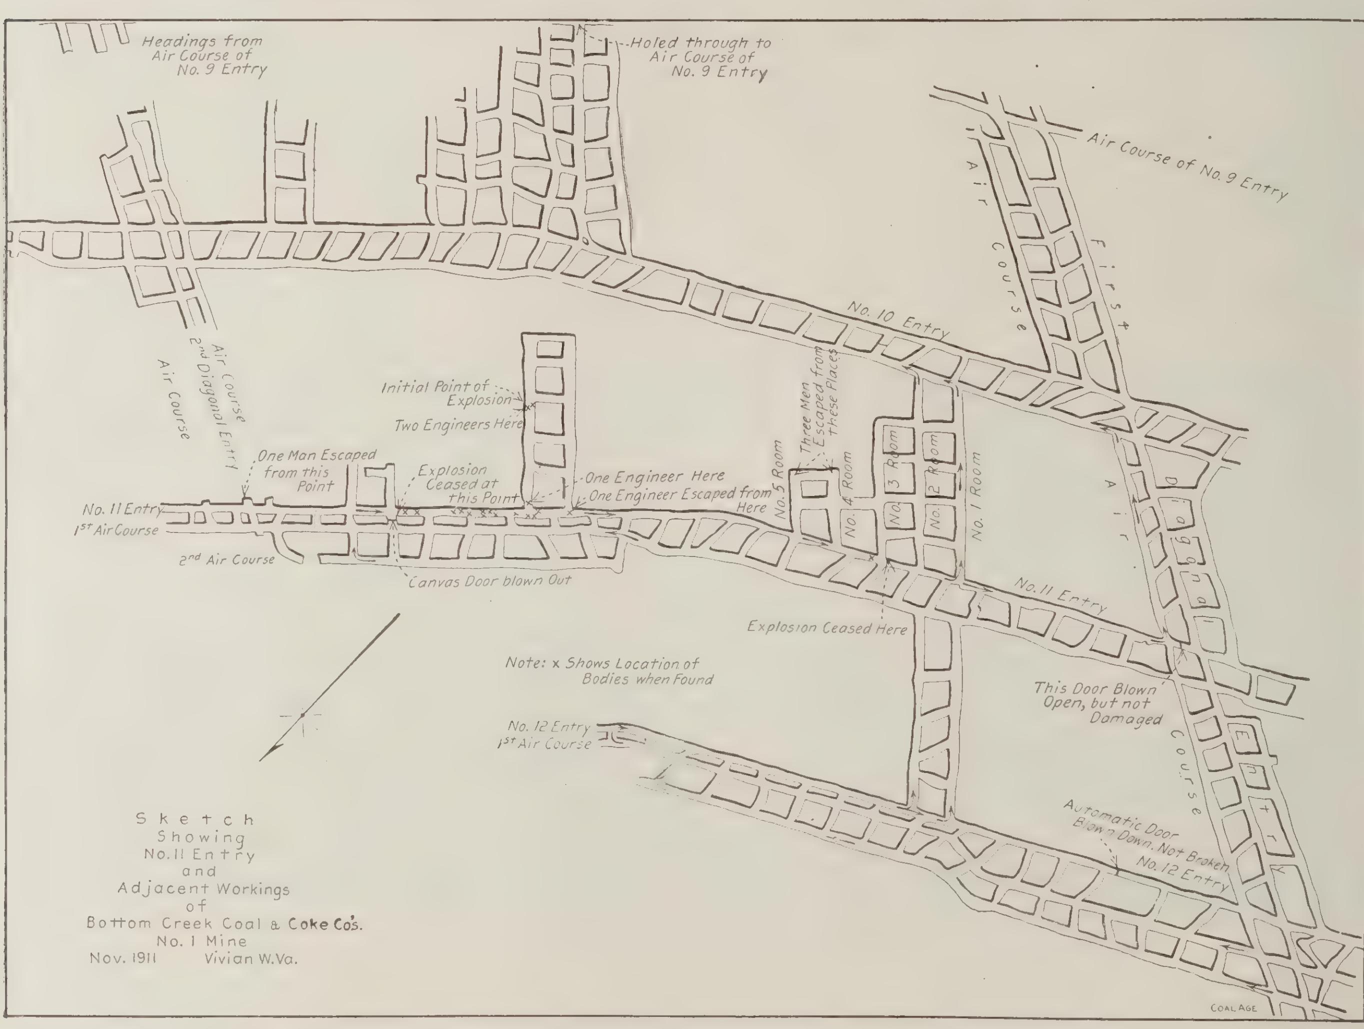
An occasional pair of rooms is driven up so as to provide the coal needed to maintain the output. This will account for the irregular appearance of the workings in 11th Left, the rooms numbered from 1 to 9 being driven in irregular sequence, and leaving places for others yet to be started in between them. On Nov. 18, rooms 4 and 5, 8 and 9 were still working and acting in pairs as airways to each other, but the other five rooms were idle, having been extended as far as was necessary. The track was drawn out of them, but they were standing in good condition, the intention being to draw the pillars when rooms inbye from them were finished and their pillars were being drawn back.

Tipple of Bottom Creek Mine No. 1, Vivian, W. Va.

The Chain Pillars

Perhaps a digression may be made here to explain the reason for the inequality of the two chain pillars at the end of the heading. The inspectors do not favor the driving of headings, where there is any firedamp present, over 80 ft. beyond the last crosscut. At this distance the West Virginia mining law requires a crosscut to be driven between the headings and the inspectors recommend that no further progress be made in advancing the pioneer work until the crosscut is completed. When the pillar between the haulway and airway was maintained at a thickness of 40 ft., the driving of this crosscut took so long that the advance of the headings was seriously impeded. For this reason the pillar is cut down to 20 ft. It will be seen how much narrower the right-hand chain pillars are in the recent work than they formerly were. The second airway, as it is termed on the plan, is driven up to reduce the velocity of the air and the consequent friction. This airway is allowed to lag a little behind the other two and the crosscut between it and the first airway is driven ahead of the lagging aircourse. Sections of heading, as can be seen in the case of the 11th entry, are often driven from the ends of the crosscuts back to meet the face of the advancing airway.

The coal measures 5 ft. 9 in., the immediate roof consisting of from 9 in. to 2 ft. of loose gray slates or shales, which are here extremely friable and which change their condition and fall when exposed to the air. Above this is a black slate, 1 ft. to 2 ft. thick. This slate breaks off in many cases close to the point of support. Above this the roof consists of hard, thick, gray slates on which reliance can be placed.



Plan of Three Entries in Bottom Creek Mine, Where Explosion Occurred

Engineers of Crozer Land Association

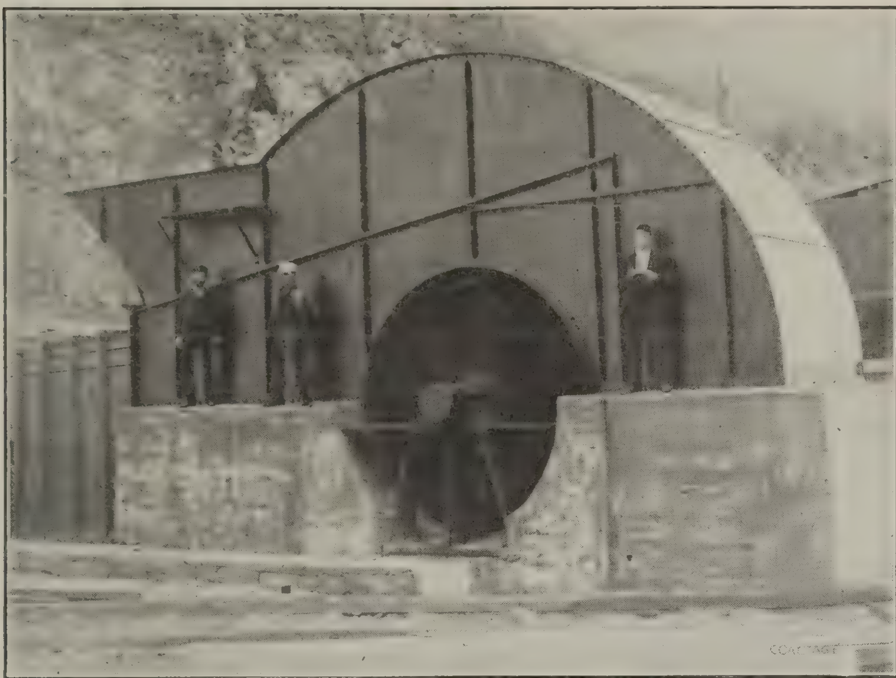
The Bottom Creek concern leases its coal from the Crozer Land Association. The mining companies in McDowell county for the most part lease either from the Pocahontas Coal and Coke Company, or from the association just mentioned. Close check is kept to see how much is extracted and what proportion it bears to the whole content of the field mined. On Saturday, the surveying corps of the association, with W. H. Henderson in charge, entered the mine to make surveys preparatory to posting up the maps. They passed the fireboss on the road in but did not speak to him, nor he to them. It is said that they did not see the entry boss in charge of the heading. It has been the custom for the engineer of the Bottom Creek Coal Company to notify the entry boss before entering any abandoned place, and to keep out of that place till it had been examined by him. This was not done in this case, the corps evidently feeling assured that there would be no risk in entering any of the abandoned rooms. Two men went into room 7 to measure it up, and had probably reached a point opposite the third crosscut, 240 ft. from the haulway when the firedamp was ignited. This point is 160 ft. from the face of the twin rooms. The men were found lying at that point, when the search was made. Two others of the party were at or about the entry to this room. A helper was at the entry to room 6. He saw the flare coming down that room and fell down on his face or was knocked down. His story varies. The time must have been very short and it is probable that this act was not so much voluntary as the outcome of force. His hands were spread out before him and the passing blaze burned them severely. While unable to walk, he crawled some

hundred feet to a place lower down, where he was found by a rescue party and removed to the hospital. He is doing well and is expected to show few signs of his terrible experience. That he was not asphyxiated may have been due to a short circuiting of the air current as a result of the explosion. The four other members of the party were instantaneously killed by the violence of the expanding gases.

Thirteen Unnecessary Fatalities

The explosive violence proceeded in both directions from the mouths of rooms 6 and 7, and in traveling toward the first diagonal heading shown in the right-hand side of the plan, it killed one driver and two mules. It passed two drivers, each driving two mules in a team. One mule was killed and one saved in each team. The plan accompanying this article is that furnished the mine inspectors for filing with their report. A note shows where the explosion ceased, but from information from the company it is clear that the concussion traveled somewhat further, but its main evidences were confined between the limits indicated.

In view of the fact that almost everyone would have done what the men did who were back of the explosion in the 11th Left, it seems an unfair judgment to pass to say that through fear or mistaken reasoning they ran to a common and fearful death. But it is unfortunately true, and it is to be hoped that the statement may have some value as a warning. The shock must have been mild where they were working, as their pails were found full of water. The men rushed down the heading, which was a return airway, and all but one perished from after-damp or rock-falls between rooms 7 and 8, which are about 300 ft. apart. Piles of fallen rock were found over and under their recumbent bodies. Some may have been killed by rock-falls, but possibly all died from suffocation or monoxide poisoning and were covered by rock afterward. It is impossible to assert with confidence the actual cause of death, except that they were not killed by the force of the explosion, nor were they burned by the flame. Among them were two company men, four slatemen and seven miners. One man working in the diagonal airway placed his cap over his mouth and got out, passing all the others. It is to be regretted that the men with one accord ran down the haulway by which the air returned instead of taking the intake airways, one at least of which contained only pure air.



16-ft. Fan, Which Delivers Air to Bottom Creek No. 1

A Firedamp Explosion

The Pocahontas coal dust has a bad quality of aiding explosions, making it possible for comparatively small accumulations of gas once ignited to cause severe dust explosions. That a severe catastrophe, involving all the 150 persons in the Bottom Creek mine, did not result from the puff of flame which directly killed only five men, was because the mine was kept thoroughly wet by humidifying the air with exhaust steam from the fan engines. This fan, shown in the illustration, is 16 ft. in diameter. At the time of the explosion it was making 120 r.p.m., and the full exhaust passed by an 8-in. line into the workings. To show the effect of this discharge of steam on the exposed surfaces in the mine, it may be stated that canvases erected by the rescue parties are wetted through already by the damp air passing through the mine. Only a few mines in this region humidify the air with steam and the fact that this explosion did not extend beyond narrow limits will tend to make the practice more common. Beside humidification by steam, the coal dust is watered by tanks at this mine and in others, but the main reliance at Bottom Creek is placed in the use of the exhaust from the fan engines. The system has not been very long in force, but it is most favorably viewed by the management. Mr. Samuel W. Patterson, the general manager of the mines and vice-president of the company, says it has not affected the

Village of Vivian, W. Va.

roof and ascribes the localization of the explosion to the use of steam on the intake.

The Mechanical Effects

The explosion blew down some of the stoppings near the center of detonation. They were built of stone, but were not as strong as such stoppings often are, the cementing of one face rather than the thickness of the wall being depended upon to preclude the passage of air between the headings. Strong stoppings increase the violence of explosions by giving them no chance to spread sideways and are not generally favored. However, where dry dust can be found everywhere the extension of an explosion in all directions merely increases its severity. In this case the breaking down of the stoppings probably reduced the violence of the explosion and gave it no additional fuel on which to feed. At the same time it short-circuited the air, assisting all men outbye of the explosion but leaving the foul air undiluted to the inbye.

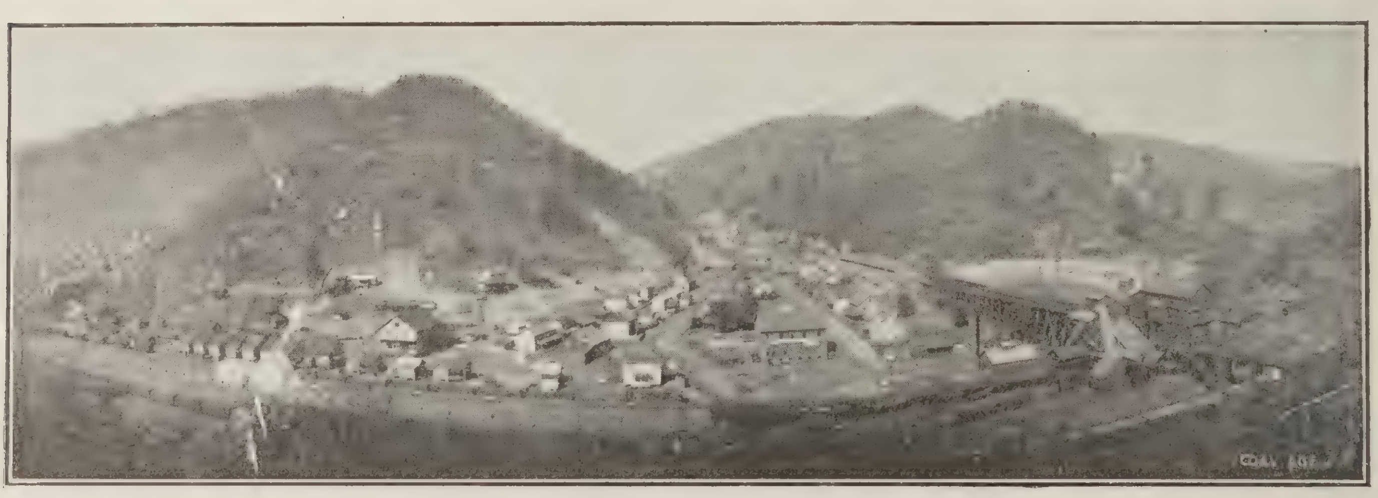
The concussion extended to the 12th left and blew an automatic door in that entry out of the perpendicular, thus short-circuiting the air current to the 11th left. Otherwise there was no damage done and the men in other headings had to be notified to leave, as they did not realize that anything had happened. They made their way out without difficulty.

The Rescue Work

The rescue was easily effected by the mine officials. The foreman pushed back the door in the 12th left, which was in no way injured, thus reëstablishing the air in the 11th left. The rescue party proceeded by the return as far as possible and then completed the work from the intake end. The men in other parts of the mine were meanwhile hunted up and told to leave the mine. Of the men killed four were white Americans, five were colored, three were Hungarians and three Russians. The three others were Slavonian, Lithuanian and Italian, respectively.

The testimony given before the coroner's jury showed that the rooms in which the explosion took place had been examined within a week and found to be free of gas. It was also stated that a danger board had been placed at the mouths of those rooms, but, of course, the explosion rendered a statement of that kind not subject to verification. When the mine foreman, two days before, measured the air in the last crosscut of the split, he found 15,000 cu.ft. per minute circulating through it. This split, it may be added, carried the air which ventilated the 10th, 11th and 12th entries.

The coroner's jury found that the men came to their death by an explosion of gas in an abandoned room, No. 7, in No. 11 entry of the Bottom Creek Coal and Coke Company's mine at Vivian, McDowell county, W. Va., on Nov. 18, 1911, at about 11 o'clock a.m., and further, that said gas was ignited by an open lamp carried by some member of an engineering corps then working in room No. 7 of entry No. 11 of said mine.



Bottom Creek Coal and Coke Company's Tipple, Coke Ovens and Houses

Estimating Gas Percentages

A novel method of determining the approximate gas percentages with the ordinary safety lamp, and without the use of any special appliances, has recently been described by an English engineer. It frequently happens when in the mine and away from special appliances, that it is desirable to know roughly the approximate percentage of gas in a certain place, and the following method is recommended for use in such contingencies.

Having made preliminary examination to insure that gas is not present in dangerous quantities, the flame of the safety lamp is lowered until only a mere speck of white light remains at the tip. The eye, being accustomed to the brighter light, will require a few seconds before the cap can again be distinguished. When, however, the outline of the cap is again fully discernible, the flame is slowly and carefully raised. It will be noticed that the size of the cap will increase with the size of the flame, but in the brighter light of the latter, the former will eventually disappear. The point at which the cap becomes invisible determines the percentage of gas, as of course the larger the percentage, the less quickly will the cap disappear.

The fireboss to be able to handle this adequately must, of course, have the opportunity of experimenting in known percentages of gas. In these experiments he will find that with 3 per cent. gas, the cap disappears when the flame has reached a certain hight, while for 4 per cent. the flame is somewhat higher, and so on.

This method should not be construed as an accurate determination, nor is it one that may be used in the presence of large quantities or dangerous proportions of firedamp with safety. It is believed, however, that there are many occasions at the working face when it will be found applicable.

Mining Laws in the State of Washington

Special Correspondence

The Senate bill No. 112, Chapter No. 123, Laws of the 1911 session of the State of Washington provided for the appointment of a commission to revise the State coal-mining inspection laws. The revised and recodified laws of this State, as provided by this commission, will be printed in the form of a Legislative Bill to be presented to the members of the Legislature of 1913 on or before Dec. 1, 1912. Two thousand dollars have been appropriated by the Legislature for the purpose of paying the necessary expenses of the commission. Up to the present there has been no examination provided for superintendents, foremen, shotfirers, or firebosses in this State.

Issued Weekly by the
Hill Publishing Company
John A. Hill, Pres. and Treas. Rob't McKean, Sec'y.
505 Pearl St., New York.
6 Bouverie St., London, E. C.
Unter den Linden 71, Berlin.

Correspondence suitable for the columns of Coal Age solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, *we will print 7000 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.*

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

Contents

COAL AGE

Humidification

There has been a great deal written about the deleterious effects of humidification. It has been asserted that dampness is harmful to the health, endurance and comfort of the men who are subject to its depressing influence. It has even been hinted that specific germs may have been fostered by it. Moreover, it has been said that constant deterioration takes place in the roof, as a result of its adoption, making dangers from falls of rock greater and costs of mine maintenance excessive.

It were well not to argue the point which may in many cases have a reasonable basis. Rather, it would be better for each operator or superintendent to determine for himself the value of the arguments against humidification. To assume results of any line of action when an experiment would definitely determine the problem, is not so practical as it is popular. In cases where a blowing fan is being used and the exhaust can be readily turned into the intake, the experiment will involve no appreciable cost and is well worthy of a fair trial.

The experience at Vivian, W. Va., forcibly exhibits why the experiment should be made. A forceful gas explosion occurred in a mine having well dampened but highly explosive dust spread through its workings. Yet the explosion died out speedily and, as an explosion, pure and simple, it is probable that it did not pass much beyond the two rooms in which it initiated. Expulsions of burned gas undoubtedly traveled further. The concussion, of course, exhibited itself over a still larger area. But even this was evidenced over a space not exceeding 75 acres. The shock did not create a dust-laden atmosphere of the kind or degree on which the flame might feed and the explosion extend. Here then the principle of humidification was conclusively vindicated.

While some dusts, notably those from the coals of the Allegheny series, are fairly inert, it is not safe to assume that any dry dust is harmless under all circumstances. The Adrian explosion appears to have originated from, and to have been propagated by, dust. Yet Adrian slope was a Lower Freeport operation, and the dusts of the Freeport coals are considered relatively inactive. It is a new rôle they fill, when they initiate such a disaster as that at Adrian. Consequently, it is not out of reason to urge that even the more inert dusts of bituminous coal cannot be declared off-hand to be safe.

In cases, therefore, where moistening the air of the mine costs nothing, hurts nobody and destroys nothing, is it necessary that the practice be proved essential for safety in operation in any particular case where its adoption is urged? It seems that the burden of proof should fall on other shoulders. Each operator should prove conclusively that humidification is either not needed, or is harmful or excessively costly in operation. The anthracite operators alone may be able to claim immunity on the first count. Where it is costly and abundantly proved unnecessary, then it might be prudent not to urge it; but where it is cheap and harmless, the argument that it is not proved necessary should not have any weight whatever.

It is for these reasons that the extension of the practice is to be looked for in regions where it has been hitherto known only to the student of mining.

Storing Coal

The storage of large quantities of coal has become an important phase of the anthracite industry. The necessity for such storage was first recognized a number of years ago in connection with supplying the Western markets while navigation was closed on the Great Lakes. As its efficacy to meet the requirements arising from other conditions has been realized and proved, the storage system has been gradually extended throughout the mining region and along the lines of the principal hard-coal railroads, until now all the larger anthracite coal and railroad companies own and operate plants ranging from several hundred thousand to upward of a million tons capacity.

Ordinarily, these plants serve as a sort of industrial flywheel to absorb shocks coming from sharp alterations in the conditions of supply and demand, but their chief reason for being, is found in the labor troubles which periodically threaten the industry and occasionally mature.

From all recent indications, the anthracite operators have been acting on the principle that one way to avert trouble is to be prepared for it, and during the past season have been filling their storage depots to the limit of their capacity. This measure is not threatening or particularly significant; it is the usual and expected action at a time like this when the agreement with the mine workers is about to expire, but in the event of a strike, this accumulated supply of coal is, up to a certain point, the most potent factor in the situation. By it the strength of the operators' position can be pretty accurately gaged.

The system of storing coal against the emergency of a possible strike operates fairly for everyone concerned, and tends to minimize the evil effects of a prolonged disturbance in the industry. The operators, by producing in nine months what they would ordinarily produce in a year, find the effect of three months' idleness to be practically offset, and the increased efficiency of production under full-time conditions, together with advances in price as the available supply diminishes, probably compensate for the additional cost of storage. This stored coal would also have an enormous speculative value during a protracted strike, but it is the policy of the larger companies not to advance their prices and to use the supply chiefly for protecting their markets against inroads from competitive fields.

The miner, no less than the operator, profits by the increased activity of the months preceding the strike and draws his usual annual earnings in the shorter time. If he is prudent and wise, he will accumulate a surplus to tide him over the period of idleness. However this may work out in the case of individuals, the community in general is the better prepared for an industrial depression.

Of course, the necessary result of so much preparation is to compel a period of suspension, strike or no strike, at the expiration of the agreement, in order that the surplus coal may be used and the industry given time to settle back into its normal state.

Present Day Coal Situation

Some timely and pertinent remarks were made on the present state of the coal trade in this country, by the members attending the last Mining Congress, at Chicago, October 23 to 28, 1911.

When these remarks and suggestions are carefully considered, boiled down and allowed to cool they seem to point the growing urgency of the situation. None of the speakers who took part in the discussion could be said to be so organized that his conclusions and suggestions for remedy would meet with general acceptance. It is a large question entailing, in its final solution, much, as yet, of unwritten law.

One of the most forceful utterances made was that of Walter S. Bogle, Illinois, who said, in the course of his remarks, "The problem or work before us appears to be a campaign of education. . . . It may seem a great undertaking; but the time for it is ripe. The entire business of the country is largely paralyzed by the uncertainty of how that law (Sherman anti-trust law) is going to be applied. The Supreme Court of the United States has said that a *reasonable* combination is right; but the meaning of the word "reasonable" would vary with each individual, and the construction put upon it would be governed by personal interest. . . . . Wherever they (the American people) have become educated to understand any great question of the day their decisions have invariably been right."

Referring again to the operation of the Sherman law, the same speaker said, "The object of the law was good. . . . Every self-respecting business man and citizen of this country will stand for a law that will accomplish that (restrain unjust combination in trade)." Mr. Bogle went on to show that, in many industries, the operations of the law had compelled individuals to "a choice between bankruptcy and the violation of the law" and they have not hesitated to choose the latter and risk the consequences.

Self-preservation is, without qualification, the first consideration—the God-given, inalianable right of the individual. No law is complete or successfully operative that compels its own violation or the degradation of the citizen whose purpose it is to safeguard and protect. In the administration and interpretation of all law, both the government and the judicial courts regard this principle. It is agreed that few laws are so perfect as to require no modification, in administration.

It was stated, in support of this argument, that, notwithstanding it has been declared a violation of law by the Supreme Court of the United States, the Interstate Commerce Commission, with the clearly evident approval of the people of the States, has permitted railroads doing business in several States, to combine to establish and maintain regular and agreed passenger and freight rates.

The same consideration, it was suggested, may be necessary in an equitable solution of the coal-trade problem. The problem is far from being a simple one. (1) The questions relating to the production of coal concern both the physical and industrial conditions affecting the mining, preparation and loading of the coal. The geological character and formation of coal seams, the rules and customs of labor organizations, in many instances, increase the cost of production. (2) The transportation of the coal from the mine to the market is likewise beset with difficulties relating to obtaining cars, freight rates, switching charges and other items that favor one mine above another. (3) Competing markets often lower the price of coal till only those mines that enjoy the most favorable conditions are able to continue to run. Likewise the railroads and some other large consumers of coal demand and obtain prices, on contract, that are ruinous, and would, in many instances, result in running the mine at a loss were it not for the general trade, which must pay a price sufficiently high to cover the deficit that would otherwise occur.

H. N. Taylor, in remarking upon this condition, stated, "If the railroads would pay just a trifle more it would not then be necessary to force the sale price of a comparatively small portion of coal to an extraordinary figure.

Mr. Taylor drew attention to the important effect produced by the filling of large orders for a certain size of coal. For example, to furnish 1000 tons of, say 3-in. egg or nut coal, it is necessary, under conditions existing in many States, to produce perhaps twice this quantity of coal of sizes for which there is little demand and which must be "dumped on the market" at a price below cost of production for such coal.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

Anthracite, the principal household coal in America, is little used in Great Britain except for malting purposes, barley drying, hop drying, heating greenhouses, lime burning, suction and power gas production and on a small scale in steel work.

The habit of using both black powder and dynamite in the same hole is dangerous in the extreme and should be absolutely prohibited. If the dynamite is placed last in the hole, it is apt to blow out the stemming. If placed first, it may blow the slower explosive into the dust raised by the shot.

When working friable coal, the first thought of the miner should be to adopt such a method of mining as will produce the least percentage of small coal. In this respect longwall mining excels all other systems, as the coal is worked in one continuous face, thus necessitating far less cutting, which always increases the small sizes in friable coal.

A continental method for preventing breakage when discharging coal into bins, consists in keeping the bins full of water. The coal is dumped into this water and sinks gradually with little breakage; the water meanwhile overflowing through outlets provided for that purpose. When the bin is full, the water is allowed to drain away and the dried coal is then ready for use.

The practice of tamping a shot with coal dust greatly increases the danger of explosions. Even if wet, the dust is still inflammable; experiments have shown that wet coal-dust stemming gives a flame only slightly shorter than that of dry. Two and five-tenths pounds of black powder and 2.6 lb of dry coal-dust stemming gave a flame 64 ft. long. When the stemming was wet the flame was 50 ft. long.

Tests made at the Pittsburg laboratory, U. S. Bureau of Mines, show that briquets made without binder, from the inferior lignites of Texas, North Dakota and California, give a hot fire with little shaking or poking and burn readily until consumed, with a loss through the grate of only 6 to 8 per cent. of unburned fuel. When burning they give off a small amount of light yellow smoke.

Electric feed wires should be disconnected from the machines when they are being loaded or unloaded, unless the power is necessary for such operations, and all haulage should be suspended where a feed wire is extended for the purpose of fitting a machine. Feed wires should at all times be kept clear of the rails and traffic except when connected, and if they are to be carried across trackage, they should be carried under rather than over the tracks.

Most careful attention should be given to the installation of a pumping plant in a newly opened mine. It should not be designed wholly for the immediate needs, but should be so planned that it will be able to handle the increase of water sure to follow further development of the property. Concentration is the keynote of successful pumping. A central pumping plant, with large capacity pumps, should be the aim of all who desire a well planned drainage system.

Some salient points of economical mine management are as follows: All workings should be concentrated as much as possible. Cutting machines should be kept constantly at work, developing new territory. All main partings should be as near the working faces as possible. Long animal haulages should be avoided and the underground roads receive as much attention as surface roads. Care should be taken that little timber is abandoned in old workings and headings.

In order to attain the highest efficiency in steam production, the coal burned should be spread on in thin layers and small quantities, always taking care to keep the fire level by filling up all hollows. Some prefer depositing the fresh fuel on the dead plate in front of the fire bars and gradually pushing the fire back over the bars as fresh fuel is added. Large quantities of coal should never be shoveled onto a fire at long and irregular intervals. From 6 to 9 in. is a good thickness of fire.

The Arthur D. Little laboratory, of Boston, has designed a coal auger for testing the internal heat of coal storage piles. It is capable of being put down 20 ft. in 5 min. Four-foot adjustable extensions allow it to reach any depth desired. A small maximum thermometer inserted near the point gives the temperature, in about 10 minutes' time, much more accurately than it can be obtained by the old method of a thermometer hung in a pipe, cooled more or less by the circulation of air.

Steel cars have these advantages: they are stronger and hold more coal for the same outside dimensions, while for large loads they are lighter than those of wood and not so easily damaged. When knocked out of shape, however, they are more difficult to get along narrow roads and into cages. As they are constructed of few pieces and without many joints, they do not litter the roads with coal as do wooden cars. They are less suitable for wet mines, because of the effect of acid mine water on metal.

Belgium has 42 factories for the manufacture of square briquets and egg-shaped boulets, which give employment to 610 men. France has 35 briquet-manufacturing plants. England has about 20 plants devoted to briquetting. Spain, China and Japan are also producers of briquets. Compared with other countries the United States is a small producer. At one time 19 plants were in operation, but most of them closed because of inexperience in the methods of manufacture, lack of proper machinery and insufficient knowledge of the use of binders.

At many European plants the coal dust which accumulates in the screening houses is collected for use in the manufacture of facing for iron molders and also of arc-lamp carbons. The dust is collected by means of an exhaust fan, which draws the dusty air through pipes, from underneath hoods built over the shakers or screening tables, into large receptacles where the dust settles and is there loaded into sacks. At a Midland, England, colliery, 2500 lb. of dust per day are removed and sold at a good price. Bituminous- or steam-coal dust is mixed with washed coal for coke making.

In a recent paper before the Institution of Mining Engineers, Mine Inspectors Pickering and Poole remarked that a dread of overwinding accidents is ingrained in miners and managers alike. The reasons are that, when a miner is being raised or lowered, he realizes that he has no control over his own fate. He is dependent upon the skill and attention of others and on the efficiency of the winding appliances. Besides, the fear of falling from a hight is a primary instinct of every heavy animal which walks the face of the earth. The manager knows that, in addition to his responsibility for the safety of persons under his charge, he may be held responsible for serious damage which may stop the pit for some time in the event of a shaft accident.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Mine Checking System

A Good Suggestion

The fact that miners occasionally lose their way in the mine and wander into abandoned workings and become lost therein, emphasizes the importance of having some efficient and generally recognized system of checking both the number and the name of every person who enters the mine. A check office may be situated near the mouth of the mine or at the shaft or slope bottom, and each person passing into the mine should receive a check bearing the number by which he is registered on the books of the company and by which he may be identified in case of loss or accident. At the close of the day when leaving work, or if the person leaves the mine temporarily to return shortly, he should be required to deposit his check in the check room or office, so that it may be known how many men are in the mine at any time, and who they are.

The General Plan of Registry

The arrangement can be made very simple and effective. The labor and expense entailed are not material, compared with the advantage to be derived from the adoption of such a system. First, there is required a mine register that would show the number and name of every man in the employ of the company who would, at any time, have business that would call him into the mine. Such register should also show the name and address of some relative, friend, guardian or other party who should be notified in case of serious accident. All other persons who may, from time to time, enter the mine as visitors, should be provided with a special pass filled out on a blank form printed for the purpose. This pass should be numbered at the check office and the visitor given, in exchange, a brass visitor's check bearing the same number as the pass, which is left at the office while the party is in the mine. The pass, like the mine register, should give the name and address of the visitor and of the party to be notified in case of accident. The pass should, further, over the signature of the visitor, absolve the company from any liability for accident or injury that may be incurred while in or about the mine. This is more necessary with present mine equipment than ever before, because all mine employees are specially warned in regard to the dangers surrounding their work, but visitors to a mine, while receiving the courtesy and attention of a guide, are not familiar with the dangers to which they expose themselves and should naturally assume all risks incident to their visit. The company, in this case, is *host* and not *servant,* in the eyes of the law.

A Card-index Mine Register

Owing to the fact that the list of mine employees is constantly changing, men going away and newcomers taking their places; and, furthermore, because it is desirable that the list of numbers should be continuous and show no voids, but should total the exact number of employees to date, as shown by the highest check number, it is necessary to adopt some system of registering that will admit of change readily.

This could not be effected by any bookroll, but is very simply accomplished by keeping a card index. Each card bears the name, address, age and nationality of the employee, and the name and address of the party he desires should be notified in case of serious accident. Each card, at its time of issue, is numbered, in succession, following the last number of the index, and the party is handed a brass check bearing a stamped number corresponding to the number that is written on his card.

The check is necessary for entering the mine—the same rule applying to every individual employee, from the president down to the door boy. It should be as unchangeable as the old law of the Medes and Persians, which could not be altered. Before entering the mine the check must be deposited in a box and, later, hung on its proper peg, according to its number, where it can be quickly found when the party again comes to the surface.

When a party quits the company he must relinquish his check when drawing his last pay. In order to leave no voids, this check is at once given, in exchange, to the last man on the list; and this man's card is moved up in the index file, and, at the same time, marked with the new number and date of transfer. Not more than one transfer would often occur on a single name, in a long time.

In the absence of a reliable "checking" system, who can say definitely what men are in the mine or out of it? The hysterical, weeping, wailing and screaming of women, who fear that they have been made widows, or have lost fathers, brothers or sweethearts, add to the confusion, which would be greatly reduced by having the exact information that would be afforded by a reliable check board. Aside from this, it is surely "good business" to know, even under "contract working," who are in the mine each day.

Mine Superintendent.

Bolton, England.

German Selling Syndicate

As bearing on the operation of the German selling syndicate, the following criticism from the standpoint of the British Consulate is enlightening.

In a report covering 1910 and the first four months of 1911, Consul-General Sir Francis Opheimer directs attention to the remarkable increase of coal imported into Germany within recent years, and attributes it to the peculiar methods prevailing in the German coal market. He indicates that the progressive concentration of the German coal production in a few concerns, the difficulties placed in the way of unfettered trade, the almost unavoidable necessity of using the syndicate's selling bureau, which practically ignores personal preferences for certain brands, and a price policy which prevents judicious purchases at favorable opportunities, have led the more important consumers to take means to free themselves from the dictatorship of the syndicate by the purchase of British coal, which enjoys the advantages of cheap transit by water.

Sir Francis says the price policy of the syndicate is the greatest help in the sale of British coal, and as long as it lasts the hold of British coal on the German market is not likely to be weakened by any lowering in freight charges by the railways in Germany. He adds that the question of an import duty on coal may safely be left to the German consumers, who are fully alive to the fact that, if they were deprived of the opportunity to obtain British coal, they would be at the mercy of the syndicate.

London, England. R. L. B.

Letter from a Working Fireboss

In regard to the examination of the mine by the fireboss, the Pennsylvania bituminous-mine law requires that the fireboss, three hours prior to the appointed time for each shift, shall examine, for all dangers, all portions of the mine in his charge; and at each examination shall mark the date, at the face and on the side of each place examined. He must, therefore, examine all haulageways and the entrances to all worked-out or abandoned places.

The law requires each miner to examine his place himself, before going to work, to see if the date has been left by the fireboss. If he does not find it he will know that the fireboss has not examined his place. He must then, at once, notify the mine foreman or his assistant before proceeding to do any work in the place.

Now suppose the fireboss should not examine a working place, through neglect or other cause, and the miner should enter the place and go to the head of the room in order to see if the date, which the fireboss should leave there, is marked on the face of the coal. It might be the last of the miner. To avoid this I think there should be a small blackboard placed at the entrance to each working place, and the fireboss should put the date on this board as well as on the face and side of the coal. The miner could then see if the fireboss had done his duty, by examining the board at the entrance to his place, before proceeding to the working face. If the proper date has not been put on the board by the fireboss, the miner should place his check number on the board and see that his working partner does the same; these check numbers to remain on the board till the fireboss makes his round the next morning or till he next examines the place. After the examination of the place the fireboss should erase all on the board and place there the date of the examination.

This system, if adopted, would allow the mine foreman or any other person to see and to know what men were at work. In case of an explosion the boards would show what men had entered the mine and were at work that day, in each working place.

A Pennsylvania Fireboss.

British Solution of Minimum Wage Problem

It will be recalled that one of the demands formulated at the recent convention of the United Mine Workers of America at Pottsville, Penn., was a minimum daily wage for miners. This point has been vigorously contended for at other times and in other fields—notably by the miners of Great Britain.

The following letter from a correspondent in Wigan, England, contains timely reference to this subject which will doubtless, before long, be agitated generally:

At Seaton Delaval, Northumberland, a scheme has been instituted under which the earnings of pick miners are pooled and equally divided. This experiment has a bearing on the agitation for a minimum wage. In this district some of the places are of unusual hardness, and other difficulties prevail with the result that some miners cannot earn a dollar a day, while others more favorably circumstanced are earning from three to four dollars.

Under the pooling arrangement referred to, it is claimed that one of the greatest hindrances to harmonious working will be removed, in so far as each man will receive the average wage of the mine. The further argument is advanced that under prevailing conditions this scheme which is now being tried will at once give the "minimum" the miners in Northumberland have applied for, namely 30 per cent. advance on the 1879 basis, always providing that the general body of the men work as hard under the scheme as they have done under the old system.

Of course, pooling has its disadvantages, the chief one being that while part of the men receive a substantial advance, the rest voluntarily suffer a proportionate reduction. Nevertheless, if the colliery companies cannot be prevailed upon to make some award or bonus to balance the "abnormal places" drawback, it really would appear that in the widespread adoption of pooling, the colliery communities of Great Britain will find the readiest and simplest solution of a vexing problem.

Wigan, Eng. B. A. W.

Essentials for Successful Management

It would be a mistake to assume that the office of mine manager is a sinecure. It is a life of perils escaped and victories won, with more or less contention with disasters and labor upheavals in the form of strikes. A mind almost encyclopedic in character is essential to secure the necessary acquaintance with all the sciences that may be applied by the mine manager; the foibles and idiosyncrasies of man himself have to be observed with the utmost tact; trivial causes that may be productive of much friction with the miners' union have to be avoided with the skill of a general; troubles and peculiarities of the strata have to be studied and overcome; while the contending forces of labor and capital have to be mollified—the one ever seeking higher pay for the work accomplished, and the other constant in demand for increasing dividends on capital sunk.

On the social side, of course, the manager is pretty much what he makes himself. As Henry Davies aptly puts it, he may be "the most abused man in the colliery village, because he assumes the rôle of petty tyrant, or one who by fair judgment, urbanity, and conscientious discharge of a difficult task, wins the respect of his workmen and the confidence of his neighbors. His power for good in molding the character of the men in his charge is incalculable. By means of the music hall, concert room, gymnasium, society building or lecture hall, he has channels through which he may support all progressive movements calculated to benefit the workmen, and inculcate habits of thrift and temperance." The latter is more necessary for the safety of the entire pit force than is sometimes realized.

Thus it is seen that while the position and life of the mine manager have their serious responsibilities, they also carry compensations and advantages that the humanity in man ever craves for. In coal mining the greater liberty and play this humanity is allowed, the easier the task, and the lighter the responsibility. In illustration of this and the pleasures to be derived, the story may be recounted of how William Bumpstead managed the Treeton House Colliery in Yorkshire, during the period when he raised the daily coal output from some 270 to 3000 tons. As to the condition of the mine under Mr. Bumpstead, after his last inspection H. M. Inspector of Mines said, "The Pit is in excellent condition, and one of the best in South Yorkshire."

How was all this accomplished? The reasons may be stated briefly:

(1) Mr. Bumpstead believes it is the duty of the man in authority to get to know his men, and make firm friends of them.

(2) He believes in giving a man a dollar for a dollar's worth of work, and urges all not to try to get a dollar's worth for 75 cents. He has never been asked or expected to pick workmen's pockets.

(3) He has been tolerant, and thereby invited tolerance, the best medicine when trouble is about.

(4) He has never been in too big a hurry to improve upon the management of his predecessors, having made it his duty first to find out the peculiarities of the pit.

(5) At no time has he imposed hardships on those under him for personal aggrandizement.

(6) Finding himself surrounded by a capable set of officials—civil, energetic, painstaking men—he made them feel that they were managers in their own particular districts.

(7) He encouraged coöperation with his under officials, and if at any time something went wrong a "confab" was sufficient to get matters right. From experience he finds that is the way to work. A comfortable set of men means better work, greater output and peace. Thus at Treeton they improved the outlook for the company, and in so doing the men shared in the benefits.

The foregoing may seem small things, almost too trivial to command a second thought, but they represented success in capital letters at Treeton. If your own colliery isn't the success you would like it to be, just run over the points again and ask yourself a question or two. It may pay you in the end.

Manchester, England. R. O. E.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Furnace Ventilation

Expecting to open a shaft mine for the development of a 5-ft. seam of good coal, it is desired to ascertain: (a) What ventilating pressure may be expected in the use of a furnace in this mine? The seam is practically level and the depth of the furnace shaft will be about 150 yd., including the stack. (b) What volume of air will this pressure produce when the mine is ventilated in two equal, separate splits starting from the bottom of the shaft? The size of all airways and entries is 6x10 ft., and the total length of airways, including return, may be estimated as 12,000 ft.

Pittsburg, Penn. A. C. M.

(*a*) Knowing the depth of the furnace shaft, the ventilating pressure that is possible to be developed in the mine, under usual conditions, may be calculated by the formula

$$p = 0.11 \sqrt[5]{D^4},$$

which gives, in this case

$$p = 0.11 \sqrt[5]{450^4} = 14.6 \textit{ lb. per sq.ft.}$$

(b) The entire rubbing surface in the mine is $2\ (6 + 10) \times 12{,}000 = 384{,}000$ sq.ft. The quantity of air circulated by the pressure just found, assuming two equal splits of the air-current, which makes the sectional area $2\ (6 \times 10) = 120$ sq.ft., is

$$q = 120 \sqrt{\frac{14.6 \times 120}{0.00000002 \times 384{,}000}} = 57{,}300 \textit{ cu.ft. per min.}$$

Sulphur in Coal

We have, in our mine, a considerable quantity of sulphur that occurs in round chunks and is separate and apart from the coal. This could be handled easily if it has any commercial value. Will you kindly inform me in regard to this? Can send a sample if necessary.

SUBSCRIBER.

Prestonsburg, Ky.

This deposit is the well known "sulphur balls," or iron pyrites, that occurs frequently in coal seams and the contiguous strata. Owing to the bright-yellow color, resembling gold, it has often deceived the miner, and has been styled "fool's gold."

Pyrites has a commercial value only where there is a demand for its use in the production of sulphuric acid or other sulphur products, and the cost of mining and transportation is not prohibitive. In general, it may be stated that the supply exceeds the demand, which fact makes only the best and clearest grades of pyrites marketable. The market value of pyrites carrying from 44 to 48 per cent. sulphur is about 9c. per unit, which means 9c. for each per cent. of sulphur in the ore as shipped, per ton. The value of the deposit must always depend on cost of transportation to the market, freedom from arsenic, and what disposition can be made of the associated or byproducts. In some localities, the existence of copper smelters, working on sulphide and producing sulphuric acid as a byproduct would destroy any possible market for the iron pyrites.

To Find Length of Sub-chord

Is there not a shorter method than that of proportion for ascertaining the proper deflection to be used in laying off sub-chords on a curve?

MINE SURVEYOR.

Yes. Multiply three-tenths of the sub-chord in feet, by the rate of curvature expressed in degrees and decimals of a degree; the product will be the proper deflection expressed in minutes. For example, the proper deflection for a chord of 15 ft. 9 in., on a 16 deg. 22 min. curve, is found thus; 15 ft. 9 in. = 15.75 ft., and 16 deg. 22 min. = 16.367 deg.; then, $0.3 \times 15.75 \times 16.367 = 77.33$ min. = 1 deg. 17 min. 20 sec. is the deflection for this chord, on the given curve.

Closing Force on Mine Door

A mine door measures 6x6 ft., and is made of inch oak boards doubled, and is hung with the upper and lower hinges 40 in. apart, the lower hinge being 5 in. out of plumb so that the door leans when closed, in the direction the air-current is moving; if the ventilating current be reversed, what water-gage will open the door?

FIREBOSS.

Area of door 6x6 ft. = 36 sq.ft.; thickness 2 in. = 1/6 of a foot; volume of door = 6 cu.ft.; weight of door with oak weighing 50 lb. per cu.ft. = $6 \times 50 =$ 300 lb. Now when the door is closed, it lies wholly in a plane inclined 5 in. in 40 in. or 1 in 8, to the vertical. A line at right angles to that plane is inclined, therefore, at 1 in 8, to the horizontal. This is the direction in which every point moves, for an instant of time, on opening the door, that is, at right angles to the plane in which the door lies or inclined at 1 in 8, to a horizontal plane.

The center of gravity of the door, which is the same point as the center of pressure of the air on the door, moves in that direction. As, therefore, the center of gravity moves momentarily up a grade of 1 in 8, the power required to move it, for that instant of time, is one-eighth of the weight of the door or 1/8 of 300 lb. = 37.5 lb. The area of the door being 36 sq.ft., the pressure per square foot must be $\frac{37.5}{36}$, or 1.0416 lb. per square foot.

The water gage required to open the door, after reversing the current, is, therefore, $1.0416 \div 5.2 = 0.2$ inch.

Estimating Quantity of Air

Is there any way by which we can ascertain the quantity of air flowing through an airway without using an anemometer to find the velocity of the air-current?

FOREMAN.

Yes. (1) The velocity can be found by observing the time, by the watch, that the smoke of a flash of powder takes to travel a certain measured distance, in a uniform section of the airway; then, multiply this velocity (feet per minute) by the area of this airway (square feet), and the product will be the required quantity of air (cubic feet per minute). Or, knowing how much air will circulate in this airway, under a certain water gage, the quantity of air for any other observed water-gage reading, in the same airway, can be found.

For example, if the water gage in this airway, yesterday, read 1.6 in., and you had measured the air then and found it to be 84,000 cu.ft., and today the water gage reads 2.2 in., assuming this increase of water gage is wholly due to an increase in the circulation, the quantity of air passing may be calculated by applying the principle that, for the same airway, the ventilating pressure and therefor the water-gage reading are proportional to the square of the quantity of air produced. Or, what is the same, the quantity of air produced is proportional to the square root of the water gage. Therefore, the quantity ratio is equal to the square root of the water-gage ratio. Now, calling the desired quantity of air x,

$$\frac{x}{84{,}000} = \sqrt{\frac{2.2}{1.6}} = \sqrt{1.375} = 1.1726$$

$$x = 84{,}000 \times 1.1726 = \textit{say } 98{,}500 \textit{ cu.ft. per min.}$$

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Interesting Questions

Strength of Crossbars or Collars

Ques.—(a) Explain as simply as possible the correct method of calculating the strength of a round or square crossbar or beam when the load on the beam is equally distributed along its length. (b) How does a center load compare with a load that is equally distributed, in its effect to break a beam or crossbar?

Ans.—Any beam or crossbar is considered as made up of a bundle of parallel fibers, each having a certain strength to resist a force of extension or compression—a pull or a push. In the case of a horizontal beam (Fig. 1) carrying a load, the weight of the load acts at right angles to or across the fibers. As the beam bends slightly the fibers in the lower portion are extended and those in the upper portion compressed. The strength of the fibers to resist this extension and compression determines the strength of the beam.

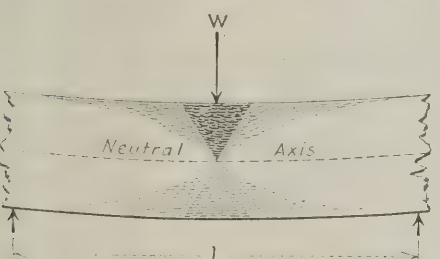


Fig. 1. Beam or Crossbar, Showing Graphically Effect of Bending

The force exerted to stretch or compress the fibers, per unit of section, is called the *fiber stress* and is estimated in pounds per square inch. The safe fiber stress is the safe load or stress, in pounds per square inch of section. For example, the safe fiber stress of different kinds of well-seasoned timber used in mining may be taken as follows, using a factor of safety of 6 for transverse loading:

Ash	1650	lb. per sq.in.
Yellow pine	1250	
Hickory	1100	
Oak, red cedar	1000	
Black walnut	800	
White pine, hemlock, spruce	750	
Poplar, birch	700	

(a) The center load w (Fig. 1) is supported one-half at each end of the beam. The reaction at each point of support $\left(\frac{w}{2}\right)$ acts with a lever arm of one-half the distance between supports $\left(\frac{l}{2}\right)$, giving a bending moment at center of beam $\left(\frac{wl}{4}\right)$ inch-pounds. This bending moment is resisted by and equal to the combined forces resisting extension and compression in the fibers, with respect to the neutral axis, which, for a beam of uniform section, is at the center of the beam. The combined effect of these resisting forces is found by multiplying the unit or fiber stress of the material by what is called the section modulus of the beam.

The section modulus is the moment of inertia of the beam's section divided by the distance from the neutral axis to the extreme fiber. For a round, square or rectangular beam the value of the section modulus is as given below, in Fig. 2.

To illustrate, the combined resistance of the fibers to extension and compression, in a round oak collar or crossbar 8 inches in diameter, which has a safe fiber stress of 1000 lb. per sq.in., and whose section modulus is $\frac{8^3}{10.186} = 50.265$, is $1000 \times 50.265 = 50,265$ in.-lb. To find what center load this crossbar would

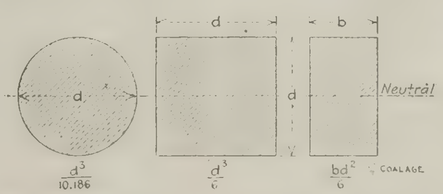

Fig. 2. Showing Value of Section Modulus for Circular, Square, or Rectangular Beam

carry safely, for a clear span of 10 ft. (120 in.), call this safe center load x; then,

$$\frac{x \times 120}{4} = 50,265$$
$$x = 1675+ \ lb.$$

(b) An equally distributed load is always double the center load producing the same bending moment.

In the use of this formula, it is both interesting and important to note that a crossbar will generally fail by shearing instead of bending, whenever the diameter of the beam is greater than 1/15 of the clear span, for a round beam (circular cross-section), and a uniformly distributed load; or 2/15 of the span, for the same section of beam, loaded at the center. For a rectangular cross-section, the beam will fail by shearing instead of bending, when the depth of the beam exceeds 1/20 of the clear span, for a uniformly distributed load; or 1/10 of the span, for a center load. In any of these cases, the safe load the beam will carry must be calculated by the formula for finding the shearing load; thus,

Round beams,

$$L = f_s (0.7854\ d^2).$$

Rectangular beams,

$$L = f_s (b\,d).$$

The safe unit shearing stress (f_s), or the shearing stress per square inch of section, for timber, may be taken as 1/15 of the values previously given for extension and compression of the fibers.

The practical application of the above is shown in the knowledge of the fact that an 8-in. round collar, uniformly loaded, will fail by shearing at the legs of the framing, on any span less than $\frac{8 \times 15}{12} = 10$ ft. The same collar will yield by bending on any span exceeding 10 ft. A 6x10-inch square beam uniformly loaded will likewise fail by shearing, on any span less than $\frac{10 \times 20}{12} = 16\frac{2}{3}$ ft., or 16 ft. 8 in.; and the same beam will bend before it will shear on spans exceeding this amount. The same rectangular beam, 6x10 inches, if loaded at the center, would shear before bending on spans less than $\frac{10 \times 10}{12} = 8$ ft. 4 in., and bend before shearing on spans exceeding this amount.

Ventilation—Circulation in Two Airways Compared

Ques.—Suppose two entries of the same length are ventilated by equal pressures, under like conditions; one entry is 8 ft. wide and 5 ft. high; the other is 10 ft. wide and 4 ft. high. Inasmuch as these entries have the same sectional area and equal lengths, why will they not pass equal quantities of air, for the same pressure?

Ans.—For any given ventilating pressure, the quantity of air in circulation in an airway is given by the formula

$$q = \sqrt{\frac{p\,a^3}{k\,l\,o}}.$$

Assuming that the pressures (p), areas (a), lengths (l) and the coefficient (k) are each constant, it is clear that the quantity of air (q) varies inversely as the square root of the perimeter (o). In other words, the quantity ratio is equal to the square root of the inverse perimeter ratio; or, since the perimeters of these two airways are $2(5 + 8) = 26$ ft., and $2(4 + 10) = 28$ ft., respectively,

$$\frac{q_2}{q_1} = \sqrt{\frac{o_1}{o_2}} = \sqrt{\frac{26}{28}} = \sqrt{0.92857} = 0.963.$$

That is to say for every 1000 cu.ft. of air that passes in the first airway there is 963 cu.ft. passing in the second airway.

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

Liquor Problem in Mining Communities

The Welfare Plan adopted by the Donahoe Coke Company, and discussed in my article last week, included more than the control of the liquor traffic—it comprehended the *secret* of that control which was, with the coöperation of the company, to place opportunity for better living conditions right in the hands of the employees.

Part of the main street and some of the yards were graded but not sodded. A few of the houses were wired for electric lights.

Families using the least liquor were given the best houses. Those whose beer record were not down to the minimum were given second-class houses, and the families that ordered the full amount of liquor allowed were given the "shacks."

The full allowance (except under special conditions) was five kegs per week to a family (including the boarders) if living in a "shack," three kegs if living in a second-class house and two kegs if living in a first-class house.

The rent was the same for all houses. Families with a low beer record could secure from the company, sod for their yards, lumber with which to construct sidewalks, fruit trees, flower seeds and things necessary in preparing and making gardens.

The Wife and the Beer Record

It was not long before "Mary" noticed the great change taking place in her neighbor's yard and house. "Mary" asked her neighbor how this change was made possible. She was told that if the family reduced the weekly beer record she could have a house on the graded street and secure the material with which to fix the yard and make a garden. "Mary" then talks with "John" and the boarders, and down goes the beer record.

Oh, yes, it hits a little hard at first, but "Mary" must keep up with her neighbor. How many men in our cities have purchased pianos and automobiles just because their "Mary" would "break her heart if she could not keep up with her neighbor, Mrs. Goldbanks." Yes, it goes a little hard with "John," but he also gets the "desire" as time goes on. As one miner (a Slav) at Crabtree said to me: "Yes, like to live in best house (and he pointed with pride to his house and garden), but three kegs of beer a week not much for five boarders, but, well, more money save, nice house and feel good." "But how about the superintendent, does he always keep his promises," I asked. "Oh, yes, Mr. Super alright. What he say he do it, he do. Boss alright."

What is the secret? A welfare plan that restricts the use of liquor, but makes the securing of all benefits that better the living conditions depend upon the initiative of the family—we say "family" as "Mary" is the "reformer in the house."

To give some of the beneficent results of the work of the Greenwald Committee: By September, 1911, so many families had graduated into the better-class houses that the company removed all but two of the shacks.

Houses Fenced and Streets Graded

The Last of the Old-time Shacks

A Back Yard As It Used to Be

One of the Back Yards Today

Company Encouraged to Extend Welfare Work

To keep pace with the social and moral advancement of the people of the community the Donahoe Coke Company has graded another part of the main street, put electric lights in 16 houses, a bath tub in one house, painted several of the first-class houses over, not with the regulation prison-house garb, company-house-red, but different houses with different colors, with five distinct colors to be exact. The yards have been

fenced and coal houses and garbage chutes built at the rear of each lot. A sanitary officer is employed and he has the teamster collect the garbage daily.

The company has arranged with a farmer to supply all families with good fresh milk daily at *five cents a quart.*

The Welfare Fund supplies each family with free ice. One hundred pounds is delivered to each house every Wednesday and Saturday and Mr. King states, "We are building a chicken house for each family and are preparing to establish a large fruit-, shrub- and shade-tree nursery from which we will supply each family with trees for the yard as fast as a definite desire to have and care for the trees is exhihited."

The company is also planning a complete sewerage system and a plot will be surveyed upon which will be built several blocks of single houses.

Play grounds for the children will be added later, when the community life has reached the point that the initiative of the people themselves will create the natural demand.

Applicable to Large and Small Communities

Some operators may say, "The plan may work at a small operation but it would fail in the larger mining towns." Mr. King says, "Our handicap is due to the small size of our plant and lack of sufficient houses. If we were employing a large number of miners we could work out our plans much better. The solution of many problems is to secure an atmosphere of home contentment and each workman and his family should be furnished with a home of such a type as will secure privacy and then they should have an opportunity to fix it up and feel that they are, at least, human.

"We have experimented enough to learn that the foreigner, like ourselves, desires something to call his own, some way by which he may express himself and feed and develop his own individuality. Permit him to construct his own walks, plant his own trees and flowers and he is much more contented than he would be if you were to do it for him.

"This plan works to the betterment of the men and their families and since it has been in operation *our tonnage has not been reduced one ton of coal through the use of liquor by employees."*

Of course the superintendent of a mine could not successfully promote a plan so comprehensive as that of the Greenwald Welfare Committee without the full sympathy and coöperation of the company. It goes without saying that Mr. King has had that coöperation. In fact, John P. Donahoe has personally interested himself in every detail of the work and a statement of his views should be instructive and of interest to all mining men who are giving attention to the liquor problem and the welfare of the mine employees.

The Company Approves Welfare Work

In a conversation recently Mr. Donahoe stated among other things that "To carry on a work such as that of the Greenwald Welfare Committee the men must first of all have implicit confidence in the word of the superintendent." "Do not keep the 'company' constantly before the eyes of the men. We use the name Greenwald Welfare Committee to avoid an undue reference to the Donahoe Coke Company."

"The plan to be successful must be one where initiative is required on the part of the men and their wives." "Our best temperance reformer is the woman in the home." "You would suppose our bosses live in those newly painted houses. Well, a Slav teamster lives in the first house and a miner lives next door.

First-grade Houses, Each Painted a Different Color

Two Side Yards, Showing Flowers and Shrubs

First Aid Hints

An improvised stretcher can be made of a couple of jackets, with sleeves reversed. The coats are laid tail to tail. Poles are passed through the reversed sleeves and the coats buttoned up.

A burn should not be exposed to the air a minute longer than is necessary. Interfere as little as you can with the surface of the burn before dressing. If you distinctly see foreign bodies on the surface, remove them before applying the dressing. But under no pretext drag or pull at anything adhering to the wound. Cut away clothing with scissors.

With extensive burns, uncover and dress a small portion of the burnt surface at a time, in order to reduce the pain of the operation as much as possible. Never pull the clothing off a burn; always cut it away. Cover all exposed burnt surface immediately.

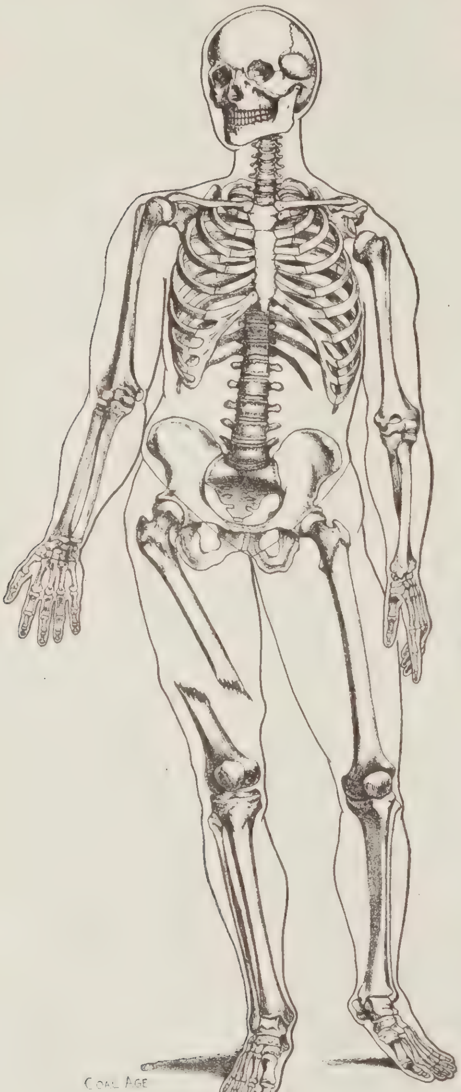
All first-aid supplies should be kept in a tightly closed receptacle in order to keep them free from dust. Never handle unless absolutely necessary. Packages of dressing should never be opened or the paper cover in any way broken until they are about to be used, as it takes only a slight touch to render them septic. Remember that water, though it seems pure, is not sterilized, unless rendered so by special treatment, and wounds washed with unsterilized water, or bandaged with bandages which have been handled, are apt to give trouble. Septic bandaging is worse than none at all.

In case of a fractured spine, which is of comparative frequency in mines, the first-aid man can render little assistance, except to insist that the patient be kept flat upon his back, as placing him upon his side or face for any length of time may kill him. If the spinal cord is not torn, one of the best things for the first-aid men to do is to make a cradle splint. This consists of four boards, two long and two short, 1 in. thick and 3 in. wide. The shorter splints should be about 18 in. long and the long splints from 4½ to 5 ft. long. Place the splints 3 in. apart, then nail or bandage them together as circumstances permit. Pad with anything which can be procured most quickly. With one motion turn the patient on his side, rest the splint on his back, lay him back again flat upon the ground, and bandage securely the shoulders, hip joints, knees and ankles. All work on patients suffering from spinal injuries should be most carefully done as additional jar to this great nerve center may mean immediate agony and death in the near future. A set or sets of the splints above described kept near the working faces would do much to relieve the pain of many an injured miner.

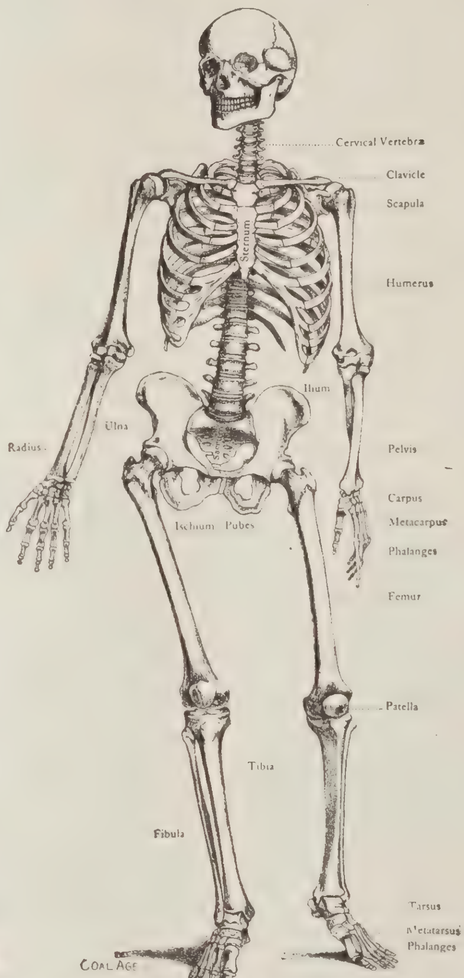
Physiology and First Aid

The illustrations below are the same as are exhibited in the Red Cross cars and published in the "First Aid Manual" of Lynch and Shields. The central figure shows the bony structure of the body with the names of the various parts. It is necessary for the first-aid man to know where the bones lie, but this is not that he may put them back into place. That is not his work. But it does give him an idea how he can keep in line the bones which have been fractured and not displaced. It is an unfortunate fact that the "subjects" on which first-aid men must practise, are men with limbs and trunk in perfect line. Fractures occurring from the misfortunes of industry, are frequently badly compounded. The *physical* training of first-aid men does not cover such fractures, and training by word of mouth does not persist in the memory like information entering the brain by the eye.

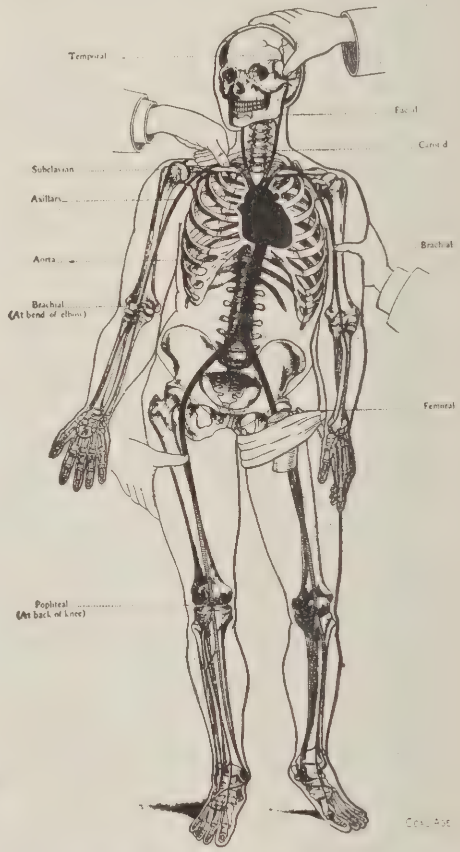
The following words from the manual mentioned, should be impressed on those who will act as aids to the absent physician. "If a sharp bone is buttonholed through the skin, as frequently happens, do not attempt to restore it to its place, but by padding the splint hold the bone in position *just as it is.*" Clearly should it be retained in mind that the fractures we shall dress in the mine are not the same as the imaginary fractures seen on the Forbes field and any fracture which does not leave the bone in place is particularly hard to correct. The returning of the section thus displaced by a lay worker will frequently lead to a severed artery and torn ligaments.



SHOWING DISLOCATION AND FRACTURE



SHOWING BONY STRUCTURE OF BODY



VIEW OF ARTERIES AND BONES

A Knowledge of the Location of All Arteries is Most Essential

The right-hand illustration shows arteries and bones in a single figure. At once is clear the value of a knowledge of the bony structure, because arteries cannot well be pinched and their blood flow controlled where there is no bone nearby to form the hard wall against which the pulsing artery can be deformed to such a degree that it cannot pass blood.

Very clearly with all reference to venous-blood passages omitted, the arteries are outlined, backed by the bones which protect them and against which they can be compressed and deformed. The hands of first-aid men are shown compressing these arteries at the appropriate places and this makes it easy to understand where the blood-flow can be controlled to the skull, the upper half of the arm, the forearm and the leg. In the latter case a compress is shown deforming the femoral artery against the femur of the left leg.

The other illustration here reproduced shows the dislocation of the left arm, the whole member being drawn down so that the upper joint of the scapula no longer turns in the socket of the clavicle. The upper right-leg bone or right femur is fractured and as the parts are separated the fracture is compound. It might be suggested, however, that the sketch of this fracture is not true to life and does not suggest the difficulties of treatment naturally arising out of such a violent break in a bone.

Mistaken First Aid

An incident may be noted here concerning a Japanese miner in one of the large Western mines who had his arm broken. His fellow countrymen immediately proceeded to load him up with two quarts of whisky, and on the mine-surgeon's arrival he was greeted by a most hilarious patient, proudly waving a bloody and dangling stump, and surrounded by an admiring throng of countrymen. It is needless to say the arm was lost and nearly the life as well.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Taylor Vincent, of West Virginia, representing the United States Coal and Oil Company, of that State, as well as a considerable number of small coal producers, appeared, on Nov. 16, before the Senate Committee on Interstate Commerce, which is holding hearings with reference to anti-trust legislation, and on behalf of his clients recommended to the committee that it report a bill for the establishment of a body to be known as the United States Mining Commission. Mr. Vincent affirmed that the plan was approved by the industry as a whole.

This commission would be composed of five men skilled in the business of mining and selling coal, to be appointed by the President of the United States, with the advice and consent of the Senate. The powers which Mr. Vincent desires to have conferred upon the commission are set forth in a bill which he submitted. This provides in substance (Section 6) that the commission be authorized to sanction trade agreements between competitors engaged in interstate commerce, providing for a joint selling or purchasing agency, whenever, in the judgment of the commission, such trade agreements will not unreasonably restrict competition nor raise prices beyond a point justified by the supply and demand. The bill also provides (Section 7) that the commission be authorized to enforce regulations to secure the safety and health of the employees engaged in and about coal mines, and enforce regulations to prevent waste and conserve the unmined coal.

The Arguments Advanced

Mr. Vincent's argument for his proposition is that the existing state of affairs in the bituminous coal-mining industry is so unsatisfactory that some immediate remedy must be had. The remedy desired is the power to make agreements for the fixing of prices, subject to the general control of the Government. In describing the present condition of the industry he made the following statement: "The average sale price through the whole country for 1910 was \$1.11 per ton. The actual cost of producing this coal was \$1.07 per ton, excluding interest and depreciation for the coal mined and exhausted. The item of depreciation will amount to 4c. per ton, while the interest on the investment of \$585,000,000 is \$35,100,000, at 6 per cent. The selling price of coal has remained stationary for the last six years, being \$1.10 in 1904 and \$1.11 in 1910, with an extreme fluctuation of only 8c., while the cost of producing the coal has increased 9c. a ton during that period.

"The consumers of bituminous coal in the United States pay less for their fuel than in any other country in the world. The other branches of industry in this country have been profiting at the expense of the bituminous-coal business, and the only possible way that this industry can protect itself from ruin is by combination, and they dare not combine as long as the anti-trust law hangs over them with its threats to prosecute criminally and dissolve their organization if they do combine."

The Senate committee showed comparatively little sympathy. Some members objected to the substitution of an administrative commission for the courts, while others felt that the granting of permission to make trade agreements was not paralleled by sufficient power to prevent the pushing of the agreements to a point where they would be dangerous or disadvantageous to the community. There was also considerable criticism of the proposal to establish a system of compensation for mine accidents, inasmuch as it was felt that this matter was already under the jurisdiction of the employer's liability commission, acting jointly for the House and Senate.

The Pittsburg-Lake Coal Rate

During the past week, the Interstate Commerce Commission has been engaged in hearing argument in the so called Pittsburg coal-district case: "John W. Boileau in his own behalf and in behalf of shippers of Lake coal from the Pittsburg district against the Pittsburg and Lake Erie Railway Company and others."

Oral testimony was presented by Vice-president James E. Walsh, of the Pittsburg Coal Company and others. Mr. Walsh declares that the present 88c. per ton rate on coal is excessive and that the company makes no profit on coal mined for the Lake traffic. He said that his company was doing business at a loss and was holding on in the hope of relief in the future. His company, according to Mr. Walsh, has been crowded out of the markets by West Virginia coal, as to which, he alleged, there was discrimination in rates.

The other coal witnesses worked along much the same lines and presented more or less familiar facts. Probably the most significant development of the week has been the filing of elaborate exhibits in behalf of the Pittsburg Coal Company, wherein various methods of computing freight rates are set forth in detail and on the strength of the results a reduction from the existing rate is demanded.

Alabama

Birmingham—The Sloss-Sheffield Steel and Iron Company, and the Alabama Consolidated Coal and Iron Company, have withdrawn from the Alabama Coal Operators' Association. It is understood that these companies are dissatisfied with the action of the Tennessee Coal, Iron and Railroad Company and other members of the association in adopting semi-monthly in place of monthly pay-days at their coal and ore mines.

The plan for the merger of the Alabama Consolidated Coal Company and the Southern Iron and Steel Company, it has been stated, will be altered to include the offer made recently by President Hoadley, of the Alabama company, to the dissatisfied preferred stockholders of the Alabama Consolidated Coal and Iron Company, namely: 30 per cent on common stock, in addition to the 150 per cent. of preferred, which they were to receive under the merger plan as originally prepared by the committee.

California

San José—Suit was recently brought against the Monterey Coal Company by A. B. Campbell, who, as assignee of Campbell, Foster & Co., demands over \$331,000, as commissions on sale of the coal company's stock.

San Francisco—The Canadian Collieries Company, a British concern of great size, has announced the establishment in this city about Dec. 1 of sales offices and headquarters.

Colorado

Coalmont—A shaft has been sunk here 135 ft. by the Northern Colorado Coal Company and rooms are being turned off in the workings. The track of the Laramie, Hahn's Peak & Pacific railroad is within less than three miles of here, and it is expected that the mine will be ready to ship coal by the time the railroad is completed.

Denver—Labor troubles in the coal camps of northern Colorado, where a strike has been in progress for some time, have reached a stage where the advisability of calling for troops is being considered.

At Louisville the situation is regarded as particularly critical. The mines there are owned by a Wyoming corporation. President Brown, of the company, on Nov. 28 said unless conditions improved within the next two days he would ask Governor Shafroth for the protection of Federal troops, to which, he says, the company, as a nonresident property holder, is entitled.

Since Saturday, Nov. 25, it is reported, the union and nonunion miners have been in practically open warfare. Strikers and women sympathizers paraded the streets, flourishing revolvers and other weapons and making threats to strike breakers entering the camp.

Illinois

Marion—The closing of the lease of the Saline Valley Railway Company by the Big Four, gives the New York Central an entrance into the coal section west of Marion. The Saline Valley line is unbuilt as yet, but bonds to the amount of $3,000,000 have been issued. The line will be short, only 22 miles, but will open up valuable coal territory.

Centralia—Fire broke out in the Junction City mine, Nov. 18, imperiling the lives of many miners. The blaze was started while a shot was being fired, and gained strong headway. Several narrow escapes of miners were reported.

Springfield—The property of the Spaulding Coal Mining Company, at Spaulding, will be sold in the near future to satisfy a claim of $40,000, held by the Illinois National bank of this city. The Spaulding company is in the hands of a receiver.

Railroads in this district report a larger traffic than usual for this time of year. Mines throughout the region are working five days a week and a shortage of empty cars is felt at some points.

It is understood that an effort is being made by St. Louis operating companies with mines in Illinois to get some action by the Illinois operators on a proposition to ask the Senate Committee on Interstate Commerce to authorize trade agreements in the coal industry under the supervision of a national commission.

Du Quoin—With the idea of familiarizing miners with the latest methods and devices for fighting mine fires, J. C. Duncan, superintendent of the Illinois mine-rescue station at Benton, has arranged for a school of instruction in Du Quoin from Dec. 2 to 16.

Peoria—Miners at the Champion shaft east of town quit work recently, after a disagreement with the management over the shot-firing question. The men have been firing their own charges, but have insisted that shotfirers be employed by the mine operator, and after a conference decided to walk out. The management, it is understood, has decided to confer with other operators before coming to a conclusion.

Indiana

Indianapolis—The Equitable Mining Company, capitalized at $80,000, has filed articles of incorporation. The object of the new corporation is the mining of coal, lead, zinc, etc. The principal offices will be in Indianapolis.

Booneville—A sympathetic strike involving several hundred men is on at the Kapp's mine, west of here, in the Warrick County field. The reason advanced for the strike by the miners is that some of the men were laid off by the mine management in order, as they claimed, to make some repairs to the mining machinery. The work of making the repairs not going forward, the balance of the men were ordered to strike out of sympathy with the men laid off.

Kentucky

Louisville—The Pond Creek Coal Company has been organized by Hayden, Stone & Co., of Boston, Mass., with a capital stock of $2,000,000, to develop 30,000 acres of coal lands recently purchased in Pike county. The management of the new company will be identical with that of the Island Creek Coal Company. The property will require but little railroad building to give it excellent transportation facilities and immediate development is contemplated.

Henderson—The property of the Southern Coal and Transportation Company, at Robards, Ky., valued at about $200,000, is to be sold to satisfy creditors.

Pineville—Thos. Cairns, of Bell county, has purchased from the Louisville Property Company, which is allied with the Louisville & Nashville Railroad Company, its holdings in Bell and Whitley counties for a consideration of $1,800,000. The lands conveyed embrace a considerable portion of the Chenoa mining district. There are fourteen going coal mines on the Bell and Whitley county land. In addition there are also thousands of acres of timber lands. Mr. Cairns announces his intention to dispose of the property acquired, either by leasing or selling. He has been identified with the Louisville Property Company since 1886.

Barbourville—Work has been started on the extension of the Louisville & Nashville railroad's Wasioto and Black mountain line up Meador creek from Harlan to Agres creek, a distance of five miles.

This extension will pass through the boundary of 10,000 acres of coal land recently leased by Sneed, McGuire & Farmer. These lessees will sublease seven parcels of this boundary of coal and will operate one tract of 2500 acres themselves.

Morganfield—The Bell-Union Coal and Coke Company, at Curlew, Union county, has replaced the tipple recently destroyed by fire and is about to resume operations.

Minnesota

Duluth—Work will be commenced within a few days upon the building of a coal dock involving a capital expenditure of over $1,000,000. After negotiations extending over several months, the Island Creek Coal Company, the principal in the enterprise, has purchased a waterfront site containing about 30 acres. The price paid for this was in the neighborhood of $100,000.

The dock to be built will cover the entire property, and will have a storage capacity of 750,000 tons, or a coal handling capacity during the season of 1,500,000 tons. It will be equipped with steel bridges and the most modern type of machinery. Outside of the Pittsburgh Coal company's dock No. 7, the new dock will rank as the largest at the head of the lakes.

Missouri

St. Louis—It is reported that the Hawley-Erb syndicate has purchased the Novinger coalfields, Adair county, Mo., and that the proposed extension of the Iowa Central system to St. Louis will be through this district. Heretofore the Novinger fields have been local to the Quincy, Omaha & Kansas City, a Burlington subsidiary.

The Hawley interests have obtained permission from the Iowa Central executive council to issue $10,000,000 additional securities.

The Kolb Coal Company, of St. Louis, operating mines at Mascoutah, Ill., has placed a contract with the Ottumwa Box Car Loader Company, of Ottumwa, Ia., for a modern steel tipple. The tipple will be of the "A" frame design, and will be complete with self-dumping cages, weigh pan, reciprocating feeder, shaker screens and steel bins for diverting coal to the various cars.

The mine is located within 18 miles of St. Louis, and will, when completed, be one of the most modern operations in Illinois. The plant is expected to be completed and loading coal by Dec. 25.

Ohio

Crooksville—Work will be resumed at the Carding mine after 18 months' idleness. Two hundred and fifty men will be employed by the Elk Fork Coal Company of Wellston, which acquired the mine at receiver's sale. Plans and specifications have been adopted for the rebuilding of the tipple and the installation of uptodate mining machinery. Work on the improvements will be started immediately and will be completed by April, it is thought.

Bridgeport—The Jefferson Coal Company has abandoned its Piney Fork mine where the men have been on strike for two months and will open a mine abandoned years ago. Only those men from Piney Fork who were not implicated in calling the strike will be employed.

Cleveland—The Philips Coal and Coke Company, of Cleveland, has changed its name to the Equitable Coal and Coke Company.

Columbus — Plans for opening the sealed up portion of the Black Top mine, located near Cambridge, Guernsey county, in which one man lost his life recently and 11 others were overcome by a fire, are being made by the State mine inspector. Samples of gas have been collected from the portions of the mine which are sealed up and if the analysis proves satisfactory the mine will be reopened.

Oregon

Marshfield—The Millicoma mine on the east shore of Coos bay, which for the past two years has been developed by J. A. Ward, has been sold to the Millicoma Development Company, a new corporation. The development is practically completed and the new company will put the coal on the market. The company has 430 acres of land, under which it is claimed there are 10,000,000 tons of coal of high grade. The shaft has been sunk 275 ft. and it is possible to load the coal from bunkers directly onto vessels.

Pennsylvania

Bituminous

Connellsville—Idle since April 1, last, fires have been lighted at the Garwood plant of the Dunlap-Connellsville Coke Company, near Brownsville; the activity will continue at least until Feb. 1, and the management believes longer. Fifty-seven of the 119 ovens are in operation and the others are being put in use as rapidly as possible.

The Republic Iron and Steel Company is reported to be firing the 138 ovens at its Atchison plant near Cheat Haven.

Uniontown—It is understood that 80 additional ovens at the Connellsville Consolidated Coal and Coke Company's plant at Mt. Sterling will be fired as rapidly as the necessary mine labor can be secured.

Johnstown—The Smokeless Coal Company is opening a new mine near its present operation at Ferndale. This will probably double the present output from the local plant.

Strikes are in progress at the Amsbry mine of the Pennsylvania Coal and Coke Company and at the Nant-y-Glo Coal Company's mine. The grievance in the first case is reported to have arisen over the discharge of several motormen and in the second case because of an occasional lapse of three weeks between pay days.

Butler—The strike at the Sherwin coal mines at Karns City has been called off after six weeks' duration.

It is understood that construction of the Shawmut railroad will be resumed and that the line will be extended along the west bank of the Allegheny as far as Limestone Run near Kittanning. Work on the section of the road which runs down the Mahoning creek is progressing.

Anthracite

Scranton—The Delaware & Hudson Coal Company are dumping rock and slate on the hollow ground above the Delaware Breaker in preparation for laying additional tracks which will be used for empty cars. It is said a new breaker will be erected in the early spring.

The People's Coal Company recently acquired the rights and leases for 18 tracts of land in West Scranton from Mrs. H. A. Crawford.

Wilkes-Barre—The Exeter Machine Company in West Pittston is said to be going into the coal business on a small scale by erecting a washery near the old Exeter shaft. The company purposes using up the culm bank there for fuel at its plant.

Pottsville—Suit to recover $191,213 in royalties on coal mined has been brought against the Philadelphia and Reading Coal and Iron Company by administrators of the estate of Hugh Bellas.

The Philadelphia syndicate which has taken over the abandoned Lawrence, Bear Ridge and Stanton collieries near Girardville proposes to pump out the old workings and work the deep-lying veins which have never been mined. Pumping operations have been started but since it is estimated that more than two billion gallons of water will have to be removed, the work will probably take some months. It is said three slopes will be put down and modern breakers erected.

Washington

Spokane—Settlement of the coal miners' strike in the provinces of British Columbia and Alberta has greatly brightened the outlook for the mining industry in the Spokane country. By the agreement for a period of three and a half years from date the smelter and mine operators are given assurance of an ample fuel supply for that time.

One of the earliest results of the settlement will be the resumption of operations by the Granby company's mines and smelter. Six hundred men went to work on the properties in the Boundary district on Nov. 21 and 350 others will be employed as soon as coke is received from the Crow's Nest district. The company is finishing the No. 3 outlet to the Phœnix properties and is getting the bins and crusher in shape to handle a large tonnage, a number of men being put to work during the week to hurry the completion of the work.

Andrew Laidlaw, of Spokane, recently bought the license rights to 12 coal claims, each of 840 acres, on the Flathead river, in East Kootenai, 12 miles south of the Corbin Coal Company's property. These claims extend eight miles north and south along the course of the river, and are said to contain the same series of coal seams found to the north and immediately adjoining on the south. They also are reported to be heavily timbered.

West Virginia

Charleston—Among the new coal companies chartered here recently was the New River & Ohio Coal Company, of this city, to develop coal, iron and other mineral lands. The authorized capital is $100,000.

The American Coal Company of Pittsburg was recently granted a charter from this State. The concern is capitalized at $200,000.

The Horgart Coal and Coke Company, owning 2200 acres in Barbour county, has voted to develop the property.

Wyoming

Kemmerer—The Lincoln Coal Company has leased the properties of the Elk Coal Company and these are now being actively operated.

Canada

British Columbia—Coal from the mines at Lethbridge, Alberta, was placed on the market, Nov. 22, two days after the striking miners returned to work in this district. The agreement between miners and operators was signed at Hosmer, Nov. 17.

Coal mines at Fernie and Coal Creek, shut down since last April, resumed operations on Nov. 20. Mine and railway cars have been rushed in so there will be no delay in bringing out the coal. The miners apparently are well pleased to have their struggle over and be at work once more. Five hundred men are employed on two shifts, and these will be increased as rapidly as conditions permit.

The Columbia Coal and Coke Company is busily engaged in building two long railroad sidings on its property, at Coalmont. These will be ready to connect with the Great Northern by the time that company has its tracks laid into Coalmont.

Toronto—The British Columbia coal strike having been settled and work at the mines resumed, the Canadian government has reimposed the duty on coal imports into western Canada, which was temporarily remitted on July 31. The duty will be restored on Dec. 6.

Personals

James Richards, of La Salle, Ill., is appointed superintendent of the Spring Valley mine, at Dalzell.

J. R. Sharpe has resigned the position of resident superintendent of the Springhill Collieries, and has returned to his home in West Virginia.

Charles B. Spencer has been made general manager of the Pittsburg and Midway Coal Company, of Pittsburg, Ill., vice John N. Hodges, who has retired.

Richard Kirby, who has for the past three years been the mining engineer of the Dominion Coal Company, has resigned his position and returned to his home in Scotland.

C. A. Winehart, of Menominee, Mich., has been appointed northwestern manager of the Hutchinson Coal Company, Fairmont, W. Va., with headquarters at Green Bay, Wisconsin.

M. J. Caples has been appointed vice-president in charge of transportation on the Chesapeake & Ohio railway. Mr. Caples has a thorough knowledge of both the mining and transportation of coal.

George D. Evans, for the past six years engaged in the development of properties in West Virginia for the E. E. White Coal Company, has opened a general civil- and mining-engineering office in Pottsville, Penn.

Percy E. Wright, for the past ten years a sales engineer in connection with the home office of the Jeffrey Manufacturing Company, has been made manager of its newly established branch office in Seattle, Wash.

W. W. Taylor, for several years general superintendent of the St. Paul Coal Company, has been elected president of the company, with offices at Ottawa, Illinois. F. E. Fernekorn, former chief clerk, has been elected secretary.

E. B. Francis, who has been connected with coal and iron companies for a number of years, has been made treasurer of the Hocking Valley Products Company, which is a reorganization of the Hocking Coal and Iron Company.

Dr. J. A. Holmes, director of the U. S. Bureau of Mines, spent Nov. 18 in Birmingham, Alabama, inspecting the recently completed mine-rescue station. He was accompanied to Birmingham by Dr. Eugene A. Smith, State geologist of Alabama.

Señor Abraham Ferriz, the Mexican government engineer, accompanied by a party from the U. S. Bureau of Mines made an examination, Nov. 15, of the mine fire at the Pittsburg & Eastern Company's No. 2 mine at Cherry Valley. The party was in charge of O. H. Reinholt.

Societies and Technical Schools

The winter meeting of the West Virginia Coal Mining Institute will be held at the Masonic Temple, Fairmont, W. Va., Dec. 4, 5 and 6.

The Coal Mining Institute of America will hold a joint meeting with the Engineers' Society of Western Pennsylvania, at the headquarters of the latter in Pittsburg, Dec. 19 and 20. This is the regular winter meeting of the institute.

Coal and Coke Patents

United States

Coke-oven door; Louis Wilputte, Joliet, Ill., No. 1,006,036. This coke-oven closure comprises, briefly, an inner plug door having a firebrick insulation and an outer door furnished with means for sealing it against the jambs. Both doors are entirely detachable and may be removed bodily from the oven by means of lifting hooks.

Car for quenching coke; Hans Ries, Munich, Germany. No. 1,006,281.

Great Britain

Improvements in apparatus for the observation of gas caps and testing miners' safety lamps; O. Oldham, Denton, Manchester. No. 26,534 of 1910.

Coal cutters; W. L. Spence, Glasgow. No. 27,517 of 1910.

Improvements in magnetically locked miners' safety lamps; R. Cremer, Leeds. No. 1665 of 1911.

Improvements in relighting devices for miners' safety lamps; E. A. Hailwood, Morley, Yorks. No. 17,089 of 1911.

Industrial Items

The Vinton Colliery Company has established the headquarters of its management and sales at No. 1 Broadway, New York. The office formerly located in Philadelphia has been given up, but the company has salesmen calling on the trade in that vicinity. It finds that it is in a better position than ever to handle business in the Philadelphia territory.

The Jeffrey Manufacturing Company, of Columbus, Ohio, manufacturer of mining, elevating, conveying and power-transmission machinery and coal-mine equipment, has recently opened another branch office at 1201 American Bank building, Seattle, Wash., from which it will handle its business in the Northwest. This company is maintaining 13 branch offices in the United States, as well as nearly 100 agencies in the leading commercial centers all over the world.

The Wellman-Seaver-Morgan Company, Cleveland, O., has received an order from the Canadian Pacific Railroad for a $500,000 coal-handling plant to be erected at Fort William, Ont. The plant will include a bridge, two Hulett unloaders, coal conveyer cars and a trestle. Considerable electrical power equipment will also be required. An interesting fact in connection with this contract is that it is the first order that has been taken for Hulett unloaders for handling coal, as hitherto they have been used exclusively for handling ore.

The American Blower Company, of Detroit, Mich., with a factory also at Troy, N. Y., and numerous branch offices, has come to realize the importance of the Dominion of Canada, as evidenced by the application just filed for a charter for a company to be known as the Canadian Sirocco Company, Ltd., of Windsor, Ont. The Canadian Sirocco Company will hold exclusive patent rights for the manufacture in Canada of Sirocco fans and blowers and will also manufacture the full line of American Blower Company products, consisting of fans, blowers, heating, ventilating, drying apparatus, steam engines, steam traps, etc.

Trade Publications

Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y.; Bulletin No. 1002 second edition, 7¾x10 in. 38 pp. descriptive of local battery telephones.

General Electric Company, Schenectady, N. Y.; Bulletin No. 4886, 8x10½ in. 59 pp. "Electricity in Coal Mines." A number of interesting installations are described and illustrated.

Roberts & Schaefer Company, Chicago, Ill., Bulletin No. 23, 6x9 in., 32 pp., descriptive of Holmen Locomotive Coaling Stations. Twenty-five plants are attractively pictured and described.

The Jeffrey Manufacturing Company, Columbus, Ohio, bulletin No. 18-B, 8x10 in., 8 pp., descriptive of the Jeffrey-O'Toole coal cutter, a machine built to cut a kerf at various hights, depending upon the thickness of the coal seam.

Jeffrey Manufacturing Company, Columbus, Ohio, Catalog No. 50, 6x9 in., 142 pp., "Power-Transmission Machinery," giving complete lists of Jeffrey products in this line, including shafting, sheaves, pulleys, gears, etc. Sizes, dimensions and prices are given, also convenient engineering formulas.

Link-Belt Company, Philadelphia and Chicago, book No. 111, 6x10 in., 88 pp. "The Handling and Preparation of Coal at the Mine." This pamphlet illustrates and describes installations of tipples, washeries and conveying machinery for coal mines; also the detailed equipment for such installations as furnished by the Link-Belt Company.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The predominating feature in the coal market during the past week has been the car supply; this is reported, almost without exception, as inadequate, and in some instances acutely so. Unusual strength has developed in steam-coal prices, which is credited to the heavy buying, incident to a general improvement in business conditions.

In the extreme East tonnage reports are higher than for the same period last year, despite which stocks are being seriously depleted and new arrivals are slow. Pittsburg reports bituminous as steady and improving, with some activity in coke resulting in the letting of several important contracts.

Lake shipments from all Eastern ports have been unusually heavy this season. This is believed to be due to meager supplies in the Canadian Northwest, because of the labor troubles in the Crow's Nest during the summer. There is no improvement in the car situation in Ohio, while in some districts to the south conditions are such that the railroads are absorbing entire outputs for their own use.

Lack of motive power and proper equipment has resulted in a slow movement in the Middle West. This, together with the heavy snows and lower temperatures, has tended to deplete supplies and increase consumption, with a consequent improvement in the market.

Mines in the Rocky Mountain States are hopelessly behind orders, and in many instances working half capacity because of poor car service. There is a marked increase in the Pacific Coast trade, and both rail and water shipments are slow.

Boston, Mass.

There is little change, except in some quarters the situation grows more acute. Marine freights are now strong at $1.10, Hampton Roads to Boston, on large tonnage, and the same rate has been paid on 2500-ton barges to Providence. The shortage on vessels continues, and more shippers are obliged to go into the market for bottoms to make up for the slow movement of transportation or to replace boats that are lost. On car prices, Mystic Wharf, Boston, and at Providence as well are therefore up to new figures, $3.90 to $4 for spot coal, and very little is to be had at that.

On Nov. 27, the Boston retailers advanced their price on soft coal to $4.50, net tons. All-rail bituminous is showing improvement. Prices on the Clearfields are from $1.00 to $1.15, and extra business is being had nearer tide-water than the summer range on Southern coals would permit.

The anthracite companies are swamped with orders so that the situation on stove and chestnut sizes is rapidly getting serious.

New York

Considerable improvement has been noted here in the market for soft coal during the past week. There has been a marked increase in the spot demand for high-grade steam coals and some betterment in the demand for inferior grades. Contract movement is quite heavy and at this season of the year the movement of coal from New York is at a high level, owing to the heavy shipments going to shoal-water points, where navigation will soon be closed.

Contract movement is being seriously interfered with by the shortage of boats and slow transportation on the Sound, due to unfavorable weather conditions. These seem to be the worst for a number of years and at some points along the Sound where consumers have not stocked up liberally, shortages are being experienced.

Gas-coal slack has shown a decided improvement the past week. The unexpected early closing of Lake shipments caused a shortage sufficient to advance the price more than 25c. a ton over what slack was freely offered at two weeks ago.

The prices of steam grades in the New York market are considerably firmer, and quotations at which shippers are offering coal show an advance of from 5 to 10c. a ton.

Buffalo, N. Y.

There are a good many evidences of a livelier condition of the bituminous trade. Dealers complain of slow movement by rail and there are sometimes vexatious blockades at junction and transfer points. Certain railroads are accused of allowing distributing centers to choke up so cars cannot be handled and then reported they had not arrived.

The demand for slack is heavy and as soon as the lake trade is ended, so that the making of three-quarter is down to a winter basis the prospects are for fair price. It does not appear that much surplus slack intended for the lakes will be left over, though the heavy storm of the middle of November has cut down lake shipments.

There is a slight stiffening of bituminous prices, but figures remain at $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack. Allegheny Valley prices are about 25c. lower. Coke is without feature, prices being weak at $4.25 for Connellsville foundry and $3.50 for stock coke.

Lake shipments cease for the season this week. The amount loaded here for the past week was 87,000 tons. Shippers are anxious to keep up the movement as long as possible, for the Northwestern demand promises to be very heavy during the winter.

Pittsburg

Bituminous—Manufacturing and domestic demand for coal continues good, taking up a large part of the slack made by the close of the Lake shipping season, and operations are fairly heavy. Prices are about as well maintained as formerly, and we quote as the average market level: Nut, $1@1.05; mine-run, $1.05@1.10; ¾-in., $1.15@1.20; 1¼-in., $1.25@1.30; slack, 40@50c. per ton at mine, Pittsburg district.

Connellsville Coke—Contracting for furnace coke for next year has commenced, four or five contracts having been put through, but buyers and sellers are endeavoring to keep the terms reached secret. It is understood that the Rainey interest has taken the Youngstown Sheet and Tube Company's contract as usual, about 35,000 tons a month being involved, and that the price was a flat one, about $1.65. This interest is believed to have made at least one other contract, while others have made two or three. A market level has thus been disclosed for next year's furnace coke contracts, which may be quoted at $1.60@1.65 for the first half and at $1.65@1.80 for the whole year, the higher prices being for special favorites.

There is no general buying as yet, since the majority of consumers prefer to hold off, while among producers also there is conservatism. The common course among consumers will be to wait until near the close of December, and then contract only for the first six months. Furnaces which buy for the year at this time will do so chiefly because they wish to assure themselves a supply from among a few favorite brands. Of course, a large part of the

merchant business for next year is already covered by term contracts still having one, two or more years to run.

Sales of 3000 to 4000 tons of prompt furnace coke have been made in the past week at the regular price of $1.50. We quote the market as follows: Prompt furnace, $1.50@1.55; contracts, first half, $1.60@1.65; year, $1.65@1.80; prompt foundry, $1.80@1.90; contract, $2@2.25.

The *Courier* reports production in the week ended Nov. 18 at 316,379 tons, a decrease of 7000 tons, and shipments at 3546 cars to Pittsburg, 4960 cars to points West and 906 cars to points East, a total of 9412 cars, which is a decrease of 150.

Philadelphia, Pa.

There has been no diminution in the retail demand for anthracite coal in this market. The continuance of coal-burning weather is in a measure responsible for this, although there has not been any particularly low temperature as yet, but it has been threatening, and, as a consequence, the dealers are flooded with orders.

In the wholesale market, the verdict is almost unanimous that there has never been such a demand in the early winter season. Stocks of all sizes are being depleted, and the individual operators have no difficulty in disposing of all of their product, whether good, bad or indifferent. It is reported that some of the individual concerns are asking and receiving 10 to 15c. premium for their output of certain sizes, and there is some talk of the large companies advancing the prices. Apparently there is no disposition as yet for even a lull in the demand.

Baltimore, Md.

A canvass of many of the large offices of coal men brought to light the fact that there has been no important change in market conditions during the week. Spot business is about the same as the week previous, and the movement under existing contracts continues as usual.

Those who are buying now are getting coal at low figures. During the past few days, the low grades of coal have been quoted at 70c. per ton. In the office of one of the large coal companies it was stated that some coal had been sold as low as 60c. per ton, but not a large quantity could be purchased at such a price. For the better grades, the prices ranged between $1.30 and $1.60 per ton. Because of the absence of any undue activity in market conditions, operators say that the present price level will continue in force for some time to come.

Columbus, Ohio

Improvement has been reported in practically every branch of the coal trade in Ohio during the past week. The colder weather which prevailed over all of the State had the effect of strengthening the domestic and steam departments.

A car shortage has developed which has the effect of still further stiffening the market. It is the worst on the Toledo & Ohio Central and the Zanesville & Western, while the Hocking Valley is close up to the limit. A feature recently brought out is the practice of the Chesapeake & Ohio in using Hocking Valley cars in West Virginia territory. Shipments are delayed from two days to almost a week.

The production from Ohio fields has been good despite the car shortage which curtailed outputs to a certain extent. In the Hocking Valley the production was about 85 per cent. capacity while in eastern Ohio it was about 80 per cent. In the Pomeroy Bend district the tonnage was large and the same is true of the Jackson and Cambridge fields.

Prices prevailing in Ohio are: Domestic lump in the Hocking valley, $1.50; domestic lump in Pomeroy Bend, $1.60@1.75; ¾-in., $1.35; nut, $1.15; mine-run in the Hocking valley, $1.05@1.15; mine-run in eastern Ohio, 95c.@$1.05; nut, pea and slack, 40@50c.; coarse slack, 35@45c.; fancy grades of domestic sizes, $1.75@2.25.

Cleveland, Ohio

The lake coal trade is in about the same shape as it has been for the past week. There are a large number of cargoes on the market and the tonnage is very scarce. With no boats in sight, the shippers are not bidding, but a few big carriers could be placed for the head of Lake Superior at 80 cents.

Shipments to retail coal yards and to manufacturing consumers increased slightly this week. Genuine winter weather appeared with a suddenness that has rarely been paralelled, the temperature dropping over 30 deg. in a few hours.

Cincinnati, Ohio

Local market conditions are much improved over three or even two weeks ago. The principal cause for this has been the weather, although credit is due the steadying influence of tightness in the car situation, particularly on the Chesapeake & Ohio and Norfolk & Western railroads. There has been increasing difficulty in getting a sufficient number and the desired type of cars on most of the roads in this territory for some time. On at least one road the situation has become acute within the last few days, and it has resulted in serious inconvenience to several of the operations.

This car shortage has resulted in considerable friction in several of the wholesale offices on account of the railroads' inability to furnish the buyer with the equipment ordered. The number of hopper cars, it would seem, has been increased more rapidly than have the facilities of country dealers for unloading that class of equipment.

The steam demand is increased sufficiently to justify the statement that there must be increased industrial activity. The increase is not large, nor is it confined to a limited territory, but is of such a character as to indicate that general business is improved over what it was some weeks ago. Of course it is natural that there should be some steam-coal increase because of the continued cold weather.

Louisville, Ky.

The local market remains firm, with good supplies and the demand continuing brisk. Prevailing low temperatures are responsible for the latter. Shipments from Pittsburg continue to arrive regularly and the same is true of Kentucky and Tennessee districts. The western Kentucky mines are working more regularly now than during the past month, due to the practical settlement of the Illinios Central strike trouble. One local dealer is advertising extensively a rate of $3.50 a ton, cash, for Pittsburg lump, on a 2000 lb. to the ton basis. The prevailing retail price, however, is $3.75 a ton for Pittsburg. Straight Creek is retailing at $4; Jellico coal, of the best grade, is bringing the same, and Wilton, $3.60.

Charleston, W. Va.

The closing of lake shipments has made a change in conditions in the Kanawha and New River districts, in that there has been a decrease in shipments. There has been a fairly good increase in domestic movement both east and west, but this has by no means made up for the loss caused by the discontinuance of the coal heretofore going to the lakes. This condition was predicted in these despatches and was not unexpected by the coal operators.

Reports from the Norfolk & Western territory state that conditions are good,

which is usual for that district. The increase there has been greater than in any other section of the State. The only temporary setback suffered in the Norfolk & Western territory was during a let-up at the United States Steel operations at Gary.

Memphis, Tenn.

The operators in western Kentucky have had several meetings, resulting in a decision to advance prices on domestic coal, beginning Dec. 1. These prices will be $1.50 for screened lump, $1.25 for nut, $1 for mine-run.

The mines located on the Illinois Central railroad are still in a bad way for equipment. They get few cars for loading, and occasionally the railroad takes the entire output of a day's run for its own use.

The retail prices for Memphis are: $4 for Kentucky lump coal, $4.25 for Alabama, $4.75 for Jellico, $5 for Piper or Cahaba, $3.50 for Kentucky nut and $4 for Illinois washed coal.

These are the highest prices Memphis has had during any portion of the winter.

Nashville, Tenn.

There has been little change in the coal situation in the West Kentucky fields, and the demand for domestic coal may be considered good, although it is a weather-market proposition entirely in this field.

On Dec. 1, the price of domestic lump coal will be raised by the operators to $1.50 per ton, which is a 25c. per ton advance over the prevailing price. A small increase will be asked also for the finer grades of coal.

Dealers in this section are still carrying a small stock and a bad spell of weather will find the majority of them with practically no coal in their yards.

There is a good deal of talk in this district relative to a strike on April 1, 1912, and the operators seem to think that this is inevitable.

Indianapolis

The coal market has shown some improvement but is not yet entirely satisfactory to the mine operators. The market has been stimulated by cold weather, but the movement of coal from the mines has been greatly delayed because of slow transportation.

Both operators and miners in the block-coal fields of Clay and Vigo counties are bitter in condemning the policy of the railroads, because of their inability to properly handle the coal. A revival in business has been experienced by the coal companies within the last last month, but owing to the scarcity of cars they have been able to fill only a comparatively small number of their orders.

Chicago

The general tone of the coal market is far better than it has been for several months. The demoralization which has affected smokeless mine-run coal for the past six months is past, and there has been a boost in price from $1 to $1.10 at the mines. This price is quoted everywhere.

Leading shippers are practically out of the market, so far as Southern Illinois and Hocking Valley coals are concerned. The demand for these grades has led to an overflow upon some of the cheaper classes of coal. The demand for anthracite is strong and Western and Eastern buyers are engaged in a vigorous contest to obtain what they can of this class of fuel. A marked improvement has been noted in the furnace- and foundry-coke market.

Coke—Prices asked for coke are: Connellsville, $4.50@4.65; Wise county, $4.50@4.65; byproduct egg and stove, $4.95; byproduct nut, $4.55@4.65; gas house, $4.85.

St. Louis, Mo.

There is practically no change in the local market, with the exception that the smaller sizes in raw and washed coals have gone up from 10c. on raw screenings to 25c. a ton on washed No. 1. The car shortage has practically brought about this condition in the high-grade market, and, again, there is an extraordinary demand for screenings and steam sizes from the Northwest.

Lack of motive power on the Frisco has retarded shipments somewhat during the past week, and the Iron Mountain and Illinois Central are working their mines about two days a week. It is likely that prices of all high-grade coals will advance to something like $2 in the next 10 or 15 days; especially will this be so on Franklin county lump and egg.

[1] Freight to St. Louis, 67c.

Minneapolis—St. Paul

The situation in the trade is unchanged, everybody enjoying a steady business. There has been fair sleighing for a week which has facilitated hauling and dealers have been able to keep up with orders.

The dock people have been more than busy filling orders, but have been able to meet the demands well. Stocks on the docks are heavy now at the close of navigation. Insurance expires Nov. 25, and the shipments of coal expected up after that date are only scattering cargoes.

The wholesale companies in the Twin Cities, handling all rail will show a fine month's business during November. Their mines are running every day and behind on orders. Some are much hampered by lack of cars at their mines.

For some reason or other, there seems to be an increased tonnage of smokeless coal for domestic use this season, and as a result a number of the docks are already running short on smokeless lump and egg. The Splint coals are also becoming popular, as well as those from the Kentucky-Tennesee fields.

Anthracite is quoted at: chestnut, $7.20; egg and stove, $6.95; grate, $6.70.

Gas-house coke is moving slowly at $4.65, St. Louis, and byproduct at $5.

Salt Lake City, Utah

There are just about ten orders on file for each car of coal mined by the Utah mines, and as the coal season does not really start until Dec. 1, the indications are that this proportion is liable to increase rather than diminish.

The coldest November weather in many years brought a demand from the outside towns which could not be denied if it were possible to supply it; but as the mines were already operating to their fullest extent with the limited car supply, the dealers received little satisfaction.

No more cars are in prospect and as operating is becoming more difficult as

the cold weather advances, the movements of those in service on the coal roads will become slower. Mines are still working about half time.

There has been no change in price, neither wholesale nor retail, on Utah coal.

Spokane, Wash.

There is no change in local prices, though the market is fairly active. The resumption of operations in the Crow's Nest mines means there will be sufficient supplies for all demands throughout the year, also that the smelting plants soon again will be running full blast.

Jay P. Graves, of Spokane, vice-president and general manager of the Granby Consolidated Mining, Smelting and Power Company, said that the furnaces at Grand Forks, B. C., will be blown in within three weeks, adding:

"It will take some time to get going again at full capacity; besides requiring an ample supply of fuel on hand, there will be difficulty in building up an adequate working force at the mines after such a long shutdown."

San Francisco

We have to record quite an increase in the sale of coal during the past week. Lower temperature has stimulated the retail trade. Domestic consumers are getting a foretaste of winter weather and are accordingly providing against the rainy days we are justified in expecting during the next four months.

There is a marked improvement in country business, as the effects of winter are felt sooner there. There is a brisk demand for carloads to the interior; such orders are not being filled with customary despatch, owing to the car shortage which still continues.

Shippers from Utah mines are particularly handicapped because of a lack of motive power by the railroads. As a consequence we are advised of an increase in price of 25c. and 50c. per ton, f.o.b. the mines at these points.

Altogether the situation looks good and is viewed by all parties to the trade as quite satisfactory. The wholesale prices, ex-bunker or at ship's side, are as follows, per short ton:

Wellington, clean	$8.00
Wellington, average	7.50
Australian, clean	8.00
Australian, average	7.50
Puget Sound, clean	6.50
Puget Sound, steam .... $5.00 and	5.50
Pennsylvania anthracite	15.00
Colorado anthracite	12.50
New Mexico anthracite	13.50
Anthracite briquets	10.00
Cumberland, smithing	12.50
Utah, Wyoming and New Mexico, clean (for domestic use only) .... $9.00 and	8.00

Production and Transportation Statistics

The Virginian Railway Company

Shipments over the Virginian Railway for the month of October amounted to 293,971 short tons.

Chesapeake & Ohio Railway

The following is a comparative statement of the coal and coke traffic over the Chesapeake & Ohio lines for the three months ending Sept. 30, 1911:

To	1911	Per Cent.	1910	Per Cent.

Total	1,788,982	1,947,412	16,728,617	17,061,371

Baltimore & Ohio Railroad Company

The coal and coke shipments over the lines of the Baltimore & Ohio Railroad Company for the month of October, 1911, and for the same month of the previous year, were as follows, in short tons:

	1910	1911
Coal	2,722,144	2,801,933
Coke	386.727	338,133
Total	3,108,871	3,140,066

Lehigh & Wilkes-Barre Coal Co.

The following is a comparative statement of shipments by this company for fiscal years ending June 30, 1910 and 1911:

	1910–11	1909–10
From company owned lands[1]	3,042,486	2,885,314
From company owned lands[2]	967,933	962,577
From leased lands[1]	1,104,545	994,789
From leased lands[2]	115,024	140,576
From washeries[1]	137,411	141,668
From washeries[2]	171,943	197,657
Total of all	5,539,345	5,322,583

[1] Coal shipped by company. [2] Coal shipped by tenants.

Coal Exports and Imports for 1910

The exports of coal from the United States during 1910, according to the United States Geological Survey, were 13,805,866 long tons, valued at $41,470,792. Of this quantity 3,021,627 long tons, valued at $14,785,387, was anthracite, and 10,784,239 long tons, valued at $26,685,405, was bituminous coal.

The imports of anthracite amounted in 1910 to only 8,195 long tons, valued at $42,244, and those of bituminous coal to 1,497,709 long tons, valued at $3,975,561.

Lake Shipments from Toledo

Shipments for Hocking Valley docks to Nov. 24 of present year amounted to 2,298,065 tons, which is much larger than for the same period last year.

Foreign Markets

Great Britain

Tonnage arrivals are more satisfactory, but the market has not been materially affected meantime, and prices still show some irregularity for immediate loading. For backward shipment, however, sellers are holding for firm figures for both large and small. The labor situation is regarded more hopefully in view of the decision of the National Miners' Conference not to force a national strike. At present quotations are as follows:

Best Welsh steam coal	$4.08
Seconds	3.90
Thirds	3.63
Best dry coals	3.96
Best Monmouthshire	3.66@3.69
Seconds	3.48
Best Cardiff small steam coal	1.92@1.98
Seconds	1.80@1.86

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½ per cent.

Nova Scotia

Exports of coal from Nova Scotia for the first 10 months of the present year were 4,436,907 long tons. During the same period last year the exports were 3,998,300 long tons, showing an increase for the present year of 438,607 long tons.

Russia

Coal production in the Donetz basin, the most important district in Russia, for seven months, ended July 30 was in metric tons: Anthracite, 1,528,835; bituminous, 9,403,641; total, 10,982,176 tons, an increase of 1,496,194 tons over last year.

COAL AGE

Vol. 1 NEW YORK, DECEMBER 16, 1911 No. 10

THE achievements of every century are summed up according to the personal viewpoint of each observer. The architect looks upon present massive structures of stone and steel as typifying the progress of the age. To the merchant, the modern store with its multitude of departments and thousands of employees housed under one roof, represents best the growth of industry and intelligence. The philosopher regards the mind of the period as the symbol of its grandeur.

However, to the coal operator, whether his view is distant or near, at an angle or direct, the *Zeitgeist* of the 20th century is its "clean-up" tendencies. A failure to realize this truth is the surest way to grease the rungs of the ladder that leads up to successful mining.

Some operators have not caught on to the "Spirit of the Times" and are still worrying along with non-condensing engines, cylindrical boilers, isolated and disconnected power stations, beehive ovens and mule haulage, even on main roads.

Like the "oldest inhabitant," who cannot see the necessity in street cars and electric lights, they are governed by the wisdom of yesterday. The veriest approach of the *Zeitgeist* backs them up against the wall of their self-contentment, from which position national legislation, supported by the army, can hardly dislodge them.

If you suggest to them that many advantages result from the use of telephones in mines, the reply is that perhaps they are all right to order meat from the butcher, but when it comes to sending messages underground, the speaking tube or bell signal down the shaft answers very well.

You mention that three-phase electric current may, in some cases, have numerous advantages, and are told that sparks and shocks at the commutator have not so far done much damage.

When the subject of timbering is discussed and you state that actual tests in European mines extending over a score of years, have shown that one set of creosoted timbers will last as long as three sets of untreated oak, the answer is that the mine will not last forever, and it costs money to provide a plant to treat props.

This same operator will tell you that "our mines are not deep enough to make the question of sanitation underground worth consideration; we have plenty of coal, so what does it matter if we lose a little tonnage and spoil a few acres of surface." Anthracite operators sowed that seed a few years ago and the product of their planting is going to be a harvest of trouble for all except the engineers paid to provide a remedy.

The man who will win in coal mining as in all else is the one alive to the *Zeitgeist*. If the "Tendency of the Times" is to "clean-up," then begin at once, and after you have burned half the useless papers in and on your desk, tear out your antiquated machinery, concentrate your plants and start intensive mining.

Cut your butt-headings off with faces every 2000 ft. at least, and clean out the coal. To secure speed in haulage, you can afford to grade and condition a few main butt-entries, but not 10 more like them.

Of course, you want to keep up the appearance of your product, but the coal that is tarnished will not look any brighter next month or next year. Neither will your dip coal, nor any other tonnage that is hard to get, be easier to mine in the future. There are always a hundred handy reasons for not doing the things we do not want to do, but seldom is there a valid excuse for leaving developed coal.

Do not let the *Zeitgeist* knock in vain, and do not try to work the new mines of today by the old methods of yesterday. Remember that every suggested improvement will be demonstrated to be Utopian. A hundred eminent scientists proved the steam engine impossible and it was shown conclusively that aviation was a mere dream.

If it was not for the Rip Van Winkles that surround us, even General Sherman's vocabulary would not furnish a word to properly describe present-day competition. Some men strive to be above their age, but most of us may well be satisfied to be above our competitors.

Method of Mining in Southern W. Va.

By J. J. Marshall*

The Gas Seam No. 2 at Page, Fayette County, W. Va., is divided by a layer of slate. Where this layer is thinner than 24 in., the two coal-splits are mined conjointly. New workings of this mine are operated on the retreating system.

The financial success or failure of a coal mine, which is the real issue at stake, is due directly to cause and effect and owing to the "intimate connection of its several parts," it is imperative that in judging any one phase we should also keep in mind all other interdependent factors. The matter may be divided into three parts: The nature of the problems presented for solution, the general plan selected as solving these problems, and, last but not least, the manner in which the general plan is interpreted and executed by the operating department. The effect is automatically registered on the cost sheet, which latter is only a true index of success or failure when considered as an average for a term of years. The percentage of recovery is also due to cause and effect, for, given certain conditions and certain methods of mining, the result is inevitable.

In the not far distant past, coal lands were cheap and plentiful; the amount of capital necessary to develop and operate a mine was small, and it is not surprising that the question of percentage of recovery was considered merely an abstract proposition. Now, however, conditions have changed in many respects. Coal lands are rapidly increasing in value. What was formerly considered as reserve territory has been bought up by large corporations, and either developed or held for further increase in value. The amount of capital necessary to develop and operate a mine has become proportionately greater, and the question of percentage of recovery is now one of practical value.

Geological Considerations

The coal beds of West Virginia lying immediately above the Raleigh sandstone are classified as the upper Pottsville or Kanawha measures. The first of these beds is known as the "Eagle" or "Clarion," the second as the "Powellton." This latter is worked locally on Armstrong Creek in Fayette County, but to my knowledge is mined nowhere else. At that point it is 40 ft. below the third member of the Kanawha measures known as the No. 2 Gas bed. This latter bed, together with the Eagle, are worked by the Loup Creek Colliery Company.

No. 2 Gas bed, was at on time erroneously correlated with the Lower Kittanning bed of the Pennsylvania series. Along its eastern escarpment it is frequently divided into two or more benches by slate bands varying in thickness from a few inches to 50 ft., but this splitting of the coal by slates, thick or thin, does not affect the aggregate coal thickness which invariably totals, about 9 ft. In many places the entire bed can be worked as one, but as a rule the benches must be worked separately. This bed, in common with all those of this district, thins down to the westward as it approaches the Ohio River syncline and changes its character both structurally and chemically. Generally it is marked by well defined face and butt cleats, which lie so that the face headings follow the direction of maximum rise. This fact is used to advantage in mining, all face headings getting the full benefit of grade and drainage, as I shall explain later on.

In traveling westward on the Chesapeake & Ohio Ry., the No. 2 Gas bed makes its first appearance in the vicinity of Hawks Nest, in the Gauley and Cotton Hill mountains, at an elevation of about 900 ft. above the river, and has been worked extensively at Ansted since 1873, where it is known locally as the "Ansted seam." This bed passes under the railway grade at East Bank, 27 miles to the west. Numerous rivers and small streams drain this region, and erosion has carved the

Fig. 1. Surface Plant and Inclined Plane, Loup Creek Colliery Co., Page, W. Va.

*Mining engineer, Loup Creek Colliery Co., Page, W. Va.

Note—Abstract of paper read before the West Virginia Coal Mining Institute, Fairmont, W. Va., Dec. 5, 1911.

once continuous beds of coal into irregular and fantastic escarpments. The resulting long and broken outcrop lines offer many difficult problems in both outside and inside haulage. These disadvantages are, however, somewhat mitigated by the absence of explosive gases, which have escaped by the outcropping edges and are rarely found in dangerous quantities under such conditions. The drainage problem is also much simplified.

The report of the chief mine inspector, John Laing, for the year ending June 30, 1910, shows that 31 corporations operating 65 mines in the No. 2 Gas bed produced 5,600,000 tons of coal. To do justice to the methods and results in such a large territory would be an imposition on both your time and good nature, so I will confine myself to the mining operations of the Loup Creek Colliery Co., in the No. 2 Gas bed, and I submit, herewith, a map showing the plan and progress made to date in this mine.

Outside Haulage at Page

The mountains, around Page, rise to a height of 2700 ft. above sea level, or 1700 ft. above Loup Creek. No. 2 Gas bed is 700 ft. above the creek and dips N. 22° W. at the average rate of 100 ft. to the mile. Thus the cover over the coal varies from only a few feet at the outcrop to a maximum of 1000 ft. at the center of the mountain, the summits being capped by the Black Flint ledge. Beginning at the lower tipple (see map), with an elevation of spur track 1100 ft. above tide, a rise of 420 ft. is overcome by means of a double-track incline 1100 ft. long. This brings us to the bench formed at the outcrop of the Eagle bed. Here is located the upper tipple and drumhouse, and to it is brought the coal from both the Eagle and No. 2 Gas beds.

The remaining rise to the latter bed is overcome by means of a tramroad, with minimum curves of 150 ft. radius and maximum grades of 2.8 per cent. As the tramroad rises toward the dip of the coal, some relative elevation is gained from this cause also, so that the road reaches No. 7 drift mouth, at an elevation 1716 ft. above tide, the distance from the upper tipple being 8300 ft. From No. 7 northward to No. 2, the tramroad follows the outcrop of the coal on grades varying from 1.50 to 0.25 per cent., and with a minimum radius of curvature of 100 feet.

Split in No. 2 Gas Seam

A glance at the map will show that the No. 2 Gas bed, in this locality, is made up of two benches which are separated by a slate of variable thickness. This dividing slate may be compared to a finely tapered wedge. Beginning with a thickness of 10 in. at No. 2, it gradually thickens until 30 in. is reached near the mouth of the face entry. From this point southward the increase is rapid until a maximum of about 40 in. is finally reached. Twenty-four inches has been found to be the economical limit beyond which it is not practicable to remove this slate.

Fig. 2. Characteristic Roof Fall after Rib Has Been Drawn

At first, No. 7 was thought to be the last entry where both benches could be mined simultaneously, but later on, it was found that the slate was thinner under the center of the mountain than at the outcrop, and consequently both benches were worked together in No. 8 left. The aggregate thickness of the two benches averages about 9 ft., the upper bench ranging in thickness from 4 ft. 6 in. to 5 ft. 6 in. of clean coal, and the lower bench from 3 ft. 6 in. to 4 ft. of clean coal. Where it is impossible to mine both benches together, the upper bench only has been taken, and the lower bench is left intact for separate working in the future. Hereafter I will describe the coal where both benches are taken as the "high coal," and the seam where only the upper bench is taken as the "upper coal."

Manner of Attacking Coal

From No. 7 northward to the point of the ridge, the mountain, being narrow, is developed by pairs of butt entries, each of which is an independent drift opening, and has been worked as such. From No. 7 entry southward, the mountain widens out to a maximum width of over 6000 ft., and is split by a pair of face entries from which butt entries are turned right and left. In the high coal the entries are driven 10 ft. wide and 110 ft. apart from center to center, the rooms are 400 ft. long, and the barrier pillars 100 ft. wide. In the upper coal the entries are driven 10 ft. wide and 70 ft. apart from center to center, with rooms 350 ft. long, and barrier pillars 60 ft. wide. All rooms are on 60-ft. centers, the interval covering a 25-ft. room and 35-ft. pillar. All crosscuts are driven as prescribed by law, and are from 10 to 14 ft. wide. Except for a few "Pneumelectric" punchers which have recently been obtained, the coal has been mined by pick work, the mining seam being in the middle of the upper bench.

Clearance Height of Headings 54 to 60 Inches

The track gage is 44 in., the outside tramroad being laid with 65-lb., the entries with 35-lb., and the rooms with 16-lb. steel rail of standard sections. All turnouts, and track details in general, are standardized and factory made, thus avoiding duplication of parts and unnecessary confusion and delay in making repairs or replacements. A height of 5 ft. over the rail is maintained in the face entry. In the butt entries that clearance height is reduced to 4½ ft. Loose slate is promptly taken down and, except where it is impossible to avoid its use, no timbering is allowed in haulways. Permanent haulways are brought to a grade wherever this is necessary, and all haulways are kept in a clean, dry, safe and serviceable condition, experience having shown that, even where trip movement is not considered, it is cheaper to maintain a haulway in this manner than to keep a dirty and unsafe haulway in passable condition. Slate and track cleanings, from narrow work, are loaded into the mine cars and sent to the slate dump.

The mine cars are built by, or the materials obtained from, the Watt Mining Car Wheel Co., and are of wooden construction. The following are the dimensions and descriptive details: Height over rail, 3 ft.; 3-belt flared top; 16-in. loose wheel; end brake; weight, 2600 lb.; average load, 2.6 gross tons of coal; patent spring bumpers. From the time the coal leaves the face, until it is dumped into the railroad car, the object has been to make gravity do the work, and only on secondary haulways are there any grades

against the load, and even these exceptions are unimportant.

MULES, MOTOR AND STEAM LOCOMOTIVES

Haulage on the outside tramroad is effected by means of 25-ton steam locomotives, of which there are on hand three, one built by the Baldwin Locomotive Works, and two by the H. K. Porter Co. One steam locomotive can, and has, returned 60 empties up the grade, which makes the capacity 156 gross tons per round trip from the main assembling point at No. 7. The time required for a round trip being 45 min., it can readily be seen that outside haulage is amply provided for.

Up to June, 1909, mules were used to gather the cars from the face and deliver them to the steam locomotive on the outside tramroad. During that month a 500-volt d.c. electric haulage system was installed and, except in the high coal from No. 7 to No. 3, the mules have been replaced by 5-ton Westinghouse and General Electric gathering motors. As it stands now, the former method is still in use from No. 7 to No. 3, but in the territory served by the face entry, the gathering motor delivers the cars to the double parting at the mouth of the butt entry. A 10-ton General Electric motor gathers from these double partings and delivers to the steam locomotive, which in the meantime, has gathered from the mule hauls and is back at the main assembling point near No. 7. I may add here that the 10-ton parting motor is the primary unit of a 20-ton tandem, the secondary unit of which can be added at any time.

From No. 7 the trip is dropped down grade to the upper tipple, where the mine cars are dumped on a Phillips automatic cross-over dump, capacity three cars per min. into the chute which holds 75 tons. From this chute the coal is run into 8-ton capacity monitors which descend and dump automatically into the chute at the lower tipple, the time required for this entire operation being from 1½ to 2 minutes.

DISTRIBUTION OF ELECTRIC CURRENT

Having followed the coal on its journey from the face to the railroad car, we will now trace the electric current as it makes its circuit. Four 150-hp. Erie City return-tubular boilers furnish steam to a 500-hp. Nordberg-Corliss engine, which is belt-connected to a lineshaft. The lineshaft is in turn belt-connected to two General Electric generators rated at 160 kw. and 250 volts which, being connected in series, give 550 volts at the switchboard. The power line, consisting of three No. 0000 copper wires transmits the current to the mouth of the face entry at 520 volts. From that point the current is transmitted to the motors, pumps, etc., by one No. 0000 grooved trolley wire. The return is made through the rail, both rails being bonded with cross bonds every 500 ft. All electric wiring and bonding is kept in a constant state of repair, one man and a boy being detailed to take care of its erection and maintenance.

DRAINAGE.

Drainage presents, on the whole, no serious problems, and in many instances can be made to take care of itself in the natural manner; for instance, Nos. 8, 9, 10 and 11 Right are, and will continue to be, entirely drained by the openings shown on the outcrop. I may add here that $50 covered the entire cost of making the two openings to the dip of No. 10 Right. Siphons are used to unwater such dips as cannot be drained by ditching, yet are within, say, 1500 ft. of an outside opening. Where neither of the above methods is practicable, electric pumps are installed, or, if merely a few gallons have accumulated at a working face, the water box is made to do duty. The pumping equipment consists of 3 Blackmer rotary pumps, geared to 5-hp. motors, with a capacity of 50 gal. per min., and one Curtis rotary pump geared to a 10-hp. motor, capacity 100 gal. per min. The general direction of advance being toward the rise, the new work is not in any danger of being hampered by water from the old work.

FIG. 3. SHOWING EXCELLENT CONDITION OF RIB DUE TO RELEASE OF PRESSURE AFTER ROOF FALLS HAD EXTENDED TO SURFACE

VENTILATION SYSTEMS.

There has been no indication of explosive gas. The dust problem, also, owing to the natural conditions in the mine, offers no serious cause for apprehension. Nevertheless, this question is not overlooked and by keeping the roadways clean, regulating the air current, and, when necessary, using water on dry places, the possibility of a dust explosion is made still less likely. Let us assume that an explosion, or some other catastrophe, should occur. A glance at the map will show that it would, generally speaking, be local in its effect and the survivors would have at hand numerous avenues of escape.

The entries from No. 7 to No. 3, inclusive, are ventilated by means of the ordinary basket-grate furnace and wooden stack. The area of cross-section being large, and the distance the air travels being short, this method has proved sufficient. During June, 1909, the furnace at the mouth of the face airway was replaced by a 60-in., double inlet, Sirocco fan which was guaranteed to deliver 100,000 cu.ft. of air per min. at a 2-in. water gage. This guarantee called for two 35-hp. motors, but only one was installed and it has not been found necessary to install the second one—the fan fulfilling all present requirements and delivering with ease 80,000 cu.ft. of air per min. The fan is installed to either force or exhaust, but so far only the exhaust method has been used. The speed of the motor is varied by means of a field control rheostat, which is an invaluable feature.

EXCESSIVE VENTILATION AVOIDED.

When moisture is being precipitated on the roof of the mine, or when an excess of moisture is being carried away in the outgoing air, the speed of the fan can be easily regulated to deliver, at the working face, only enough air to fulfill actual requirements. By applying "the rule of reason" we will see that, under these conditions, to supply to the miner more air than he actually requires is to unnecessarily increase the risk of his being killed by a slate fall or by a dust explosion. The numerous openings on the outcrop facilitate ventilation, as well as drainage and timber supply, and, by using them as intakes, the speed of the fresh-air currents is kept uniformly low.

The main return, with the aid of an auxiliary air-way from No. 10 Right

to No. 8 Right, is also well provided for. No. 8 Right is aired from the opening which shows just to the right of the fan. No. 10 and No. 11 Right are aired from an opening at No. 6 dip room on No. 10 airway. No. 10 Left, No. 11 Left, No. 13 Left, the face heading and No. 13 Right are aired from the opening at the head of No. 10 Left. No. 8 Left and No. 9 Left are aired from the face entry intake. The head of No. 7 is aired from the opening which is shown to the dip of that entry. In short, this part of the mine is aired from five different intakes. The stoppings, in the face entry, are built of brick or stone, and in the butt entries of plank. Brattice cloth is used wherever it is necessary to deflect the current up into the rooms.

Mining Methods and Results.

Prior to September, 1905, the entries from No. 7 to No. 2 inclusive had been driven in far enough to include the first break-circuit crosscut, and a few thousand tons of coal had been shipped. Sept. 1, 1905, is, however, taken as the date on which the mine was put into operation. The above-mentioned method made it possible to produce a large tonnage from the very first, in fact, the question of output has, within reasonable limits, been regulated by market or transportation conditions. I may add here that the Deepwater Ry., now the Virginia Ry., was then in course of construction and was not in position to furnish the necessary car supply until Sept. 1, 1905. Also, that until the early part of 1909, the road being then declared open for Eastern shipments, the only outlet, available to this mine, was via Deepwater (on the Kanawha River) and the Chesapeake & Ohio Railway.

You will note that, beginning with the ordinary method of driving rooms and drawing pillars on the advance, the mine is now in condition to work the butt entries on the retreating system. This reversal in general method has been accomplished without lessening the output or adding materially to the cost of production. It will be readily understood that, with such an irregular boundary, no cut-and-dried method could be followed, so the object has been to fit the method to the place.

All entries and rooms are driven on centers, the sights for which are put in with a transit. This is a hard and fast rule, and the straight lines drawn on the map represent actual conditions. The time and labor required to put up these sights is small, the miner can check up the course of his place in a few minutes, and the advantages gained are too numerous and too apparent to require enumeration. The pillars are drawn in steps, and Fig. 5 shows the details of the method used.

Roof and Floor of Mine.

The roof of the mine varies considerably in both action and composition. It is of blue slate, sand slate or sandstone

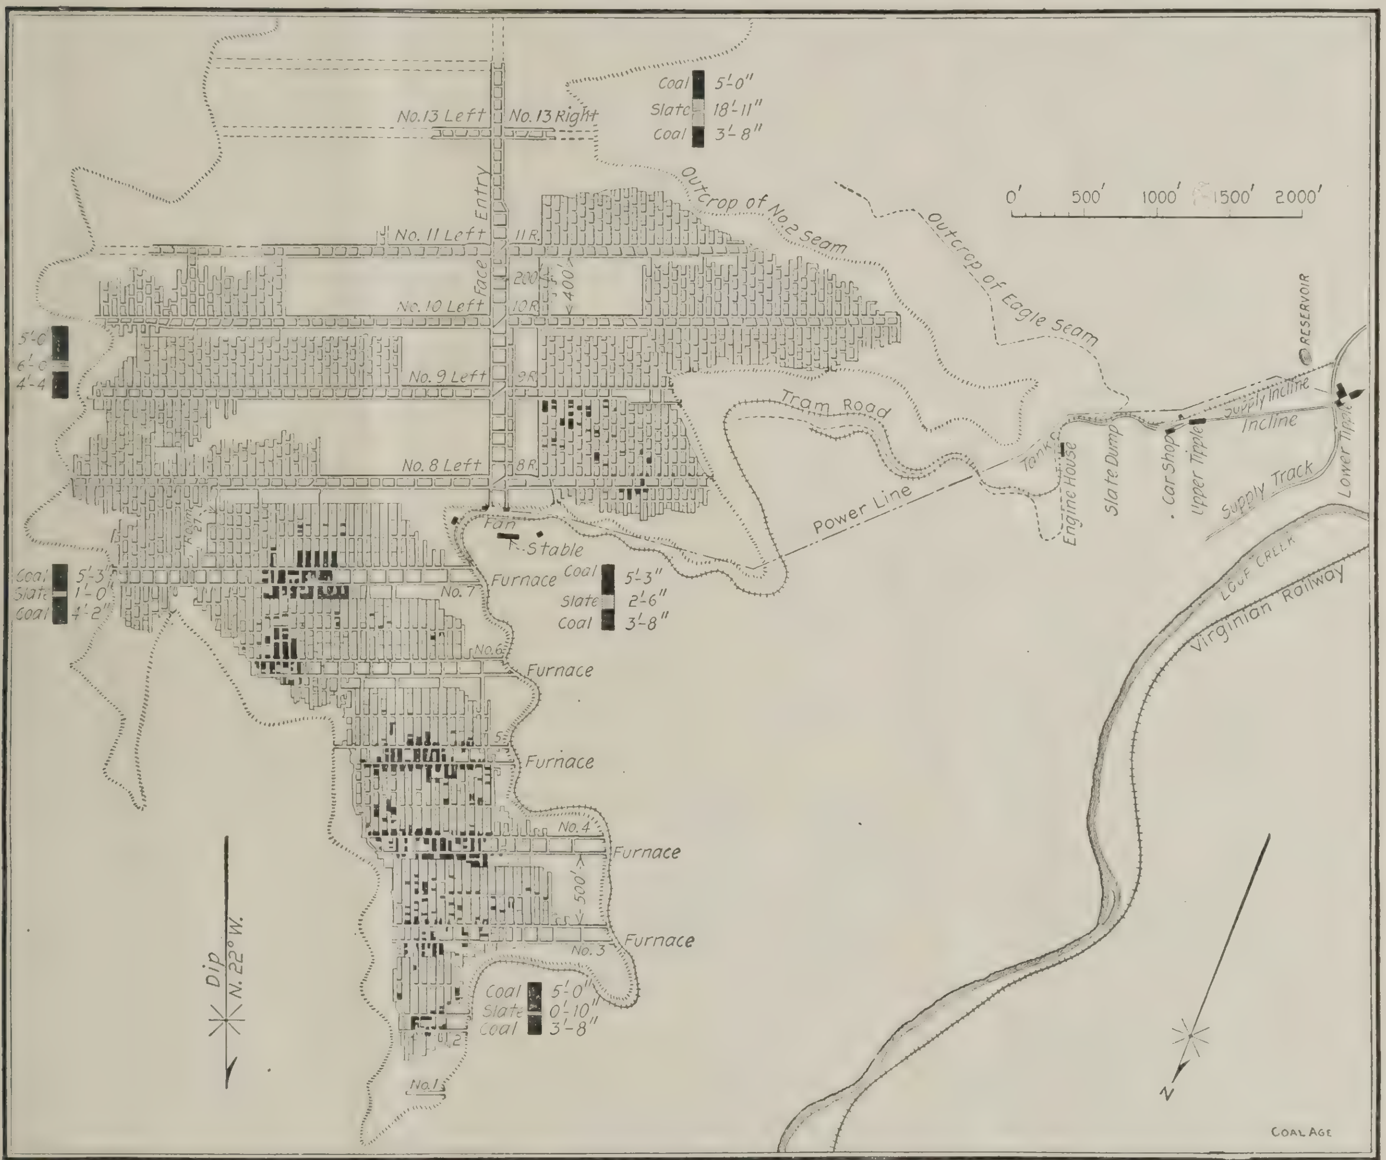

Fig. 4. Map of No. 2 Gas Mine, Loup Creek Colliery Co., Page, W. Va.

and slate mixed. It is usually stratified for a height of from 75 to 100 ft. Above this a massive sandstone ledge is reached, and this latter is hard to break.

In the high coal, the floor of the mine may be classed as good and consists of 8 in. of slate surmounted by sandstone. In the upper coal the floor, which is the previously mentioned dividing slate, is good in solid work and usually reliable in pillar work. In the latter case it has only given trouble when thin and in contact with water. Under such circumstances it may slake and creep. In the entries from No. 7 to No. 2 inclusive the rooms were worked on the advance and were turned as soon as available. The general method of pillar drawing, in this section, has been to draw the room pillar to within 100 ft. of the entry on the advance, and then draw the barrier pillar, chain pillar and room stump on the retreat.

The general grade of No. 6 entry is nearly level, but there are several depressions which, due to the pillars being drawn to the rise, catch a considerable volume of water during the rainy season, and for this reason the retreat has been seriously interfered with.

Loss From Squeeze.

In April, 1910, the pillar drawing in No. 7 entry was advancing in strict accordance with the general method, and all indications were that the roof was breaking as soon as the coal was removed. During that month a squeeze came on and it was only by hard work that the entry, from room No. 12 to room No. 20, could be kept open. This made a change in method imperative, so room No. 27 was turned into a haulway, and the coal from beyond the affected area was hauled that way to No. 8 Left. An attempt was then made to start in the center of the affected area and to retreat in both directions, but it was found impossible to get enough open space to insure a good fall.

The men were all withdrawn and the roof allowed to settle until this past August, and by working only one place on each side, a good start has been made toward getting a fall that will break the top far enough up to relieve the pressure. The only reason I can assign as the cause of this trouble is, that the previously mentioned sandstone ledge had not been broken, or that the roof was subjected to strains about which we, at present, know practically nothing. This occurrence is a concrete example of the advisability of working on the retreating system, and had it not been for the outlet through No. 8 Left, the coal beyond the affected area would either have been lost or the profit therefrom eaten up by the cost of maintaining an outlet.

The face entry was started in July, 1906, and, together with the right and left butt entries, was advanced as fast as circumstances would permit. No rooms were turned in this section until June, 1909, and the object has been to draw the pillars on the retreating system. The pillars in No. 9 Right were drawn retreating and the line of retreat continued down into No. 8 Right. Thus in No. 9 entry a recovery of practically 100 per cent. was obtained.

When the line of retreat coincided with the center line of the overlying spur, a period of wet weather occurring at the same time, a creep caused the loss of coal shown at that point, but this was overcome and a normal recovery was again obtained. The pillars in No. 11 Right are being drawn both on the advance and the retreating system. Those to the dip of No. 10 Right are being drawn on the advance, though four have been left to protect the air intake and drainage outlet. But pillar work is just being started on the head of the entry and hereafter the pillars will be drawn on the retreating system.

No. 12 entry was not turned because it would have come on the top of a small anticlinal fold, and the territory which would have been served by it can be served just as well by rooms from No. 13 airway. Nos. 10 and 11 Left are extended so that both rooms and pillars can be worked on the retreating system. In No. 9 Left the pillars are being drawn, both right and left, on the retreating system. The pillars in the upper end of No. 7 and No. 8 Left will be drawn on the retreating system with No. 8 Left as an outlet for both.

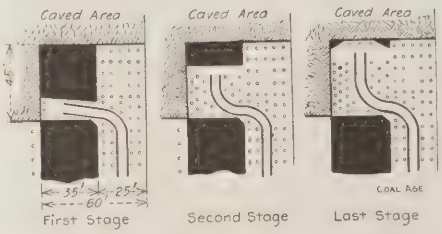

Fig. 5. Illustrating Method of Drawing Pillars

Success of Foregoing Methods.

Generally speaking, these methods have necessitated only a minimum amount of deadwork, of mine timber, and of track work and track materials. Also the large blocks of coal, which are at present left intact, should prevent the general extension of any trouble which may be brought about by the removal of pillar coal. In Fig. 3 is shown the condition of the rib of No. 10 Right airway between the face entry and the first room to the dip. This excellent condition is attributed to the fact that the entire removal of coal in No. 9 Right caused the roof falls to extend to the surface, 500 ft. above, and thus relieved the pressure.

In cost of production, the aim has been to secure a *minimum average*, rather than to let each month stand for itself alone. The cost of labor and material per gross ton of coal mined, was less for the year 1910 than for the year 1906, and for the five inclusive years the difference between maximum and minimum was less than three cents.

On June 30, 1911, the percentage of recovery stood as follows:

PERCENTAGE RECOVERY OF COAL

	Total Area From Which the Coal Has Been Extracted, Acres	Total Area in Which the Coal Has Been Lost Acres	Total, Acres	Percentage of Recovery
High coal (both benches)	77.75	6.86	84.61	91.8
Upper coal (upper bench only)	67.00	0.87	67.87	98.7
	144.75	7.73	152.48	94.9

Our Foreign Trade

British Correspondence

There is not much occasion for surprise in the report that several transatlantic lines are proposing to make use of American coal instead of British and other products. The reason for such a step is doubtless the same as that which has prompted the Egyptian State Ry. to ask for tenders for American fuel, namely, high prices and the fear of a widespread checking of supplies following upon a general strike in England. Already it is said, the White Star line has been coaling its vessels at New York taking aboard sufficient to last for the round trip.

Leaving the best Welsh out of the question as being in a class by itself, there is probably little difference between American coal and the high-grade British of similar description. In any case, if, as is alleged, supplies can be obtained at a substantially lower rate and without difficulty, steamship companies are acting wisely in developing a new source of supply. They learned a severe lesson at the time of the recent strikes at Liverpool and Southampton, and they are not likely to be caught napping should a national strike of the British miners take place.

Experience has shown that although moisture weakens some roofs it is usually alternate wetting and drying that does the greater part of the damage, especially where the roof is clay stone.

The Explosion at Briceville, Tenn.

Editorial Correspondence

This most recent disaster occurred in the Cross-Mountain mine No. 1, of the Knoxville Iron Co., and is thought to have killed 84 men. There is a disposition to regard the fireboss as negligent.

[*The following report was received by telegraph from a* COAL AGE *editor who is at Briceville making a personal investigation. Further details, with views of the ill-fated mine, will be published next week.*—EDITOR.]

A violent and disastrous explosion occurred at 7:20, the morning of Dec. 9, in the Cross Mountain mines of the Knoxville Iron Co., at Briceville, Tenn. It is thought that 84 men were killed. The bodies of 31 have been found. Five men were taken out alive, Monday night, Dec. 11.

The Cross Mountain mine No. 1 is located on a branch of the Southern R.R., four miles from Coal Creek, in Anderson County, Tenn. It is a drift mine developed along the room-and-pillar system, with butt-headings and airways right and left. The Coal Creek seam is mined, having a thickness of from 3 to 4½ ft. The bed lies about 35 ft. above Coal Creek at the drift mouth and at an elevation of 1006 ft. above sea level.

The coal is clean and shiny, and much dust collects on the roads. The mine is classified by the Tennessee State Mining Department as one which is dry and dusty to such an extent as to render it dangerous from dust explosions. State inspection is required every 60 days. The roads were occasionally watered, but no steam or water sprays were installed. Open lights were used. The coal was undercut by machines to some extent and also mined by hand pick. Black blasting powder was used for the coal and dynamite for the rock. Clay was supplied for tamping and its use ordered. No shot firers were employed.

The drift enters the mountain on an average grade of 1½ per cent. for 3100 ft. to a summit, and then descends on the same grade. No. 28 is the last butt-heading to have been turned off on the right and No. 26 the last on the left. The crossheadings are practically worked out as far as No. 15 Right and No. 17 Left which are the first headings still working. These headings, for the most part, are driven wide and the waste rock gobbed on one side.

Brick stoppings are used between the main face entry and its air-course, while the stoppings on the butt entries are mostly built of stone.

Electric-motor haulage is installed on the main entry for 6600 ft. The mine cars have no end-gates, but merely a latched crossbar, and the rear end of the car is low, both of which facts cause a great deal of coal to be dropped on the roads. Direct current of 250 volts was used for the motor haulage and also for driving the ventilating fan. The men push the cars in and out of the rooms and they are hauled by mules to a side-track in the main entry.

The Cross Mountain mine is said to have been worked for the past 20 years. No previous explosion of any consequence has been recorded, but gas has been found in small pockets, and has been lighted in bore holes. Sometimes dust has increased the force of these ignitions. In 1902 the neighboring Fraterville mine exploded, killing 200 men.

Ventilation was secured by means of a 7-ft. diam. Capell fan, rated to operate at 300 r.p.m. and installed at the foot of an airshaft, at the summit, 3100 ft. from the drift mouth. This fan was operated as an exhauster, the air entering at the drift mouth. It was driven by a 250-volt direct-current motor. The fan was destroyed by the force of the blast and the attendant killed.

It is claimed that the fireboss, J. F. Hatmaker, of Briceville, had recently inspected the mine and found no traces of gas. It is also said that the state mine inspector and the agent of a casualty insurance company had made a recent inspection. Rumor has it that Fireboss Frank Hatmaker may have been negligent in the performance of his duties.

The morning of Dec. 9 at Briceville was dry and warm. As stated, the explosion occurred about 7:20. Three men are reported to have been entering the mine at the time of the blast and to have escaped. It was several hours before organized rescue work could be attempted. A special train was sent out from Knoxville, in charge of T. I. Stephenson, president of the mining company, carrying members of the local mine-rescue corps with their rescue equipment.

In the mine, heavy falls of rock were encountered. The roof is of slate and bad for 4000 ft. from the mouth of the drift. Owing to roof falls, the headings here vary from 8 to 14 ft. in height and are heavily timbered. The timbers were disturbed clear up to the mouth of the drift and other evidences of the violence of the explosion were manifest. The gob from No. 23 Left was blown into the face entry, and the rails of the haulage road were bent. Attempts were made to restore ventilation by building a fire in the airshaft. Later a 10-ft. diameter blowing fan was secured from the Black Diamond mine and erected at an old opening to aid the rescue work. The air was forced along the passages where it had previously been pulled, but the direction of the usual current was not reversed. Brattices were built, but little progress could be made on account of the extensive cavings.

Sunday, the men were divided into gangs of 50 each, working a 2-hour shift. The débris was hauled by mules to the mouth of the drift and by 9 o'clock in the evening, after nearly 36 hours of continuous toil, the rescue parties had penetrated practically to the head of the main entry, and eight bodies had been removed to the surface. Of these, three were found sitting in a mine car and the balance discovered lying on the ground. All bore evidence of having been killed by gas, burning or by the violence of the explosion.

At daylight, Monday morning, efforts were directed toward penetrating the cross entries and a number of these were explored during the day. A second rescue car arrived, making three crews of helmet men on the scene. By night a total of 22 bodies had been taken out. At 11 o'clock, Monday night, five men were discovered alive in cross entry No. 19, seemingly little worse for their experience. Immediately after the explosion they had built themselves in with stone brattices. Two others, originally of the party, crept out and cannot now be found, although the indications are that they still live. The other five were able to walk to fresh air after being immured for 60 hours. One of the number was badly burned.

President Stephenson had all along maintained that many of the men would be found alive in their working places if they could but be reached in time. The discovery of the five living men, of course, lent renewed impetus to the work of the rescuers.

Mine-rescue cars from several sections of the country were immediately dispatched to Briceville as soon as word of the explosion had been received. Dr. J. A. Holmes and Messrs. Paul, Rutledge, Ryan and Burke are in charge of the rescue work. Every miner in the vicinity is reported to have offered his services. The local industry is practically suspended until the work of rescue shall have been completed. So far, 31 dead have been found, and 5 recovered alive; and it is estimated that between 50 and 60

are still entombed in the workings. The dead bodies all bear evidence of violence or burning.

The seat of the explosion has not yet been determined, but it is thought to lie on the left of the main entry. All indications seem to point to the fact that, however it may have originated, this was a dust explosion of great severity and strength.

Forestry for Mining Companies

Richard C. Eggleston*

The underlying idea of forestry is not *saving* but *use*—not alone present use, nor future use, but *continual* use. The object of forestry is to secure the closest, cheapest and most profitable utilization of the present forest products, and at the same time provide for a continual forest production. Hence, the forester regards and treats the forest as a growing crop, which must be cut when ripe and replaced when cut.

It cannot be argued that forestry would be a profitable investment to all private timber owners. However, with good markets, reasonable taxation and security from forest fires at a reasonable cost, a profit from forestry can be assured.

It is undoubtedly a function of the state to protect private and corporation owners of forest lands from fire, trespass and unreasonable taxation. But in most states, such encouragement, especially as regards the question of taxation, has been limited. Notwithstanding this condition of affairs, many private owners are making good profits by the practice of forestry.

Mining Forestry Encourages Use of Small Timber

Too much stress cannot be put on the importance of markets in the profitable practice of forestry. Good markets are the basis of intensive forestry; and coal-mining companies are particularly well situated in this matter; for they create markets not only for ordinary lumber, but for small forest products as well, such as room, mine and motor-track ties, mine props and poles. Hence, mining companies should be ardent advocates of forestry. It would be a good investment even for those whose dependence on a local timber supply was less binding. But mining companies are very intimately concerned with timber, if the enormous quantities used per annum have any significance.

Concerning the question of waste, Mr. Zon, of the United States Forest Service, says:

"In logging for mining timbers under present methods fully 40 per cent. of the timber handled is wasted. The chief items of waste are high stumps, tops, partially used bolts and even whole trees which are felled and rejected because slightly twisted in grain. The greatest mining demand upon the forest is for props, which are 3 or 4 in. square and from 4 to 9 ft. in length. Another large demand is for tram ties. Under such conditions clean logging and the fullest utilization of the tops down to a diameter of 4 in. should present no difficulty if proper supervision is given to logging operations. To secure a close utilization of timber it would be best to saw into the required sizes the rougher material from the tops as well as the entire stems of those species which are difficult to split, instead of following the present practice of splitting the timber into props and rejecting all logs that will not split readily. If mining timber is cut into bolts of the required lengths in the woods, it can be sawed at the mines to the required sizes at a great saving over the present wasteful methods of manufacture by splitting."

Mining companies are dependent on the local timber supply and the time is not far distant when the adoption of a sound forest policy will become a necessity. Already forestry has found a place in railroad management, and railroad companies with their hard economics are not much given to fads.

Correct Forestry Principles

A forest policy for mining companies should be developed along the following general lines:

(1) Protection from fire.

(2) Working the woods properly, so as to secure the greatest economy in the utilization of the timber.

(3) The employment of a trained forester for the organizing and supervising of the forest work.

In general, the system of fire protection will include: (a) the rigid enforcement of the fire and stock laws of the region and the securing of the state's coöperation, both in the matter of taxation and fire patrol; (b) the education of the local public as to the damage done to the community by fires, and the securing of their good will; (c) the establishing of an efficient fire patrol during the dry season; and (d) the piling and burning of brush when the weather conditions are suitable.

In order to have the woods worked properly, the following rules should be enforced:

(1) Stumps should not be higher than 18 in., and lower when possible.

(2) All felling should be done with the saw.

(3) All merchantable material in the tops down to a diameter of 4 in. should be utilized. Smaller material should be used if possible.

(4) All cut or fallen trees should be prepared for use.

(5) No bolts should be left in the woods.

(6) When possible, trees should be felled up-hill, thus lessening the danger of breaking.

The services of a trained forester are needed, temporarily or permanently, depending upon the duration of the forest work to be performed. He is needed not merely to supervise the cutting and disposition of the timber, but also in silviculture, which is the art of establishing, developing and reproducing forests. For in developing a forest policy, the selection of the correct system of silviculture to be used is a factor of great importance.

*Forester, Consolidation Coal Co., Jenkins, Ky.

NOTE—Abstract of paper read before the West Virginia Coal Mining Institute, Fairmount, W. Va., Dec. 5, 1911.

Tamping Explosive Charges

Special Correspondence

Thomas Johnson, of Dudley, Worcester, England, has introduced a new device for tamping or stemming explosive charges. The form of the device is that of a cylindrical plug made of an argillaceous composition and of an identical shape with the familiar charge of compressed gunpowder. The first plug to be introduced into the hole following the charge, called the "primer" plug, is immersed in water for a few seconds. Its nature is so readily absorbent, and several perforations running through its entire length render such assistance as to cause it to take up almost half its weight of moisture without any exudation whatever; from this fact it is obvious that a quantity of moisture introduced on the top of a charge must considerably minimize the danger in gaseous mines.

In a personal communication, the inventor says that if the plugs are properly stemmed with a copper-ended rammer, a blownout shot is impossible, the stemming becoming as hard as the coal it is intended to blast. As time savers, the plugs are a great asset, a hole being stemmed in less than one-tenth the time usually taken. No detonator wires can be cut or damaged as the material is of a smooth or velvety nature. It is added that as much as 33⅓ per cent. of explosive has been saved by their use, and it follows that through the stemming being vastly superior to clay and other similar materials, the efficiency of the explosive is greatly increased.

An Actual Test

In the description of an experiment at the Oxcroft colliery belonging to Mr. Markham, M. P. for Mansfield, England, it is stated that the first hole in the coal was 4 ft. 6 in. deep, charged with Bob-

binite. This was tamped with a damp primer and five dry plugs. The shot was fired, and on returning, the managers expressed themselves well satisfied with the report, which was instantaneous.

In the next hole, overlying the coal charged with Bobbinite, four solids and one primer were used, and the shot did its work equal to the first shot. Then it was suggested that only three solids should be used in a 4 ft. 6 in. hole in the coal, and after discussion is was decided to use only three solids 2¼ in. in length, that is 6¾ in. of tamping in a 4 ft. 6 in. hole. When this was done, the plugs resisted being blown out and held the explosive charge well up to its work, with the result that much bigger coal was got than with the old methods of tamping.

Somewhat similar experiments, with equally favorable results, were conducted at the Cannock & Rugeley company's chief pit. The shots were fired by electricity, and on returning it was found that the explosive and tamping had brought down excellent lumps of coal, thereby saving 25 per cent. In the third shot hole, 4 ft. deep, they charged up with 2¼-lb. cartridges instead of 3-lb., and tamped with four plugs. This was a saving of 33 per cent. in explosive, and the work was well done, the coal being got in massive lamps. "The experiments in the Cannock deep hard coal," it is added "clearly prove once and for all that with these plugs, the holes can be tamped in a half a minute—25 per cent. saving in explosives and bigger coal the result."

A Personal Opinion

In a communication in which he says his opinion generally of these plugs is high, and that their use is worthy of recommendation, Mr. Blunt, manager of the Oxcroft colliery, gives his reasons as follows:

(1) If these plugs are used it prevents the careless use of coal or dust.

(2) The cartridge-like form of the plug and the material from which it is made renders the aid of stemming a shot-hole easy, and at the same time perfect.

(3) No damage can be done to the wires of the detonators owing to the plug being free from any hard substance, thus preventing misfires; the cutting of the detonator wires is the most common cause of missed shots.

(4) Blownout shots will be prevented as the shot-hole will not be the line of least resistance. The dampening of the primer plug with water no doubt causes the plug to swell, and backed up with the solid plugs renders the shot-hole solid.

In the case of shot-holes being bored into a break in the coal or stone, as the case may be, these plugs can be fixed into the hole before the explosive, and they will no doubt thoroughly fill up such break. If such breaks or cracks should contain gas, the possibility of lighting the gas is rendered less liable. The length of stemming in the hole on the explosive can easily be known, as the shotfirer can count the number of plugs placed in, thus the danger of any hole not having sufficient length of stemming can be prevented.

(5) The efficiency of the explosive in doing its work is increased, because the primer plug removes all air bubbles from the shot-hole, and the heat generated by the explosive when fired causes a greater expansion of gases.

(6) Time is saved in firing the shots. The deputy or shotfirer who may have a good number of shots to fire on his rounds, knows that the stemming is ready and needs no examination for coal or coal-dust. The shot-hole can be stemmed in less than half the time that is consumed with the ordinary self-made pellets of clay.

Kentucky Mining Institute Meeting

The attendance was not large, owing to the inauguration of the governor and the fact that the mines are working full time. A number of interesting papers were read.

The winter meeting of the Kentucky Mining Institute, held in the College of Mines Building, of the Kentucky State University, in Lexington, Dec. 11, presented an unusual anomaly, a scanty attendance being coupled with papers of more than ordinary interest and value.

B. R. Hutchcroft, mining engineer, the appointee of the executive committee, in place of John Bond Atkinson, deceased, opened the meeting at 2 p.m. The appointed president of the meeting spoke with much evident feeling regarding the loss sustained by the institute in the death of Mr. Atkinson, whose sterling qualities had endeared him to all mining men in Kentucky.

The paper by C. R. Conner and W. H. Cunningham was the first read. Mr. Cunningham carried his arm in a sling as a result of a recent railway accident. His paper on "Boreholes for the Relieving of Accumulations of Gas" will be published at length in a following issue of this paper, together with the remarks of Prof. C. J. Norwood, which followed as discussion.

Other papers read were by J. E. Butler, superintendent of the Stearns Coal & Lumber Co., of Stearns, Ky., and Mr. Woodward, of the Carnegie Steel Co., who presented a paper on "Steel Mine Timbering"; both of these papers will be published in a later issue of Coal Age.

R. D. Quickel, of the fuel department of the Queen & Crescent R.R., read a paper on "A Few Factors Entering into the Purchase of Coal for Locomotives." One interesting point in this latter discourse was to the effect that the department of which Mr. Quickel is chief had found that 5-in. lump coal had 33½ per cent. greater efficiency than 2-in. lump.

F. J. Fohs read a paper on the "Importance of Statistics," in which he pointed out that statistics were prepared for no one more especially than the operator, and that mining men should assist more readily in their collection, and endeavor to make the statements of the statistician as correct as possible. This paper had but little reference to coal mining, and it is, therefore, not reproduced.

Prof. Norwood, who, as chief mine inspector of Kentucky, collects all the statistics of the mining industry, drew attention to the fact that though the state had a low fatality rating, and though the mines were as safe as any, the underwriters assessed the operators in Kentucky more for liability insurance than the operators in any state of the Union. Two insurance companies had refused to accept risks of that nature in the state. He said that operators returned all accidents, however small, without giving sufficient details to show whether they were serious or not. Some operators marked all accidents as not serious, and he was obliged to change their reports, knowing this defect; he added further that he was at a loss sometimes as to what changes to make, because they did not sufficiently indicate the nature of the injuries their operatives had suffered. He advised more careful reporting of accidents to the end that the underwriting of operations in the state might be made less burdensome to the operators.

H. H. Small, of the Goodman Manufacturing Co., then delivered an *ex tempore* address on mining conditions as he had found them in Europe.

The attendance at the meeting was much affected by the coming inauguration of the governor, at Frankfort, the following day; moreover, the mines are now working full time and the members found it hard to leave their mines.

The treasurer, M. L. Conley, was unable to be present, being at the hospital undergoing treatment for typhoid fever.

An Anthracite Plant, Hazleton, Penn.

Special Correspondence

The Andenried breaker of the Lehigh and Wilkes-Barre Coal Company is a successful modern installation of 1500 tons daily capacity. The method of preparation is typical of the Lehigh region.

The Audenried colliery of the Lehigh & Wilkes-Barre Coal Company is located at the town of that name, about 3½ miles from Hazleton, Penn. The operation is an old one, dating back some 40 or 50 years. The breaker erected in 1870, after good service for over 30 years, was destroyed by fire in 1904 and the present thoroughly modern plant was subsequently built. This has satisfactorily handled a daily output of 1500 tons, during the past four or five years.

A photograph showing the breaker and surroundings is given on the front cover of this issue. The structure, as will be noticed, is rectangular, compact and self-contained, unlike many of the older and frequently remodeled buildings in the vicinity. It is of timber construction throughout, with concrete foundations and a concrete floor under the loading pockets. Coal is brought to it from the mines by a slope rising on the side of the building opposite to that shown in the photograph. The hoisting-engine house for this slope may be seen in the foreground of the picture.

In this region, the eastern middle anthracite field, the coal is obtained almost entirely by pitch mining and a considerable amount of rock is necessarily brought out with it. Large quantities of water accumulate in the steeply pitching workings and most of the coal is wet as it comes from the mines. This fact makes it necessary to wash practically all the coal as it passes through the breaker in order to remove the fine material which adheres to the surface of the lumps. There is little or no dry preparation and incidentally the whole scheme is simplified on this account. The plan of preparation at the Audenried plant is shown in Fig. 1. A distinctive feature is the separation of flat coal from the balance of the stream as it leaves the screens and the treatment of this flat coal by means of spiral pickers.

Following the course of the coal through the breaker, it is seen to be first discharged from the dump chute onto a set of oscillating bars which remove the lump coal and allow steamboat and smaller to pass through to a hopper beneath. The lump coal passes from these bars to a moving picking band and here rock is removed from it by hand. It is then crushed and led to a revolving screen which takes off steamboat size. The oversize from this screen is passed through a set of No. 2 rolls and rejoins the undersize on its way to a double revolving screen which makes broken and egg size coal. The small coal from this screen is led below to two sets of shaking screens which make stove, nut and pea sizes. After careful examination, all sizes from broken to pea coal, are passed

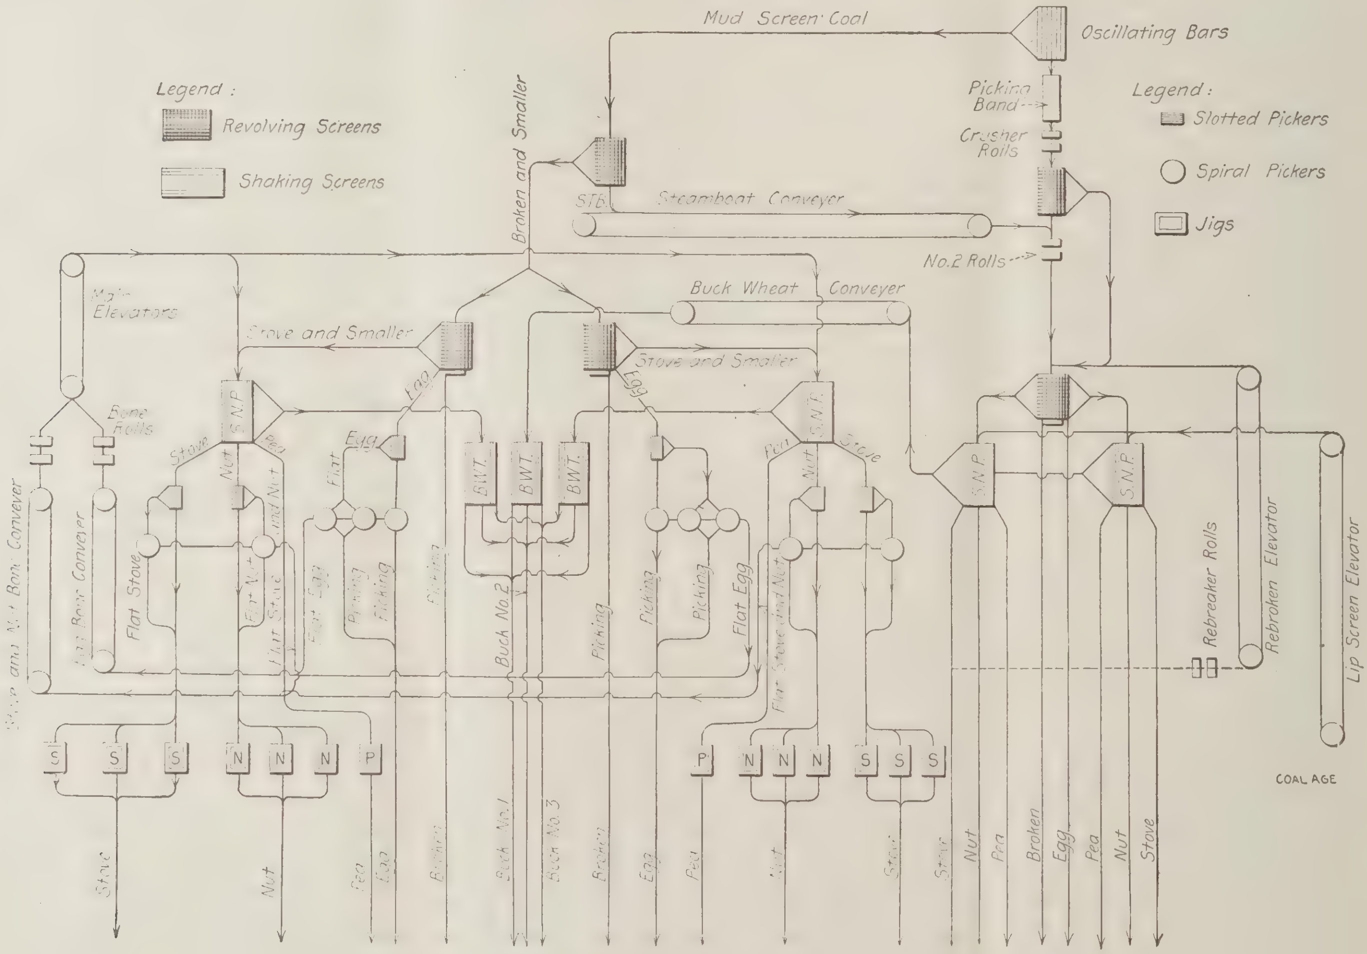

Fig. 1. Diagram of Preparation, Audenried Breaker

directly to the pocket. The fine coal passing through the pea-coal shaker, is conveyed to a set of buckwheat screens at the rear of the breaker, which makes three sizes of buckwheat; Nos. 1, 2 and 3.

Following next the mud-screen coal, which passes through the oscillating bars, this is led first into a revolving screen that takes off steamboat size, which is examined and then conveyed to the No. 2 rolls, mentioned before. The undersize from this screen divides and passes to two double revolving screens which make a separation of broken and egg coal. The broken coal formed here is hand picked and passed directly to the pockets; the egg coal is mechanically divided into flat and round material. The former portion is passed over two sets of spiral pickers, the latter over one picker. The cleaned egg coal is examined and sent to the pockets; the boney coal is collected and sent to the boney-coal conveyers.

Handling the Undersize

The undersize from each of the double revolving screens is led away to two sets of stove-, nut- and pea-coal shakers. The stove and nut coal from these screens is divided just as is the egg coal; that is, flat material is mechanically removed and passed over two sets of spiral pickers. The balance of the stream goes to the jigs. There are in all 14 jigs; six stove-, six nut- and two pea-coal jigs.

The undersize from the last mentioned batteries of shaking screens passes to two sets of shakers which make the three buckwheat sizes. Buckwheat coal is not jigged. The boney-coal refuse from the mechanical pickers is conveyed to rebreaking rolls where it is crushed; it then passes to the main elevator and is thus returned to the mud-coal stream for repreparation.

Provision is made for breaking down the larger sizes of coal and subsequently re-sizing same. There are two loading tracks and the usual elevator for lip screenings and condemned coal. An admirable feature of this plant is the rock pocket of ample capacity which extends across the full width of the breaker and discharges as required into rock cars, which are handled by small steam locomotives. The concrete floor already referred to as paving the space beneath the loading pockets is self draining and aids greatly in keeping this portion of the plant in a cleanly and presentable condition. The breaker is steam-heated throughout. This colliery is one of ten owned and operated by the Lehigh-Wilkes-Barre Coal Company in the Wyoming and Lehigh districts of the anthracite coalfield. C. F. Huber is vice-president and general manager.

Coaling Stations at Panama

A recent consular trade report states that the bunkering and equipping of the world's transportation lines which are expected to pass through the Panama canal should involve an immense sale for American fuel and ship stores. In this connection, the report goes on to say, the following interesting recommendation is made by Col. George W. Goethals, chairman and chief engineer of the Isthmian Canal Commission:

"The revenues of the canal should go to pay not only the operating expenses, but to repay the capital invested. Every legitimate means for increasing revenue should therefore be adopted. The Government should have coal and fuel oil on hand for its own vessels, and these commodities should be sold to other shipping which uses the canal. These should be supplied at an established rate and purchased after advertisment."

Coaling and Docking Facilities

"As the act of June 28, 1902, contemplates the construction of terminals for the canal, any addition to the docks should be such as to form a part of the final scheme, which should also include coaling facilities and a dry dock as necessary adjuncts to the canal. These facilities were to include the storing and furnishing of coal and other fuel for use both afloat and ashore. A coaling station is contemplated at each end of the canal and an arrangement of docks which will permit subsequent additions."

As the opening of the Panama canal to commerce is now expected to be as early as 1914, it would be well to look forward to prospects for the sale of coal and ship chandlery from the United States. The coal bunkering of vessels should develop into enormous proportions, as the canal will be the "halfway house" between the East and the West, and its location indicates that it should become the greatest coaling depot in the world. Some idea of the amount that will be needed at Panama may be gained from the fact that the coal bunkering at the Canaries now amounts to about $5,000,000 worth annually. England's coal exports aggregate about $200,000,000 a year, much of which is for coaling vessels in foreign parts, while in addition 2,000,000 tons are "shipped for the use of British steamers engaged in the foreign trade." It would not be too much to expect an annual coal and oil traffic of $10,000,000 to develop at Panama.

The Isthmian Canal Commission advises the Bureau of Manufactures that "if the supply depots are established it is thought that the supplies for same will probably be purchased in the same manner as supplies used in the construction of the canal are now secured, namely, by advertising for proposals, which method gives everyone an opportunity to bid.

Pacific Coal Industry and the Canal

Looking into the future, coal dealers are wondering what effect the opening of the Panama canal will have upon the coal trade here. It is believed it will depend largely upon what inducements are given American vessels to enter the coastwise trade, a question now being vigorously agitated in the press of the country. Owing to the expense of getting coal from the large fields, steamships in the coastwise trade are nearly all burning oil, and river steamers discarded wood and coal for oil several years ago. Low transportation charges through the canal, it is pointed out, may result in a return to coal.

A number of European steamship companies are turning their eyes on the Pacific coast with a view to establishing regular steamship lines between ports on the coast and Europe. With them fuel is an important question, and they are now seeking information on what may be expected along that line.

Portland is preparing for the increased steamship traffic that it is believed will follow the opening of the canal by building municipal docks equipped with the most modern coal bunkers and apparatus for coaling vessels, and the question where the coal is to come from is, therefore, a matter of conjecture. At present vessels for off-shore destinations usually take on enough coal here to carry them to Comox, B. C., to fill their bunkers.

Overwinding

Messrs. Pickering and Poole, in their paper on contrivances designed to prevent overwinding, presented the following conclusions for the discussion of the members of the British Institution of Mining Engineers:

(1) That the provision of automatic controllers makes enginemen more attentive and prevents slovenly and irregular winding.

(2) That the provision of automatic controllers, detaching hooks and similar appliances will prevent many accidents from overwinding and some from breakage of ropes and cage attachments.

(3) That it is desirable that all large winding engines should be fitted with such controllers.

(4) That detaching hooks are necessary, except in cases where the shafts are shallow and the winding speed slow.

(5) That at large, modern collieries, additional "keeps" should be fixed in the pit frames.

(6) That in many instances movable junctions might with advantage be fixed at the landings.

(7) That a revised method of determining the breaking strain of detaching hooks is desirable.

Gravity Planes with Monitors

Special Correspondence

Describes a system of gravity-plane haulage using monitors or gunboats. These planes are often highly inclined, causing an excessive waste of coal when using the ordinary mine car, which is avoided by the use of monitors.

The monitor system is a method of lowering coal, ores, etc., which has been in use for quite a number of years in some sections, but has never been introduced in the majority of mining communities. It, of course, has its drawbacks and its advantages but its good points are believed to be so far superior to its weak ones that only the former will be considered.

The monitor system, which is applicable on all grades of 5 per cent. and over, consists of a lowering device (either drums or sheaves, preferably the latter), two large wood or steel cars, termed monitors, of from 5 to 20 tons capacity, an adequate rope and the necessary rollers and track suitably arranged. All of the above, with the exception of the track arrangement and the monitor cars, are so well known that they need no description in this article.

The Monitor Car

The monitor car of the present time is usually of steel and has a large capacity. It has various shapes and sizes and many different means of operation. The most common form of monitor car is the cylindrical type, the diameter of which is usually fixed by the gage of track and outside conditions in general. This type of car is used where the grade is fairly heavy, and it is built up of a number of steel rings, usually 4 to 5 ft. in width, firmly riveted together.

The front or lower end of the cylindrical car is closed, the top half being riveted to the cylinder or body of the car, as shown in Fig. 1. The bottom half, or the door, is hinged to the top half, and the door fits into a chute, or what is commonly known as a "hog-snout." This chute is usually lap jointed to the body of the car.

The door is held closed by means of a latch or hook on either side of the chute, into which fits the locking bar. This in turn is fulcrumed at the center by means of a bolt, which runs through the center of the door. The locking bar is weighted at one end so as to insure the door locking each time the car starts up the hill, as will be explained in detail later. This bar is also held in place by a number of guards which prevents it falling or rising out of the required position. The bottom of the back or top end of the car is closed usually half the diameter of the cylinder, as shown in Fig. 2. The top of the rear end of the monitor is open and is provided with perpendicular sides, by means of which the material to be transported is directed into the car.

The illustrations, Figs. 1, 2 and 4, show a monitor which is capable of handling 6 tons of coal. The coal in this case is dumped directly from the mine cars into the monitor which is dropped to the bottom of the plane when loaded.

The illustration Fig. 2 shows the car dumping. It will be seen that the rear axle of the car is provided with four wheels. The larger two, or the inside ones, operate on the track of the plane, while the outer or smaller wheels operate only on the dumping track at the tipple. This dumping track begins about 35 or 40 ft. back from where the car dumps into the railroad car, or bin, as the case may be. It will be noticed by reference to this figure that the outer track takes a uniform rise above the grade of the tipple. The object of this is to elevate the rear end of the monitor so the coal will slide out freely when the door is opened.

Fig. 1. View of Dumping End

Fig. 2. Showing Monitor While Dumping

Method of Working

Referring again to illustration Fig. 1, which shows the latch bar and the two catches, it will be noticed that the latch bar works upward from one catch and downward from the other. It will also be seen that the latch bar extends about a foot over each side of the car. While

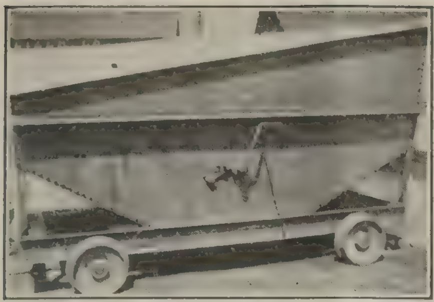

FIG. 3. BOTTOM DUMP MONITOR

the car is being elevated to its proper dumping position, as shown in the illustration Fig. 2, the ends of the latch bar are sliding upon two trip rails, one on each side. These rails are so arranged, in this case, as to depress the left end of the bar and raise the right, thus disengaging it from the latches and allowing the weight of the coal to force the door open ready for dumping.

When the car starts up the plane, and the rear end has again been lowered off the elevating track, the door automatically closes by its own weight, the chute and the latches being set far enough out of the perpendicular to insure the locking bar entering the latches and closing the door.

This type of monitor door is especially recommended, as it is purely automatic, the only attendant necessary on the lower tipple being the car shifter. Owing to the fact that the door opens and closes itself, the only laborer needed on the upper tipple is the man who dumps from the mine car into the monitor.

It is essential in installing a monitor system having this type of door, that the trip rail will have opened the door of the monitor just before the small wheels have reached the topmost point in the elevated track. Otherwise, the weight of the coal, combined with the slight jerk in bringing the cars to a stop, by applying the brakes of the lowering device, will cause the door to spring outward and spring the locking bar. This will cause leakage of the coal as the loaded cars come down the plane.

By referring again to illustration Fig. 2, it will be seen that this car is provided with three drawbars, one of which is on either side, attached to the one-inch chain. The third drawbar is on the bottom of the car, and is connected to the end of the rope. There is no strain on the rope between the clamp and the draw bar, this being merely in the nature of a safety attachment.

On some planes, where the grade on the bottom tipple will give the car sufficient pitch to assure the coal sliding out when the door is opened, the elevated tracks and the second set of wheels for such plane, can be eliminated. Or in some cases, they can be eliminated by making an abrupt change of grade at the point of dumping; however, this is not

FIG. 4. VIEW OF TIPPLE, SHOWING MONITOR DUMPING

FIG. 5. LOOKING UP PLANE AND SHOWING PARTING

FIG. 6. LOOKING DOWN TOWARD THE TIPPLE

often satisfactory as it causes a jerking or flying of the rope, due to the sudden stop when the trip runner lands the car.

Illustration Fig. 6 is a view looking down the plane, just below the point of passing, showing the monitor car dumped and ready to ascend the hill. Fig. 5 is a view taken at the same point, but looking up the incline, and showing the track arrangement.

Illustration Fig. 4 is a side view of the bottom tipple, which shows the two sets of rails with the car in position to ascend the plane. On some planes, where the grade is light, it is advisable to use open monitors. Owing to the fact that it would be impossible to load the closed monitors at the top tipple, these open ones can be made with the same kind of door arrangement as above described.

Bottom-dump Monitors

Illustration Fig. 3 shows an open-type monitor with a drop-bottom. This monitor has a capacity of 6 tons and is in operation on the plane of the Clearfield Colliery Company, of Clearfield, Penn. It has two doors in the middle of the hopper, which are 18 in. wide by 3 ft. long. This monitor is not automatic, the doors having to be opened and closed by means of the crank, as shown in the photograph. It is not advisable to use an attachment of this kind on planes where considerable capacity is lowered each day, unless a man is especially placed on top of the lower tipple to open and close the door.

If an automatic drop-bottom monitor is desired, they are constructed on the same plan as illustration Fig. 3, except the doors on the bottom of the hopper are extended about 10 in. beyond the roller bar of the hinge. On this extension is riveted enough weights to close the door after the coal is dumped. On the bottom of the hopper, just below the point where the doors meet, is the locking bar which is held in place by heavy guides. As the loaded car comes onto the lower tipple about 1 ft. above the dumping point, the locking bar, which extends about 12 in. over the car on both sides, strikes a trip rail which moves the locking bar beyond the edge of the upper door, allowing the coal to dump. At the same time, it raises a set of horns above the car, which strikes the locking bar and closes the hopper as the car goes up the plane. As these horns go down, they again raise the trips at the bottom which causes the bottom of the car to drop when it again comes down the plane.

Among the advantages of the monitor-car system are the following:

No mine cars are lowered down the plane, and consequently no coal spilling. They eliminate the labor of coupling a trip of cars. They require no special track as in case of "barney cars." If mine cars are run down the plane without a barney, there is a chance of a runaway with every coupling used. With the monitor car, there is one chance only of a break—the rope. However, the chief advantage of the monitor system is the saving of labor.

Track Arrangement

The arrangement of the track in any system of incline haulage is always a matter of considerable study and thought when installing a gravity system. The system shown in the photographs is adaptable to most any plane, and it will be noticed on the illustrations, Figs. 5 and 6, that below the passing point both cars go down a single track.

Referring to illustration, Fig. 5, it will be seen that the empty car will ascend the plane on the left-hand track, the loaded car coming down on the right-hand track having thrown the switch so as to return on the track it came down. This switch is provided with a weight which holds the points in the position desired.

Illustration, Fig. 1, shows the track arrangement at the top. The three-rail system, as shown on illustration, Fig. 5, becomes a four-rail system at a distance of 35 to 40 ft. from the loading chute. The two systems of tracking gradually come together until at the loading point the corresponding rails of both systems are but 4 to 6 in. apart.

Continuous Coking in Vertical Retorts

Special Correspondence

Describes a comparatively new departure in retort-oven practice, which is being successfully used in a number of plants. The continual exclusion of the atmosphere, eliminating the losses of heat, irregularities of carbonization, and insuring a maximum efficiency and recovery of byproducts is a unique feature.

The importance of coking processes in connection with colliery operations has received such acknowledgment within recent years that it is unnecessary to demonstrate the point here. The methods of coking, either at the colliery itself, or at the gas works which, although primarily occupied in the production of gas, also rely to a very large extent on the sale of the coke so obtained, have been so much improved within recent years, that some reference may be made to a type of vertical retort. Although only comparatively recently introduced, one oven of this variety has produced very excellent results. This is the Woodall-Duckham system of continuous carbonization, installed by Messrs. Duckham & Cloudsley, Ltd., of Westminster, London, in Great Britain, the United States, Switzerland and New South Wales.

Description of Retorts

The principle of this system is the regulated continuous descent of coal through a vertical retort suitably heated and constructed. The descent is regulated in speed by the coal which enters the top of the retort and is gradually carbonized in its downward passage until by the time it arrives at the bottom of the retort, it has been converted into coke. Both the amount of coal fed to the top of the retort, and the rate at which it passes downward, are regulated automatically by the rate at which the coke is extracted at the lower end of the retort.

The formation of this retort can be best understood by reference to Fig. 1 which shows the cross-sectional elevation of a single unit. The installation consists of four such units in each setting, together with the generator, regenerator and waste-gas flue common to each setting. The retorts are 25 ft. long, and have brick walls so tongued and grooved that leakage at the joints is impossible. Panels are formed in the back of the walls so that a large surface is presented to the heating flues which are vertical and the heat is readily transmitted through the walls to the charge in the retort. The gas from the producer and the secondary air are admitted at the top of the vertical flue in such a way that regulation of the amount of heat transmitted to the various portions of the retorts can be effected.

The generator, which is of ample size, is so constructed that the depth of coal from the fire bars to the point at which the gas is drawn off, is constant at all times; the regenerator is of the sandwich type, the walls between the waste-gas and secondary-air flue being formed of grooved on tongued paneled bricks similar to those used in the retort walls. The area of the regenerator is about 10 per cent. greater than that used with most horizontal settings of the same

capacity. In order to regulate the pull on each set, flue retort dampers are provided at the bottom of the retort, and in addition main dampers are fixed on the waste-gas outlet of the regenerator.

Method of Discharging

The regulator for determining the rate of discharge of the coke is fixed to the extractor, and has proved to be a very successful and efficient type. In such extractors it is necessary that they shall be quite free from the weight of the charge in the retort; that they should not cut or shear through the coke; that they shall have the same action on the coke at each point of their movement, thereby securing an even discharge; that they do not impede free access to the bottom of the retort, and that their method of drive is such that the speed variation is easily effected.

In order to fulfil these conditions the Woodall-Duckham extractor is situated along the bottom of a curved plate, forming the back of a cast-iron hopper fixed to the bottom of the retort. This curved plate, which takes the weight of the charge in the retort, is provided with manhole and inspection holes in order to give direct access to the retort. The extractor roller allows a definite amount of coke to pass over it into the lower receiving hopper without shearing the coke in any way, and hanging bars suspended from a shaft above the extractor prevent any coke from passing over unless regulated by the action of the extractor.

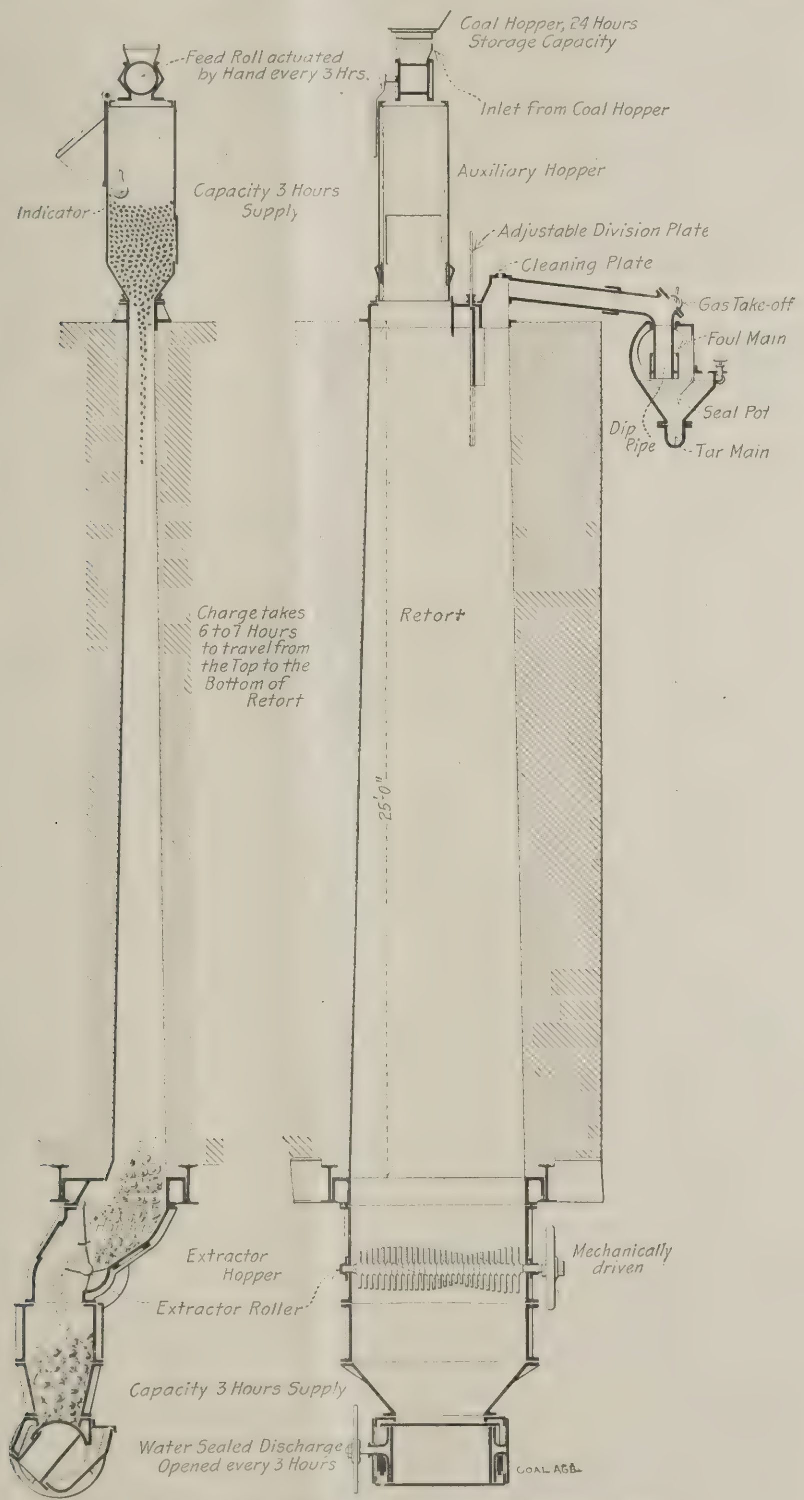

Fig. 1. Elevation in Section, Vertical Retort Oven

The actual extracting device consists of a series of short cast-iron cross pieces fixed on to a square shaft, so that each piece has a slight lead on its neighbor. In this way a roller of helical blades, is formed, producing a uniform regulating effect on the coke discharge throughout the whole of the revolution of the extractor and giving a constant travel of the charge down the retort. At the extension of the roller shaft is fitted a wheel with a V-shaped groove in which an eccentric wedge-shaped pawl is operated by a rocking arm. The travel of this pawl can be adjusted by the rocking arm, and these arms are in turn operated by means of connecting rods from a reciprocating bar running along a bench of settings; a variation of speed 20 per cent. faster or slower than the normal speed of rotation of the extractor (which is one revolution per hour or ninety minutes) can be obtained. The wear on the extractor owing to this slow speed is very small and the amount of horsepower consumed by it is quite low.

It will be seen by reference to the illustration that below the extracter roller there is a cast-iron receiving hopper which is designed to accommodate three hours' discharge of coke. The bottom of this hopper is closed by a water-sealed gas-tight door which presents a considerable improvement over some of the usual types employing tightening and clamping arrangements. It consists of two cast-iron boxes, one inside the other, the intervening space between being filled with water. In this space there is a segmental door plate mounted on a spindle and so counterbalanced that it can be operated for three hours by means of a wheel and spindle. When closed the door is immersed in four inches of water and is therefore gas tight and needs no clamping. Although the coke is not in contact with the water the castings are kept cool and any coke dust percolating into the water space can be easily cleaned out. The coke is quenched by means of a small spray of water in the storage hopper, and leaves the retort practically dry and at a temperature of about 130 deg. Fahrenheit.

Charging and Recovery of Byproducts

The top of the retort is closed by a cast-iron mouthpiece, to which is fixed the coal-feeding device, and the gas-out-

let pipe. The coal feed is effected by means of an auxiliary hopper fixed to the mouthpiece casing, and closed at its upper end by a circular valve. This hopper, which contains three hours' supply of coal, is filled in its turn from a main storage hopper above it. The circular valve, which is operated either by hand or mechanically, consists of a turned closed cylinder with two holes at its periphery on its diameter, giving a passage for the coal when these openings are opposite similar holes in a bored cast-iron casing in which the valve is rotated on a spindle. Each feeding hopper shows the rate of coal feed to the retort and the position of the coal in the hopper, by means of an indicator consisting of a weight resting on the top of the coal, which has a small wire attached to it passing through a gas-tight gland in the top of the hopper. The other end of this wire carries a pointer to the outside of the hopper and indicates upon a scale attached to it.

A gas off-take, 7 in. in diameter, is connected to an extension of the top mouthpiece and pipe, falling from the retort toward the foul main, forming a connection with this by means of a dip pipe and seal pot. The bottom of this pot is connected to the tar pipe, and in ordinary working the tar or liquid produced by the retort flows from the off-take pipe and foul main, direct to the tar pipe. When, however, it is desired to shut off the retort from the foul main the valve in the connecting tar pipe is closed and a 4-in. seal is formed in the seal pot, which effectually shuts off the retort.

Between the coal-inlet and the gas-outlet pipe there is fitted a division plate extending into the retort. This division plate is fitted with a sliding extension piece which can be lowered in the retort for the purpose of regulating the amount of free space in the retort through which the gas is to pass. It will be seen that this plate provides a free passage for the gas immediately above the zone of carbonization. and by the adjustable nature of the division the temperature of the gas leaving the retort is governed so that the maximum make can be obtained from coals of varying qualities by the fixation of hydrocarbon vapors which would otherwise be deposited with the tar.

A clear floor space in and around the retort setting is obtained by placing the whole construction on a rolled-steel floor joist carried by stantions. The buck staves are carried from the floor joists to the top of the setting and tied across these by steel joists. The main storage hopper for coal and coke, which holds 24 hours' storage of coal and 40 hours' storage of coke, is supported from the cross joists connecting the buck staves.

Summary of Advantages

This system has a considerable number of advantages as compared with some of the older forms, and these may be briefly summarized. Owing to the carbonizing process being automatic, easily regulated, and continuous, the characteristics of different qualities of coal can be met by variation of the conditions of carbonizing to insure a maximum production of gas and residuals. None of the coal is exposed to longer heating or greater temperature than other portions, and the coke made is of the same quality throughout. In some types of ovens and retorts it occasionally happens that the ejected matter contains a portion of coal which is only partially coked, but in this vertical continuous system such an occurrence is not possible.

Labor costs are reduced very considerably and local conditions are met by a simple regulation of the speed and temperature at which the process is conducted. An important point is that the coal descends gradually into an enlarging sectional area of the retort and free spaces are produced in the contents of the retort for the easy passage of the gas, and the greater proportion of such gas is given off long before the coal reaches the bottom of the retort, by which time the coal has been converted into coke. In this way the difference of gas pressure between the top and bottom of the retort is not more than one-tenth of an inch, and the free passage of gas considerably reduces the amount of carbon deposited on the walls of the retort as scurf. Moreover, the scraping action of the solid contents in descent minimizes such deposit. In practice it is found that the scurf only needs to be removed once in ten or twelve weeks, and this is the only time when the retort has to be opened to the atmosphere.

This system of carbonization, by securing that the retorts are always closed to the atmosphere and that the coke when discharged is already quenched, avoids the loss of heat or gas which is found in some of the intermittent coking systems, and hence the fuel consumed in the generators is very much reduced. This efficiency in working is further increased by the fact that by the flexibility of the feed which is given, the contents of the retort only remain there for sufficient time to complete the coking. In contrast to some other systems there is no emission of smoke, dust or steam during the working of the retorts, which leads to better conditions of working, and the reduction of attention required, to practically that of supervision. In congested areas the elimination of nuisance or damage to surrounding buildings is a most important advantage.

The even and regular temperature at which the retort setting is worked and the comparatively low value of this temperature as compared with that of some other systems, exercises a very beneficial effect on the maintenance. In addition to this there is the fact that the vertical retort system described above, economizes ground space in relation to the quantity of fuel carbonized in a given time, while it is very easy to arrange coal- and coke-conveying apparatus on a simple system of feed in large installations of such settings. As the whole of the working parts of the installation are above ground level, the advantages of easy access, good ventilation, and adequate lighting are secured, and for these reasons the Woodall-Duckham system is finding very considerable favor in the undertakings where it has been tried.

Safety Lamps

The "Mines and Quarries General Report with Statistics for 1910" (England) contains interesting data relative to safety-lamp practice in Great Britain.

The total number of miners' electric hand lamps in use during the year 1910, was 2055, or 0.28 per cent. of the total, as compared with 2155, or 0.32 per cent. of the total in use during the preceding year. A great majority of the lamps are used in Durham—namely, 1797—and their use is practically restricted to one colliery.

The number of the various kinds of safety lamps in use comprises 219,990 Marsaut, 107,958 Ackroyd & Best, 82,968 Protector, 72,707 Clanny, 66,483 Cambrian, 26,196 Muesler, 24,830 Deflector, 19,943 Patterson, 13,301 Byfold, 11,774 Wolf, 11,047 Thorneberry, 10,453 Baxendale, 7785 Donald, 7465 Davis, 5165 Park Lane, 4355 Davy, 3825 Routledge & Johnson, 2055 electric, 7182 other kinds and not stated.

The total number of safety lamps in use in Great Britain is 705,482, of which 381,596 have single gauzes, 321,408 two gauzes and 407, three gauzes. The number of shielded lamps is 670,307 as against 32,705 unshielded. Head-rivet locks are used on 408,593; magnetic on 208,267; screw on 72,352; others, 16,270. Colza oil as an illuminant is used for 508,805 lamps; petroleum for 67,134; volatile spirit for 88,153; electricity for 2055; other illuminants, 39,335. Number of lamps initially lighted by electricity is 310,457; by internal igniters, 11,197; by opening, 383,828.

A barometer and thermometer should be placed above ground in a conspicuous place near the entrance of the mine. Readings should be taken at the commencement of each shift and records kept of the same. A falling barometer shows a decrease in atmospheric pressure; a rising barometer shows an increase in pressure. A lessened pressure favors the formation of gas and falls of roof

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of COAL AGE, we will print 6250 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

COAL AGE

Danger Periods in Mines

That it is possible to discover and, to a limited extent, to forecast the approach of what may properly be termed a "danger period" in mines, is growing more certain each year.

Attention has been called frequently to the fact that mine explosions often occur in groups. There will be times when for weeks and even months the public are horrified by the continued reports, in the press, of mine explosions occurring in rapid succession. At times, a longer or shorter period will follow when there is a cessation of these disasters. This period of immunity may be, and often is marred or broken by the occurrence of one or more erratic mine explosions—the result of someone's foolhardiness, neglect or carelessness. But such erratic happenings in no way disprove what is fast becoming an established and evident law, that there is some great underlying influence that operates quietly but powerfully to disturb the security of coal mines, and endanger the lives of workers therein.

So little is known of the hidden causes whose periodic effects are so manifest and terrible, that it would be presumption to attempt to predict how long any such periods of immunity or of danger might last. A danger period may gradually grow and increase in intensity during weeks; or the period may be ushered in by a violence that commands the profound recognition of all. Again, the termination of danger may be abrupt or gradual. There is no defining the law of longevity, in this regard, for the evident reason that no such law exists or can exist.

The periods, long or short, are the result of conditions buried in the mysterious depths of Mother Earth, or enveloping her in the unfathomable sea of air above. These conditions, it is needless to say, are beyond the extent of human ken; and, at the most, their effects are but feebly measured.

The fact remains, however, that, notwithstanding our ignorance of the causes, there is an undeniable periodicity in the ocurrence of mine explosions; and it is well to draw the attention of investigators to this fact. For a number of years it has been the opinion of many that there is a more or less synchronous or corresponding periodicity in seismic disturbances.

There is a recognized difficulty in the attempt to correlate such phenomena, because of the plain fact that a period of danger in mines may or may not be emphasized by the occurrence of mine explosions. On the other hand, the accumulation and ignition of gas may take place in a mine, at any time, owing to carelessness, neglect or the relaxation of vigilance. Because there is danger, it does not follow that accident will occur; and when accident does happen, it is not always a consequence of existing danger.

Many times the periods of severe seismic troubles have been accompanied by like disastrous periods in mines. The ever-memorable Mt. Pelée eruption, in the Island of Martinique, West Indies, May 20, 1902, costing 30,000 lives, was accompanied by the loss of nearly 600 lives in four mine explosions: Fraytervillе, Tenn., May 19, 184 lives; Coal Creek, Fernie, B. C., Can., May 23, 127 lives; Johnstown, Penn., July 10, 112 lives; Mt. Kembla, New South Wales, Aug. 1, 127 lives, and numerous other accidents, in which the loss of life was not so great.

Again, the great earthquake in the north of India, in 1905, killing 35,000 people, was signalized by no less than 13 mine explosions of record, in this country alone, which cost over 300 lives.

The terrible earthquake that destroyed thousands of lives, and property to the value of $45,000,000, in the Island of Formosa, Japan, Mar. 17, 1906, was marked by the Courrières mine explosion, France, Mar. 10, 1200 lives; Century mine, W. Va., Mar. 22, 21 lives; and Takashima mine, Kiushu, Japan, Mar. 28, 307 lives. A few days later, Apr. 3, Mt. Vesuvius again let go, destroying hundreds of lives and many towns and villages; while a repeated earthquake again destroyed the

town of Kagi and killed 109 persons in Formosa, Japan, Apr. 7, to be supplemented by the terrible San Francisco earthquake Apr. 18; and the mine explosion, near Trinidad, Colo., Apr. 20, costing 22 lives.

The present time is undoubtedly a period of danger. The trouble has been seemingly accumulating during the past 10 or 12 months, as told by the recorded earthquakes in Costa Rica, Mexico, Hungary, and the eruptions of Aetna, in Sicily; interspersed by serious explosions in the mines at Trinidad, Colo.; Tonopah, Nev.; Throop, Penn.; Littleton, Ala.; Elk Garden, W. Va.; DuBois and Punxsutawney, Penn., and now at Briceville, Tennessee.

It would be well for all mine foremen and firebosses, as well as all mine employees working underground, to exercise more than ordinary caution in respect to the gaseous condition in the mines in their charge. By so doing it may be possible to avoid an accident that, though unexpected, may be imminent. The old proverbs "Forewarned, forearmed," and "An ounce of prevention is worth a pound of cure," are particularly applicable here and now.

Much interest in the work of investigating the question of the possible relationship of seismic disturbances and the appearance of gas in mines, has recently been developed by an address given before the Board of Trade, Victoria, B. C., Can., by F. N. Denison, who has been conducting some special research work in that region. The address pointed out the particular fitness of Victoria, as being a suitable site for the establishment of an observatory, by the Dominion government, for conducting investigations of this character. It was argued that Victoria was in close proximity to one of the great seismic belts of the earth extending along the Pacific Coast from Alaska; another belt being the Japan belt, running through the Island of Formosa, Japan.

Compulsory Use of Safety Lamps

A solution of the question as to when the use of safety lamps should be made compulsory has been offered by our English brethren. It is extremely elementary in character, and provides in brief that protected lights shall be used in seams where a personal injury from an explosion of gas has occurred within 12 months.

As is pointed out, the merest "singeing of a man's whiskers" may, according to this rule, compel the adoption of safety lamps in a comparatively safe mine. On the other hand, the law embodies some of the features of locking the barn after the horse is stolen. A dangerous mine may be operated for some time on a semi-openlight basis with no minor casualties, and yet eventually be the scene of a fearful disaster.

It does appear that our English colleagues might solve their problems along more scientific lines.

The Sauve Qui Peut

How men hemmed in after an explosion should save themselves demands careful consideration and it does not seem that it has received the thought it deserves. It is true that W. E. Garforth has suggested some excellent rules for recovering mines after explosions and fires, but these rules do not apply to the workingman who is trapped behind an explosion or about to be overwhelmed by its advancing waste products. Not only should the best talent of the profession consider a code of rules, but these rules should be posted at all mines and be signed by the mine inspectors so that when the fierce *sauve qui peut* comes, the men may have some guide to follow, some definite idea of what is needed. The call for such judgment will become more marked as the dampening and ventilating of the mines become better developed, for then there will be little dry dust and little accumulated gas to make explosions mechanically destructive. Then the products of combustion will suffocate or poison more persons than they destroy by their violent expansion or the direct heat of their combustion.

No one cares to be first in posting such rules. The mine at which such posting took place would bear, as it were, the "scarlet letter" placed there by the managers of the operation. To some workingmen it would appear an ominous admonition to remove their tools; to others an acknowledgment on the part of the company that the mine was unsafe and the officials knew it and did not intend to take the requisite steps to safeguard its men.

Hence the rules of safety should be posted at all mines; the mine where the possibility of an explosion or a fire seems remote, and to some shallow thinkers almost impossible, as well as at the mine where the sad probability of its happening casts a heavy veil of gloom over the inhabitants of the mining village. And such a general posting of rules will doubtless result in a more general consideration of what those rules should cover and how they should read.

The simple rule "escape to the intake" will perhaps apply when the explosion lies further along the path of the air current than the entrapped man. But if the explosion is on the other side of him, his chances would be better if he took the return and strove by activity to outdistance the advancing column of stupefying gases or to get into another split of the intake or a diluted return. Or again, a better plan might be in that case for the miner to wall himself in the end of a heading or other *cul-de-sac*.

On consideration, does not the rule take the almost ridiculous form, "Run away from the explosion if you know or can ascertain where it occurred." It seems so simple, such a primal instinct, that to print it is to suggest a lack of humor; but as a matter of fact, at Vivian, the men who were safe where they were, and who, it would seem, must or could have had some inkling of the direction in which the explosion had taken place, plunged thoughtlessly into the gas and died; at Adrian and Sykesville it was the same story, the men breathed the foul current and fell dead.

But the point of origin of an explosion is so obscure, that even though the force be slight and the intervening time short, a safe deduction is rarely to be made. So perhaps a better rule would be, "Strive to escape speedily along airways where the air is good. When you come to foul air, go cautiously. If it gets worse you are probably approaching the explosion and should stop and seek another road. In any case walling oneself in a 'dead end' is to be preferred to a desperate flight through foul air."

What is needed is a cool head in time of an explosion. Nothing provides that cool head like continued aforethought. In this is found the chief value of drills; fire drills at schools, boat-lowering drills at sea and the formation drills in the army.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Interesting Questions Made Simple for Beginners

Diffusion of Gases

Ques.—(a) What is meant by the *diffusion of gases?* (b) State the law of the diffusion of gases, commonly known as "Graham's law." (c) Show the application of the law of the diffusion of gases, by finding the relative volumes of marsh gas (CH_4) and carbon dioxide (CO_2) in the mixture of these gases formed under such conditions that the undiluted gases diffuse into each other without becoming, first, mixed with air.

[*Note*—The condition (c), mentioned here, may and often has occurred when working a seam generating marsh gas and underlying an abandoned seam, a few feet above, in which much blackdamp has accumulated].

Ans.—(a) By the *diffusion of gases* is meant the intermixing of the molecules of the gases according to a fixed law, which gives, always, a mixture of exact proportions. Diffusion is different from simple mixing, because gases may mix in any proportions, but they diffuse only in proportions which are fixed and known.

In the mine, diffusion and mixing take place together, in most instances. It is only when two gases, or a gas and air, are separated by a porous stratum, or when an occluded gas issues from the pores of the strata into a confined space where the air is dead (not moving)—it is only under these conditions that diffusion alone takes place.

The Law of Diffusion of Gases—Graham's Law

(b) Graham found, by experiment, that when two gases of different densities are separated by a porous diaphragm, which prevents the gases mixing, diffusion takes place through the pores of the diaphragm, a certain portion of each gas passing into the space occupied by the other.

Law—The velocity with which gases diffuse into each other, or into air, varies inversely as the square root of the density of the gas referred to air as unity.

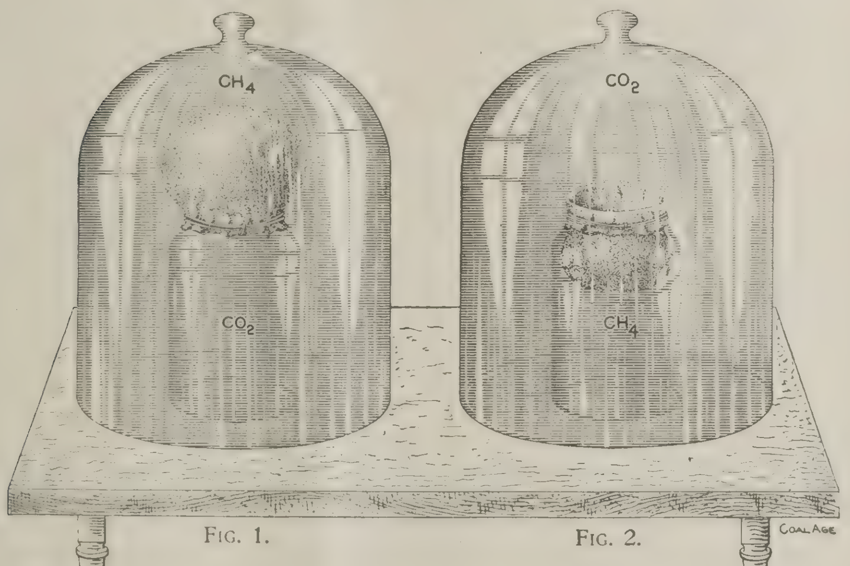

Fig. 1. Fig. 2.

Two Experiments, Showing the Diffusion of Marsh Gas Is More Rapid than that of Carbon Dioxide

The relative velocities of diffusion, for the important mine gases, calling that of air 1, are as follows:

TABLE GIVING SPECIFIC GRAVITY AND RELATIVE VELOCITY OF DIFFUSION OF MINE GASES
(*Air* = 1)

Gas	Specific Gravity	Relative Velocity of Diffusion
Marsh gas	0.5590	1.3375
Carbon monoxide	0.9670	1.0169
Nitrogen	0.9713	1.0147
Olefiant gas	0.9780	1.0112
Air	1.0000	1.0000
Oxygen	1.1056	0.9510
Hydrogen sulphide	1.1912	0.9163
Carbon dioxide	1.5290	0.8087

An Interesting Experiment

A very interesting and instructive experiment that can be performed to advantage, in mining-institute classes, is the following:

Fill a glass fruit jar, Fig. 1, with carbon dioxide (CO_2), and tie a bladder securely over the mouth of the jar. Place over this a large bell-jar that has been previously filled with marsh gas (CH_4), or hydrogen (H). Immediately diffusion of the gases begins, the gases passing through the bladder. But, as shown in the table above, the rate of diffusion for marsh gas is much more rapid than that for carbon dioxide; and, consequently, more marsh gas passes into the fruit jar than carbon dioxide passes out. As a result the bladder is expanded gradually, as shown in the figure, till it bursts under the pressure of the gas. If the fruit jar is filled with marsh gas and the bell-jar with carbon dioxide, the reverse of this takes place. More gas, then, passes out than into the fruit jar, and the bladder is depressed, as shown in Fig. 2.

(c) To properly answer this part of the question will require more space than is available this week. It will be answered fully in the next issue.

Blackdamp in Mines

Ques.—What relation has blackdamp to air in respect to specific gravity?

Ans.—Blackdamp, as commonly understood in mining language, consists chiefly of carbon dioxide (CO_2), which gas is about one and a half times as heavy as air at the same temperature and pressure. Hence, the specific gravity of blackdamp, referred to air as unity, is 1.529, which is the specific gravity of carbon dioxide.

Ques.—Where in a mine is blackdamp usually found?

Ans.—The presence of blackdamp, in mine workings, depends on the conditions that exist in the different parts of the mine. It often occurs where its presence was not suspected, working through the crevices of a broken roof, from the abandoned workings of an overlying seam. It occurs, commonly, in poorly ventilated places where combustion, in some form, is taking place, and the air-current is not sufficient to keep the place clear of the accumulating gases. Blackdamp accumulates in the lower portions of the mine, at the floor of chambers, and in dip workings, because of its great density, being half again as heavy as air.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

An Ingenious Arrangement

The company with which I am connected recently took over a mining property which had been worked for a number of years. A haulage road of this mine and three slopes, lying 600 to 800 ft. apart, are indicated in Fig. 2. Cars were drawn up each of the slopes by a small hoisting engine and delivered at the head of the plane to a steam locomotive, which traveled along the haulway.

The hoisting engines were run by compressed air, supplied from a compressor located about ¾ of a mile from the nearest engine. This arrangement required the services of three engineers, in addition to the locomotive crew and an attendant for the air compressor. The compressed-air installation was plainly inefficient; the locomotive and several hoisting engines lay idle a large part of the time, and, on the whole, an expense was involved out of all reasonable proportion to the output.

As I have stated, this is an old mine, and while still productive, was not considered sufficiently remunerative to justify any considerable investment for improvements. Our problem was, therefore, to find some means for reducing the excessive cost of coal from these slopes without making more than a nominal outlay of money.

The solution which was finally adopted consisted in doing away entirely with the air compressor and in supplying high-pressure steam to the hoisting engines from the steam locomotive by means of a swinging pipe connection, as pictured in Fig. 1. In operation, the locomotive is now run to each slope in turn and coupled up with the hoist. The cars are then hauled up the plane and the locomotive, after being uncoupled, takes them away.

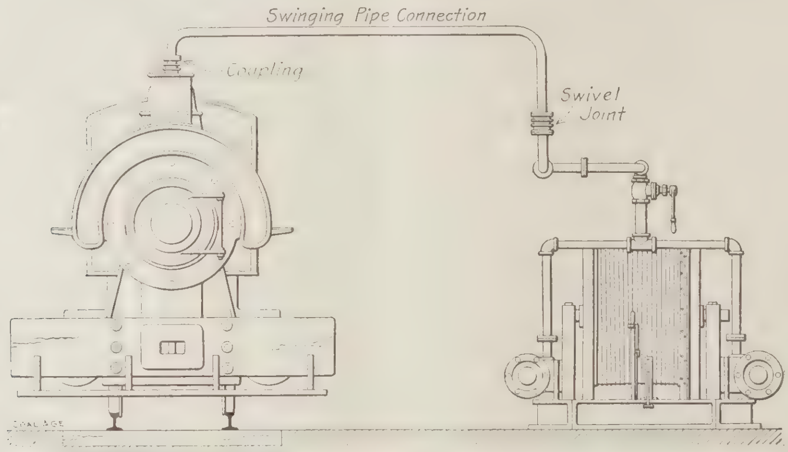

Fig. 1. Detachable Steam-pipe Connection

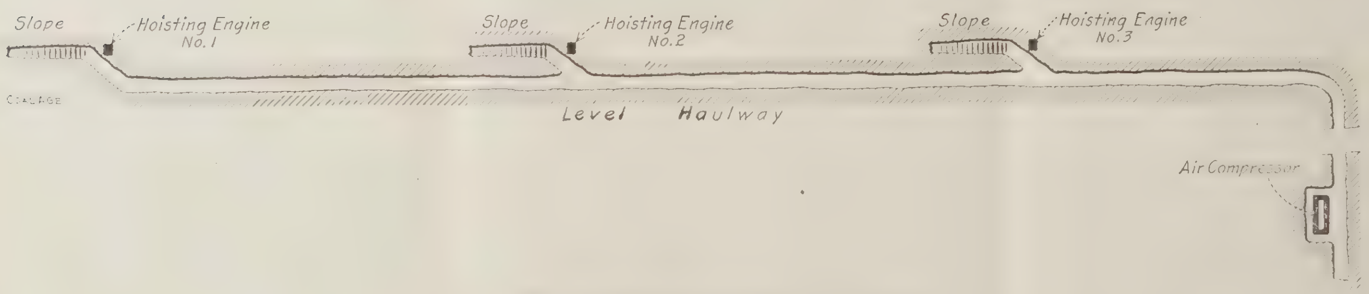

Fig. 2. Plan Showing Slopes and Haulway

The use of high-pressure steam in the hoisting engines enables them to do their work in a fraction of the time previously required, and thus makes it possible for the locomotive engineer to pass from one to the other without in any way reducing the amount of coal hoisted.

It is estimated that as much as $15 to $16 per day was saved by this method of operation. The device is, of course, nothing more than a clever makeshift applied to unusual conditions, but as such, has points of interest and possibly might be applied elsewhere with good results.

Pottsville, Penn. E. J. E.

A Cause of Explosions

I have just read the editorial relating to "Humidification" in the issue of Dec. 2. Everybody will admit that water is a good fire extinguisher and I have no objection whatever to its use in dry mines, but I shall continue to give well founded warning that the application of moisture cannot be depended on to stop an explosion when once under way; and I go further than that, it should not even be relied on to prevent the occurrence of a dust explosion. I agree with Taffanel that watering for a considerable distance in front of shots about to be fired lessens considerably the danger incident to blown-out shots, but it does not eliminate that danger entirely. It should be remembered that a mine is not a testing gallery, where conditions can be regulated to a nicety. At the Banner mine in Alabama nearly 100 sprays, spaced 100 ft. apart, constantly injected vaporized water into the mine air, but this complete and well arranged installation failed to prevent an explosion, which, notwithstanding these precautions, occurred at that mine.

I heartily agree with the editorial that "each operator should prove conclusively that humidification is either not needed, or harmful, etc." That is a fair proposition and will bring results which cannot be secured through forcing the sprinkling of mines by enactment of law.

I have stated repeatedly that the use of steam as an alleged preventive of dust is preferable to any system of

sprays or vaporizers, not because steam is a good humidifier, but because it raises the temperature of the ingoing air and therefore weakens the force of the strong natural draft along the mine floor during the colder months of the year when the explosion danger is most pronounced.

To show the difference in air-flow in mines at different seasons of the year, I submit some measurements that were taken in the same mine and at the same place, about ¼ mile from the downcast, the height of entry between collar and rail being 5 feet.

VELOCITIES OF DIFFERENT LAYERS OF AIR

August 5, 1908: Outside temperature, 88 deg. F. Inside temperature, 58 deg. F.

Distance Below Collar in Feet	Velocity of Air, Feet per Minute
1	178
2	178
3	140
4	120
5	73

March 19, 1908: Outside temperature, 20 deg. F. Inside temperature, 48 deg. F.

Distance Below Collar in Feet	Velocity of Air, Feet per Minute
0 (underside of collar)	140
2½	280
5 (top of rail)	235

Jan. 30, 1909: Outside temperature, —9 deg. F. Inside temperature, 40 deg. F.

Distance Below Collar in Feet	Velocity of Air, Feet per Minute
0 (underside of collar)	200
½	230
1	300
2½	400
4	400
4½	490
5 (bottom)	300

April 20, 1909: Temperature at bottom of downcast, 47 deg. F. Inside temperature, 49 deg. F.

Distance Below Collar in Feet	Velocity of Air, Feet per Minute
½	160
1	200
2	230
2½ (center)	250
3	230
4	210
4½	180

By comparing measurements of Aug. 5, 1908, and Jan. 30, 1909, and accepting Mr. Hall's view relating to the "advance," it will be readily seen how the manner of air-flow may be an influential factor in determining the "rate of advance." Time and further investigation will show that Mr. Hall is on the right track and that beyond a doubt "the rate of advance," or in other words, the intensity of draft rather than the amount of dust present determines the magnitude of a dust explosion.

Mr. Hall believes that the Adrian explosion was caused by a short-circuit. From the evidence available, it seems that his conclusion is probably correct. It has been shown, however, that a wire at white heat inserted into a dust cloud did not ignite the dust. It was further proved by Holtzwart and Meyer that lignite dust could not be ignited by a short-circuit when the dust was merely in suspension around it, but when the dust was puffed between the terminals by compressed air, ignition occurred. In view of this the logical explanation of the Adrian explosion seems to be that the wires were knocked down to the floor by a fall, a short-circuit resulted, and the draft along the bottom carried the dust and air with sufficient force and in sufficient quantity to the electric arc to cause a small explosion. The latter stirred up more dust and increased the draft ("rate of advance") toward the arc with subsequent disastrous results.

The main factor in the Delagua explosion was a draft. There is no question about that. It was so in the Starkville explosion which resulted from a short-circuit and, in my judgment, it is so in every explosion. The raise and disturbance resulting from a blown-out shot are spectacular, but it is the size and duration of flame, the draft facilities and the fuel carried by the draft which determine the extent of the danger.

I may be mistaken in my views, but I think there is at least foundation enough for them to have them put to a fair test. I have given much consideration to the dust-explosion problem during the last 20 years and I have given the results of my investigations with the hope that they may be of some benefit to the mining interests of this country.

Chariton, Iowa. JOHN VERNER.

The Firebosses' Problem

I would like to echo the suggestions made by "Fireboss, Western Pennsylvania," in COAL AGE, Nov. 18, 1911, page 190. The same conditions that exist, in this regard, in Pennsylvania, exist here in West Virginia. The fireboss who would make a true report of the condition of the mine or district in his charge dare not do so, because of the fear he entertains of losing his job. On the other hand, should he be found by the state inspector, to have made a false report, he would be liable to a fine or imprisonment, or both.

I venture to say that if all firebosses were employed by the state and under the supervision of the state mine inspector, instead of being in the employ of the mine operator, there would be less risk run, in numerous cases, and fewer accidents would occur. Why should the fireboss be forced to work under these conditions? As has been explained, he must be a man with quick, keen eyesight and hearing, and above all must be able to keep cool and not lose his head or his nerve. The safety of everyone working in or about the mines depends on the fireboss doing his work right. One little mistake on his part may cost hundreds of lives, and send the men whose lives are in his charge, without a moment's warning, from time into eternity. The same may occur as a result of the fireboss being compelled to assume risks that he would not be willing to take had he not been afraid of losing his job.

Mr. Superintendent, do not press your fireboss to allow a place to work that he considers dangerous. Mr. Mine Boss, do not go into the mine and throw aside your firebosses' danger boards until you have made a careful and thorough inspection of each place. The few tons of coal that you hope to gain for the company by so doing, would fail to recompense those who might be suddenly bereft of loved ones—in most cases, their breadwinners and sole support.

I hope COAL AGE will publish these few lines and that other firebosses will push this suggestion along and not let it die. I also hope, that state inspectors and state legislators will seriously consider the question whether it would not be the right thing for the state to enact a law making the fireboss a sub-mine inspector who would work under the supervision and control of the district mine inspector, who proceeds against him, legally, if there is trouble growing out of any failure on the part of the helpless fireboss to perform all the law requires. On the other hand, should the fireboss lose his job, because he refuses to accede to the plainly expressed wishes of his superiors in office, to declare a doubtful section of the mine in his charge, as *safe*, the law offers him no protection. He suffers alone, for his steadfastness in carrying out the law, and for his conscientious regard for the safeguarding of the lives of his fellows and the property of his employers.

A WEST VIRGINIA FIREBOSS.

Mr. Conner's Reply to Jos. Virgin

I note the communication from Jos. Virgin, of Plymouth, W. Va., which you have headed "Fair Play for the Mule." This letter comments on my article in the Nov. 18 issue of COAL AGE and I fully agree with Mr. Virgin, that in making comparisons between mechanical and animal transportation, underground, it would be unfair to the "mule," unless equally efficient rolling stock, and track arrangements are installed, for animal transportation, as for mechanical. In the comparison quoted in my article, however, I would say that the track arrangements where mules were used, were equally as good as where the gathering locomotives were installed.

It has been my observation that the cost of gathering mine cars with mules, where grades do not exceed 8 per cent., against the empty cars, and where the average haul does not exceed 1500 ft., is reasonably economical.

It must be understood, that in recommending electric gathering locomotives, no hard and fast rule can be laid down, as all of the local conditions affecting the efficiency of the motive power, must be carefully considered before determining upon the kind of power to adopt.

Philadelphia, Penn. ELI T. CONNER.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

The Flame Test

What is meant by the flame test?

A LAYMAN.

Knoxville, Tenn.

It is the test made to ascertain the possible presence of gas in air by observing the flame of a safety lamp. The favorite lamp for making this test is the Davy lamp.

Capacity and Speed of Belt Conveyers

Kindly give me your advice on the following proposition:

A 30-in. conveyer belt, running at a speed of about 200 ft. per minute, is handling 150 tons of fine crushed coal per hour, which is about the maximum capacity of the belt for this speed. It is desired to increase the tonnage from 150 to 250 tons per hour. Can the capacity of this belt be increased by increasing its speed, and to what extent may this be done?

I wish you would not only give the proper answer, but show how it is determined for my guidance in the future. Also, please show how the maximum desirable speed of driving any size of belt conveyer is ascertained.

I may say that I am interested in a proposition where a 30-in., 9-ply, special reinforced-rubber belt, 600 ft. long, will have to be renewed shortly. This belt runs over a 36-in. tail pulley to a 52-in. head pulley, rising at an angle of about 22 deg. The troughing rollers on the carrying side are 6 in. in diameter, and spaced about 5 ft. apart. The guide rollers on the return side are about 10 feet apart. The material is delivered easily to the belt by a chute. I would appreciate any suggestions from COAL AGE that would make this proposition more economical.

INQUIRER.

This is an interesting and important question in coal-mining practice, as belt conveyers are finding a rapidly increasing application in the handling of coal at the mine, and in loading and unloading large shipments at 'ifferent points. Belt conveyers operated by a small dynamo have been used successfully for transporting the coal along the face of longwall workings, in thin seams, where the mine cars cannot be taken.

In making the following reply to this question we are indebted to the Robins Conveying Belt Company, who have kindly furnished full information in regard to the speed and capacity of belts of varying widths. The Robins chart, reproduced on the opposite page, shows, almost at a glance, practically everything desired in reference to the speed, capacity and size of belt required for handling material, both sized and unsized, the lumps varying from 1½ to 14 in. in diameter.

Referring to the chart, it will be noticed the vertical lines represent cubic feet of material handled per hour, as read from left to right, at the top. The horizontal lines, reading up, at the left of the chart, represent the weight of material handled in tons per hour.

Crossing the chart are two series of diagonal lines; the upper one representing material of different density, varying from 20 to 150 pounds per cubic foot. The lower series of diagonals represents the required width of belt for any given capacity and speed.

On the right of the chart, reading up, is a scale giving the speed of the belt, for different widths and capacities. A close inspection of this portion of the chart shows that, for the same capacity, the speed of the belt varies inversely as the square of the width; or, for the same speed, the capacity of a belt varies with the square of its width.

In simple language, to deliver the same quantity (cubic feet per hour), a conveyer belt one-half as wide as another must be run at four times the speed. Or, running at the same speed, a belt one-half as wide as another will deliver only one-quarter the quantity of material.

For engineers who desire a formula, this relation of capacity (c), speed (v), and width (w) of conveyer belts is expressed as follows:

$$\frac{c_1}{c_2}=\frac{v_1}{v_2}\left(\frac{w_1}{w_2}\right)^2.$$

In comparing two conveyer belts operating under like conditions and handling the same material, the tonnage ratio is always equal to the product of the speed ratio and the square of the width ratio.

For example, suppose a 16-in. belt, running at a speed of 150 ft. per minute, delivers 60 tons of a certain material per hour, and it is desired to find the tonnage of a 40-in. belt, running at a speed of 80 ft. per minute. Call the required capacity of the 40-in. belt x; then, applying the above formula,

$$\frac{x}{60}=\frac{80}{150}\left(\frac{40}{16}\right)^2=\frac{8}{15}\left(\frac{5}{2}\right)^2$$

$$x=\frac{60\times 8\times 25}{15\times 4}=200 \textit{ tons per hour.}$$

The following directions are given by the Robins Conveying Belt Company for reading the chart. To find the width and speed of belt required to handle a given tonnage per hour of a given size and weight of material in pounds per cubic foot proceed thus: Enter the chart at left and follow the horizontal line marked by the given tonnage to its intersection with the diagonal line corresponding to the weight of the material per cubic foot. From this point drop down on the vertical line to its intersection with the diagonal line in the lower series, corresponding to any desired width of belt. From this point, again follow the horizontal line, to the scale of speed marked on the right of the chart.

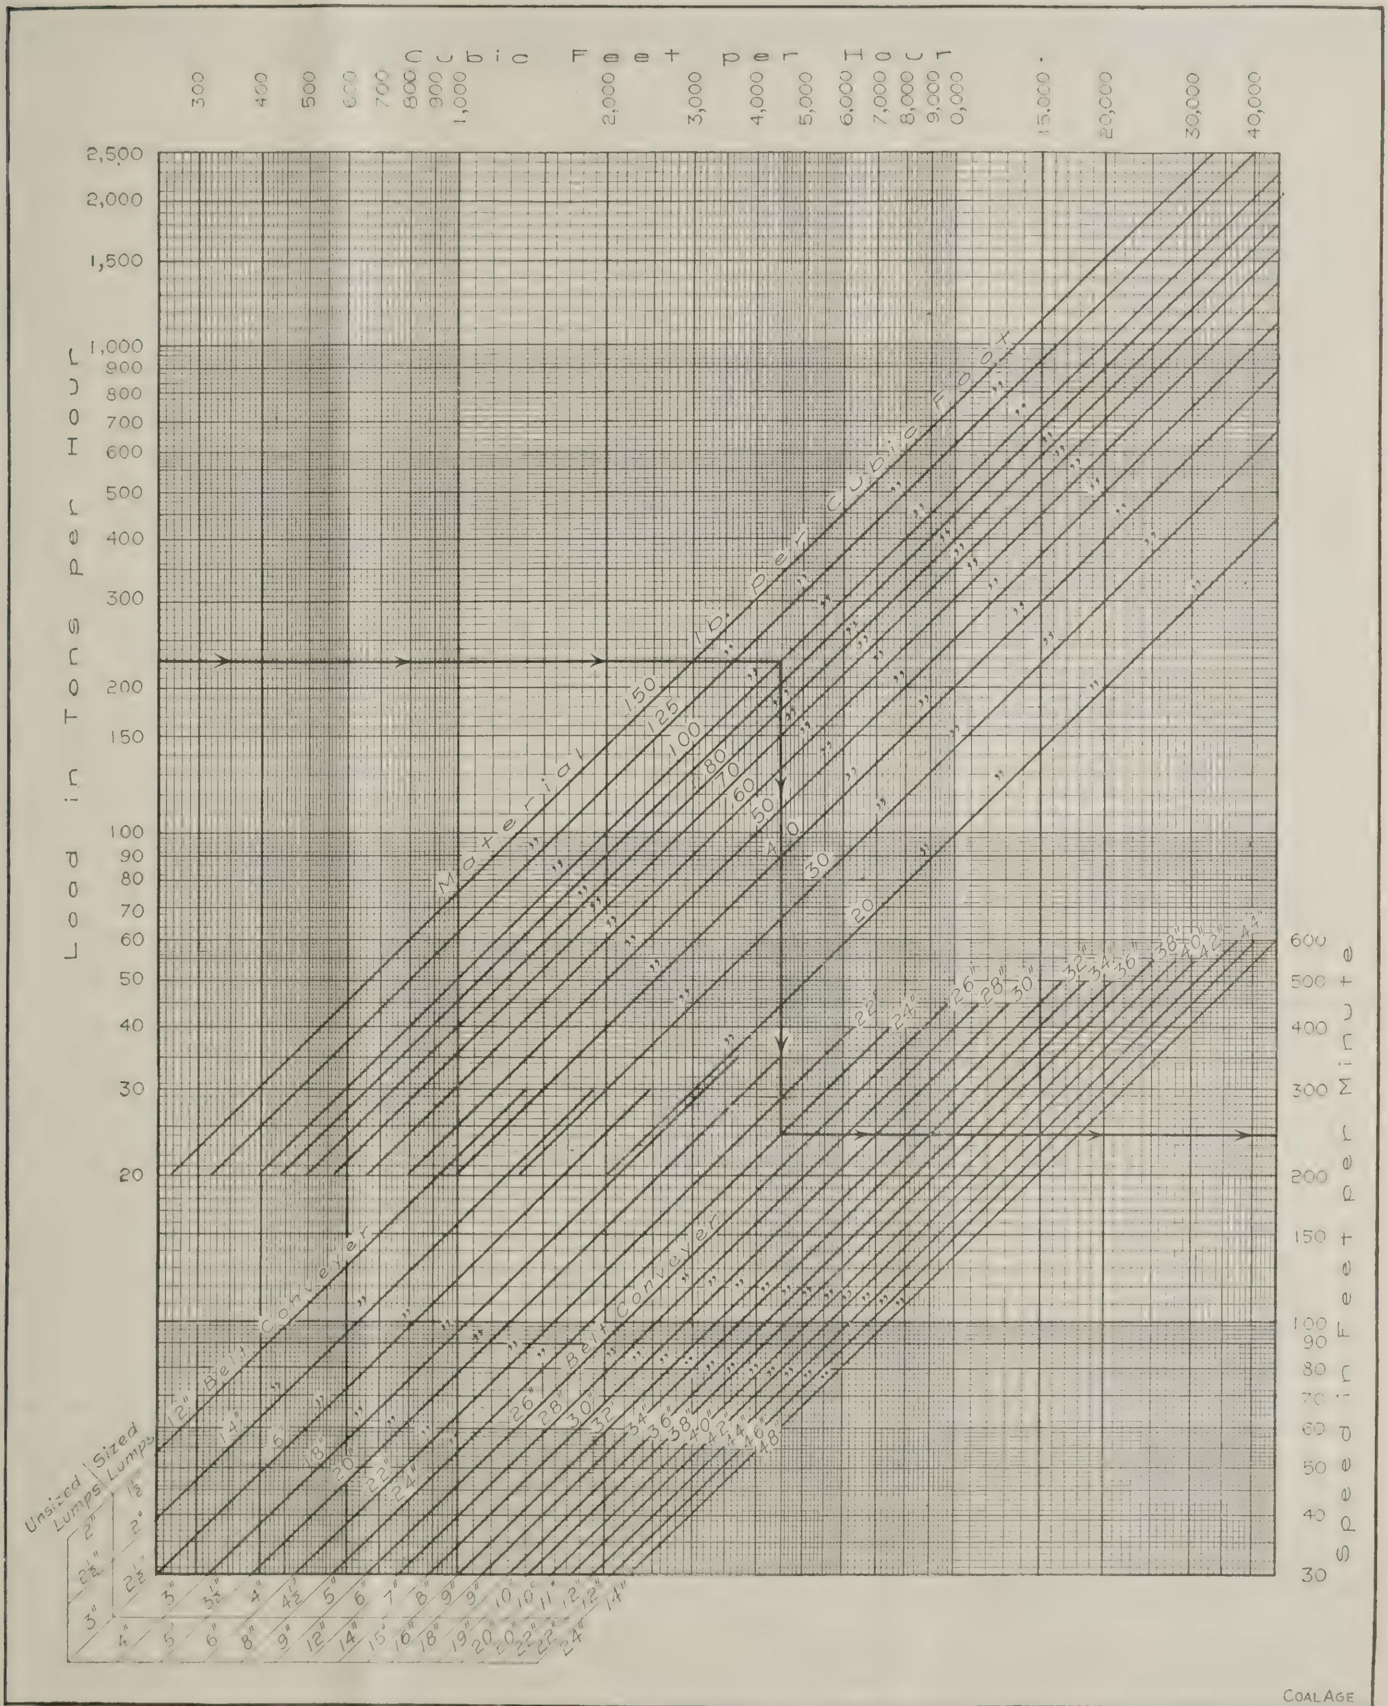
The heavy line crossing the chart shows that a 24-in. belt would have to be run at a speed of 240 ft. per minute, in order to handle a tonnage of 225 tons per hour of material weighing 100 lb. per cubic foot.

The two scales at the lower left-hand corner of the chart show what width of belt is preferable for handling different sizes of material, the inner scale being for lumps of a uniform size and the outer one for mixed material, the scale reading indicating the maximum size of lump. The heavy line just referred to is for a belt handling mixed material when the lumps do not exceed 8 in. With finer material when the lumps do not exceed, say 5 in., there would be required in the case cited above, a 20-in. belt running at a speed of 350 ft. per minute; or, for 14-in. lumps, a 30-in. belt, running at a speed of 155 ft. per minute.

Cubic feet per hour can be converted into tons per hour, for material of any given density (weight per cubic foot) by entering the chart at the top and following down the vertical line corresponding to the given cubical capacity, to its intersection with the diagonal corresponding to the given density or weight of material. From this point follow the horizontal line to the tonnage scale on the left. By reversing this process the cubic capacity corresponding to any given tonnage and material may be found.

In all cases the lower diagonals for different widths of belts are terminated

at the horizontal line marking the maximum desirable speed for the belt. In answer to our correspondent's question, "Can the speed of the 30-in. belt he has in use be increased so as to augment the tonnage from 150 to 250 tons per hour?" we reply, yes; the speed would have to be increased in the same ratio as the tonnage; or $\frac{250}{150} = \frac{5}{3}$, which would give a speed of $\frac{5}{3} \times 200 = 333$ ft. per min. The chart shows, however, that the maximum speed for a 30-in. belt is 450 ft. per minute.



Capacity and Speed Chart of Belt Conveyers

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

Governmental Inquiry into Liquor Consumption

The Immigration Commission has furnished some important information with reference to the liquor problem in mining communities as a result of careful investigations of the question which have been carried on with a view to tracing the effects of the use of alcoholic liquors and their relation to efficiency in the production of coal. The results of the inquiries show that there was a direct relationship between the consumption of liquor and the efficiency of the employees.

The consumption of alcoholic liquors among the immigrant employees is exceedingly large and has marked effects on their efficiency. One mine superintendent estimated that each of his foreign miners consume an average of two quarts of beer a day, in addition to the whisky they drink. Another superintendent stated that each week a carload of beer and a barrel of whisky were shipped into his town of 1800 people, two-thirds of whom are recent immigrants. The statement which follows shows the amount of beer and whisky ordered during one week from beer agents in three typical mining towns:

WEEKLY CONSUMPTION OF BEER AND WHISKY

Town	Quarts of Beer		Quarts of Whisky	
	Gross	Per Cap.	Gross	Per Cap.
A ...	5,400	4.5	100	0.08
B ...	5,000	4.7	300	0.28
C ..	7,200	4.8	400	0.27
	17,600	4.7	800	0.21

In all three towns some limitation on sales was imposed, and the above quantities are only the restricted orders of the beer agents. Additional amounts were consumed at neighboring saloons or were carried into the towns by the men themselves. When it is remembered that the greater portion of these intoxicants was consumed by the more recent immigrants, some general idea of the amount consumed by each workman can be reached. It must be remembered that drinking is particularly heavy immediately after pay day, so that during this time the most marked effects on efficiency are to be expected. The following table shows the total amount of beer and whisky ordered in one Pennsylvania town during a period of ten weeks:

CONSUMPTION OF INTOXICANTS IN PENNSYLVANIA TOWN

Race	Beer		Whisky	
	Quarts Ordered, 10 Weeks	Quarts per Cap. per Week	Total Quarts Ordered 10 Weeks	Quarts per Cap. per Week
American	100	0.30	3	0.006
English	0	0.00	4	0.050
Irish	48	0.69	0	0.000
Total	148	0.30	7	0.010
Bohemian	720	3.79	0	0.000
Italian	1,792	4.17	48	0.112
Polish	12,656	4.28	190	0.064
Slovak	6,272	2.88	184	0.084
Totals and averages	21,440	3.72	422	0.073
Negro	192	1.20	0	0.000
Grand total and averages	21,780	3.30	429	0.065

In this town sales are restricted and the figures given above are 40 per cent. less than the amount formerly ordered when no restriction was practised. Here again actual consumption is larger, since much is consumed in saloons outside the town and also carried into the town by the mine workers. The tables plainly indicate that consumption is much greater among more recent immigrants than among the Americans and the older immigrants, since the former group ordered per capita more than twelve times as much beer as the latter, and about seven times as much whisky. These results are somewhat influenced by the fact that the proportion of single men to women and children is higher in the second group than in the first, but it is also due in part to the fact that the women and children in the second group are much larger consumers than those of the first group.

Drink Whisky Instead of Light Wines

Figures of liquor consumption in towns where no restriction is exercised were not obtainable, but in view of the fact that in the average mining town numerous beer and whisky agents are constantly soliciting orders, some idea of the general consumption in such towns can be formed from the preceding tables. The recent immigrants have been accustomed to drinking beer or light wines abroad. In this country, however, they drink whisky in place of light wines, and they drink to excess. This is due to several causes: (1) They "treat" according to the American custom; (2) they have little opportunity for decent amusements or to buy homes or property with their surplus money, and there is a disposition to spend money freely. Excessive drinking, particularly among the foreign workmen, lowers their efficiency to an appreciable degree. As already stated, this is more marked in the days immediately after pay day, when the drinking is especially heavy. There is usually a decreased number of men at work and a consequent falling off in the output of coal and coke. The general manager of one large company says that for the half week following "Pay Saturday" production shows a loss of approximately 20 per cent. Formerly this was often larger, until the company somewhat restricted the sale of intoxicants in its village. The following reports from two mines give a fair idea of the effects of drinking on production during the period immediately following pay days:

DAILY PRODUCTION AT MINE NO. 1

	Cars of Coal Produced
Normal	550
Saturday (pay day)	not running
Sunday	not running
Monday	390
Tuesday	430
Wednesday	460
Thursday	550

Normal thereafter till pay day.

At mine No. 2 the output was also lowered by the fact that Tuesday after pay day was a church holiday.

Not only are fewer men in the mine immediately after pay day, with consequent loss of output, but the companies suffer additional loss through increased medical and hospital equipment, more numerous accidents and consequent medical and hospital bills, and through reckless and careless mining, with the loss of more or less coal and time and labor. The life of the town and of the workmen is demoralized, and the industry is rendered more unattractive to the better and more ambitious workmen and their children.

DAILY PRODUCTION AT MINE NO. 2

	No. of Men	Tons of Coal Produced
Normal	415	2,550
Saturday (pay day)	(not running)	
Sunday	(not running)	
Monday	320	1,934
Tuesday	202	1,672
Wednesday	384	2,402
Thursday	403	2,532
Friday	436	2,600
Saturday	412	2,200
Monday	414	2,566

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

A decision has been handed down by the Interstate Commerce Commission in the case of the Missouri & Illinois Coal Co. vs. The Illinois Central R.R. Co. This case grew out of an embargo established last winter by the Illinois Central against the movement of coal from mines on its line in Illinois to points in Missouri. The railroad's defense was that if it allowed its cars to go on to the lines of the railroads in Missouri they would confiscate them, and that the Illinois Central would not have sufficient cars to conduct its own local business.

Opinion of Commission

In the opinion of the commission, which was written by Commissioner Franklin K. Lane, it is said:

"The commerce of the country is regarded by the act to regulate commerce as national, not local, and the railroads are required to serve the routes which they have established without respect to the fact that this may carry their equipment beyond their own lines. The temporary confiscation by carriers of the cars of other railroads and the placing of embargoes against cars being sent off of the lines of the owners are alike unlawful. An embargo may be justifiable because of the physical inability of the carrier for some reason to deal with traffic which overwhelms it, but an embargo placed against connecting carriers because of their failure to promptly return cars is not consonant with the service which the carriers constituting the through route are required by law to give. By the act to regulate commerce the railroads are required to make reasonable rules and regulations with respect to the exchange, interchange and return of cars used upon through routes, and where they have failed in this respect the commission is empowered to determine the individual or joint regulation or practice that is just and reasonable."

Merits of the Case

Commissioner Lane further says: "Instead of an orderly system of car interchange carried out in good faith, we find in this case one road stealing the equipment of its connection by way of reprisal against similar thefts of which it is the victim. The result is that the coal company in Illinois, which has undertaken by contract to serve industries in Missouri, is cut off from its market by reason of the closing of the route which the law requires the Illinois Central and the Missouri Pacific to maintain and keep open.

"The complainant here was entitled at all times to send its coal to points upon the Missouri Pacific and through other connections at St. Louis to points upon their lines. It is not an adequate defense for the Illinois Central to say that this route was closed because of the dishonorable conduct of its connections. The burden rests upon these carriers to keep their highway between the mine in Illinois and the factory in Missouri open and to devise some method by which this can be done. The coal mine is entitled under the law to rely upon the carrier maintaining its route irrespective of the unfriendly relations that may exist between the carriers. The commerce of this country cannot be conducted under a system of railroad operation based upon such primitive practices of warfare as reprisal and embargo. Such methods are not the expression of civilization which leads to order, system and certainty, but are the loose and archaic methods of a disorganized industrial system."

Under this decision all of the car *per diem* and car-interchange rules of the American Railway Association become subject to the regulation of the Interstate Commerce Commission. This is the first time that the commission has taken this position which is based upon the Mann-Elkins Bill of 1910.

For Government Coal Mines

Representative Lafferty has offered a bill for extending the jurisdiction of the Interstate Commerce Commission over railroads in Alaska and for other purposes. The opening of the bill provides "that the Secretary of War, under the direction of the President, proceed to open and mine, at the best and most available point, coal of the best quality there to be obtained on the public lands of the United States, in what is commonly known as the Bering River coal fields in Alaska."

Sections 5 and 6 of the bill provide for the construction of a railroad and boat line to tap the fields and the disposal of the coal thus mined and transported to fill the various needs of the government.

Provision is also made for the sale of any surplus coal which may remain after governmental requirements are satisfied, as follows: "In addition to supplying the government needs coal shall be sold commercially to any persons desiring to buy the same from said government mines, and the price charged therefor shall not be in excess of the cost of mining the same and 4 per cent. per annum revenue on the sums expended therein by the government; that said boat line and railroad shall be open to all persons alike, as common carriers of freight and passengers, at charges therefor to be fixed by the Secretary of War, which shall not be in excess of the cost of operating and maintaining the same, and sufficient to yield a revenue of 4 per cent. per annum on the amount expended therein by the government."

Alabama

Birmingham—In a statement authorized by William H. Skaggs, of Chicago, it is said that the construction of the Gulf & Northwestern R.R. From Tuscaloosa, to Natural Bridge, Ala., will be started not later than Apr. 1, 1912. The purpose of this road is to develop about 40,000 acres of coal land in Tuscaloosa and Fayette Counties.

The Tennessee Coal, Iron & Railroad Co. will discontinue the working of state convicts in its coal mines, upon the expiration of its present contract with the state, Jan. 1, 1912.

Montgomery—The stockholders of the Sheffield Land, Iron & Coal Co. met Dec. 2, for the purpose of increasing the capital stock from $860,000 to $1,000,000.

California

Los Molinos—It is reported that a ledge of good coal has been discovered in Deer Creek Cañon, about 20 miles east of Vina. Indications are, however, that the seam is not more than 2 ft. thick.

Colorado

Denver—The strike situation in the northern Colorado coal field continues unrelieved, although no further violence has been reported. Governor Shafroth's efforts to effect an agreement have been unavailing and the prospect of a settlement is not near. Federal intervention is not expected. About 1000 union men are still on strike, although the mines are being operated and approximately 2000 men employed.

Fort Collins—It is reported that Larimer County will soon have a coal mine in full operation. The Fort Collins Coal Mining Co. has located a 5-ft. seam of bituminous coal at a depth of 350 ft. and a second seam 5½ ft. in thickness at a depth of 450 ft. The property lies near Wellington and the company feels assured of possessing two beds of coal a mile long and a half mile wide.

Title to thousands of acres of coal lands in Colorado, particularly in Routt County and in the vicinity of Walsenburg, may possibly be involved as the result of a decision just handed down by the United States district court in the case of the government against the Diamond Coal & Land Co., of Wyoming. The appellate court holds that title to coal lands may be proved by expert geological tests that coal deposits lie under the surface regardless of whether or not any outcroppings appear on the surface. The decision is likely to result in government suits to regain possession of several thousand acres of coal lands in this state.

Illinois

Frankfort—Official announcement has been made of the extension of the Burlington's southern Illinois coal line into the heart of the Franklin County coalfield. The extension will branch off from the main line, south of Christopher, and extend in a southeasterly direction for six miles to West Frankfort. Practically all the right of way has been secured and the work of construction will start early this month.

Chicago—Bituminous coal operators of nine States met at the Hotel La Salle, Dec. 4, and formed a temporary organization, the object of which is to prepare for the expiration of the present wage agreement so that the industry may be protected. Another meeting will be held Dec. 18, when the committee on organization will report and the new association be made permanent. The States represented are Illinois, Indiana, Iowa, Missouri, Kansas, Oklahoma, Arkansas, by delegates appointed by the operators' associations of those States, and Montana and Wyoming by individual operators.

The United Mine Workers of America, have issued a call for a joint meeting with operators of the competitive field—Indiana, Ohio, Pennsylvania and Illinois—to be held in Chicago. It is said, they wish to present to the operators, a demand for a new wage scale, probably 5c. a ton in excess of the present rate.

Indiana

Terre Haute—The Miami Coal Mining Co., with principal offices in Terre Haute, has filed a mortgage of $150,000 to cover all the mining property belonging to the company located in Vigo and Vermillion Counties.

Brazil—The Schlatter Coal Mining Co., operating in the block-coal district, about one mile south of Brazil, has purchased the Treager Coal Co.'s No. 2 mine, and has begun improving the property.

T. M. Honan, attorney-general for Indiana, has given an opinion to Frank I. Pearce, head of the mine-inspection department of the state bureau of inspection, in which he says members of a board of mine examiners cannot issue certificates pending the next regular meeting of the board. A miner failing to present himself for examination on the first Wednesday of any month shall not be permitted to work in a mine on a temporary permit until the next regular meeting of the board.

Iowa

Des Moines—The Rock Island Co. has commenced shaft sinking in the new coal field controlled by it and extending from a point 12 miles southeast of the city for a distance of eight miles. Two large shafts are being developed which will be ready about July 1, upon the completion of the southwest line. The mines will be electrically equipped and will give employment to about 1200 to 1400 miners. Des Moines will be the market town for these mines. An electric plant will be built at the Dallas shaft, which will not only generate sufficient power for the mine purposes, but a surplus for a couple of local industries and for lighting in Dallas. The intention now is to devote the entire output of the mines to the coaling of the Rock Island road and not to engage in the commercial trade.

Kansas

Pittsburg—It is stated that on Jan. 1, one-third of the Kansas coal mines will be shut down indefinitely. On that date the act of the last legislature goes into operation providing for workingmen's compensation. The mine operators are quoted as saying that "they cannot afford to take the risk of liability to injured employees necessitated by the law." Consequently a large number of the mines will suspend.

Kentucky

Whitesburg—The Kentucky River Consolidated Coal Co., composed of eastern capitalists, owning some 50,000 acres of choice coal and timber lands in southern Letcher and Perry counties, along the line of the Lexington & Eastern R.R., make the announcement that they will soon take steps looking to the development of their property. It will be necessary to build spurs out from the Lexington & Eastern R.R. to reach the property.

Owensboro—A voluntary petition in bankruptcy has been filed here by the Dovey Coal Co. of Mercer, Muhlenberg County, showing its liabilities to be $116,000 and its assets as aggregating $150,000. Among the assets are 825 acres of mineral land.

Winchester—The Lexington & Eastern engineers are locating a branch line of railroad from the mouth of Boone's Fork, up the Kentucky River to Moore's branch, in a rich coal and timber district, the property of the Mineral Development Co., a Philadelphia corporation. It is understood that the construction of this branch will be started within the next month or so. Another near-by branch is to be built up Potter's Fork of Boone, and still another up Yount's Fork of Boone.

Barbourville—The Brush Creek Coal and Manufacturing Company will be shipping coal within 30 days from its large mine at Jones Trestle, on the Cumberland railroad. The mine is in the famous Dean seam, which measures 7 ft. of clean coal and is considered the best domestic fuel in the field. The company is now considering a proposition from a Louisville concern, offering to take over the entire output of this mine for a period of years.

Michigan

Bay City—The Buena Vista Coal Co., of Saginaw County, has been thrown into bankruptcy by some of its creditors. It is represented that the mine is abandoned and partially filled with water, and the machinery, as well as the property in general, is going to waste.

Missouri

St. Louis—The Egyptian Coal Mining Co., composed mostly of business men of Marissa, Ill., has petitioned for articles of incorporation. The company has a capital stock of $65,000, of which $45,000 is paid up.

St. Joseph—A 2-ft. vein of coal which has been discovered 1½ miles southeast of Halls, bids fair to yield an abundance of coal equal to the Richmond variety. It contains practically no slate and gives an intense heat.

Ohio

Columbus—The Biwabik Mining Co., of Youngstown, was incorporated recently with a capitalization of $600,000.

It is practically certain that Ohio will not be represented in an association of coal operators of Ohio, Illinois, Indiana and western Pennsylvania, which was advocated by Pres. John P. White, of the United Mine Workers of America in a letter read before the Hocking Valley coal operators at a recent meeting. It is understood that Ohio and western Pennsylvania will attempt to fix a wage scale

next year, independent of the districts whose conditions are regarded as too nearly individual to conform with Eastern needs.

Dayton—The W. K. Steele Coal Co. has been incorporated with a capital stock of $50,000 to mine and sell coal.

Pennsylvania

Bituminous

Pittsburg—The Walton mine No. 2, of the Monongahela River Consolidated Coal & Coke Co., two miles south of Elizabeth, which has been idle for six months, has resumed operation. It is expected that the work will continue for some time. Recently the company extended the main heading into the 400 acres of adjacent coal land owned by the Hillside Coal Co., which was absorbed by the River combine at the time of its organization, and which adjoins the Walton mine. This is the coal to be extracted. The old mine will form a lead for the coal and will be used exclusively for river shipment. About 300 miners will be given employment.

The Merchants' Coal Company of Boswell, which is owned by the United Coal Company, of Pittsburg, is making preparations to place in operation its new fan, which has been constructed at considerable expense. The fan is part of projected and completed improvements there that will cost in the neighborhood of $180,000. When the improvements have been completed, the company expects to be in a position to double its output, which at present is from 2000 to 2500 tons per day.

The H. C. Frick Company is erecting a wash house for the use of the miners at its Collier works, Fairchance, Penn.

Connellsville—Among important trade developments is the recent placing of contracts for furnace coke, aggregating 1,400,000 tons, for delivery during 1912.

Altoona—The Kelso Smokeless Coal Co. has resumed shipping from its mines near Hogback, after a suspension of three years. The plant is one of the Huff-Keystone properties. About 500 men will be employed when the operation gets well underway.

The Pennsylvania Central Light and Power Company, of Altoona, is rushing to completion the construction work on a power line into northern Cambria county, where it expects to supply several operations of the Pennsylvania Coal and Coke Corporation, as well as a number of other mines.

Brownsville—A new concrete pump house is being built at the Naomi Coal Company's mine at Belle Vernon to replace the one destroyed by fire some time ago.

Reynoldsville—A force of men has been at work erecting new power buildings for the McKnight Coal Co. on its property here, and good progress is being made. The tipple has been remodeled and the new boilers are already on the ground.

Anthracite

Hazleton—After a year and a half of prospecting, the Penn Forest Coal Co., composed of Philadelphia capitalists, has discovered coal on the Penrose estate, between Hazleton and Weatherly, in a section where it was not thought anthracite would be found.

This news is confirmed by H. George Stimson, of Philadelphia, secretary of the corporation, who has charge of the work. The vein approximates 12 ft. thick, according to Mr. Stimson, and the tract contains about 10,000,000 tons of coal. The company has leased the entire 600 acres of the Penrose estate for 40 years, and is making preparations for the development of the basin. The tract is east of Hazleton, between the Beaver Meadow and Eckley basins.

The Penn Forest Coal Co. has sunk a shaft, and it is expected that a breaker will be constructed in time to mine and ship coal by Apr. 1, 1912.

Pottsville—Owing to the demand for washery sizes of anthracite, the Philadelphia & Reading Coal & Iron Co.'s officials gave orders, Dec. 6, that the Anchor washery, at Heckscherville, which was burned, probably by incendiary origin, entailing a loss of $10,000, is to be rebuilt. Work has been started and a sufficient force has been employed to guarantee that the new washery will be ready to resume within six weeks.

Scranton—James G. Shepherd has leased to the People's Coal Co., of this city, the right to mine the coal under six tracts in West Scranton. By the terms of the lease, the reorganized company is to pay Mr. Shepherd a royalty of 32c. per long ton on all coal above pea size; 16c. a long ton on pea coal, and 8c. a long ton on all sizes under pea coal.

Tennessee

Knoxville—An explosion took place in the Cross Mountain mines at Briceville, near here, in the morning of Dec. 9, shortly after the men had entered for work. According to newspaper reports about 100 men were entombed. Up until the night of Dec. 12, five men had been taken out alive and 31 bodies recovered. The mines belong to the Knoxville Iron Co., and no effort is being spared in the work of recovery. Several mine-rescue cars were immediately dispatched to Briceville.

It is reported that the extensive holdings of the King Mountain Coal Co. on the Clearfork extension of the Southern Ry. Co., west of Jellico, are about to be taken over by a party of Ohio capitalists. Should this deal be made, it will result in the development of the property involved and will mean much for the Jelico coal-mining section.

Washington

Spokane—The Western Fuel Dealers Association, which recently held a meeting here has joined with the National Federation of Retail Merchants. The decision to do this came at the third annual convention and banquet of the local association last week. The vote was taken after a speech by A. L. Porter, one of the organizers of the association, at Chicago, some weeks ago.

West Virginia

Fairmont—The West Virginia Mining Institute concluded its semi-annual session here Dec. 6, after electing the following officers: President, Frank Haas, Fairmont; vice-presidents, Neil Robinson, Charleston, George T. Watson, Fairmont, John Laing, Charleston, R. S. Ord, Maybury, J. F. Healy, Elkins; secretary-treasurer, E. B. Day, Pittsburg. The next meeting will be held in Charleston.

Williamson.—A coal deal has been completed here that involves the transfer of 665 acres of coal land on Gilbert's Creek, at an average price of $50 per acre. E. E. Musick and R. W. Buskirk disposed of the property to George Buskirk.

Wheeling.—It is reported that the Wheeling Coal and Coke Co. is endeavoring to secure control of the leasehold rights of the Panama Coal Co., a Marshall County concern which is now in the hands of a receiver.

Canada

British Columbia—The British Columbia Coal & Coke Co. is opening up a 15-ft. seam of coal on its property at Coalmont, B. C. The vein was cut by a tunnel 2200 ft. long. Overlying this seam are five others which will eventually be tapped by an extension of the same tunnel. The management expects to be shipping 500 tons daily by May 1. The railroad track has been extended to the mine and a tipple and other machinery will be installed forthwith.

The Brandon, Manitoba, board of trade has passed a resolution petitioning the minister of customs that the tariff of 50c. on United States soft coal, remitted in September, be not reimposed this winter, owing to the poor coal supply in Western Canada at present, due to the recent strike.

Col. Dennison, the United States consul, at Fernie, B. C., reports that the following mines have cleared shipments through the office at Fernie and most of the mines are increasing their output: Canadian Consolidated mines, at Frank; Hillcrest mines; Davenport Coal Co.; West Canadian collieries; Leitch collieries; Maple Leaf and McGilvray Creek mines, and the Corbin mines. The coke ovens are being charged and shipments to the smelters will commence soon.

Personals

W. H. McIntyre, formerly 4th vice-president, Equitable Life Assurance Society, is now 1st vice-president and general manager of Manning, Maxwell & Moore, Inc.

C. C. Bunton has been appointed manager of transportation of the Monongahela River Consolidated Coal & Coke Co., and will assume the duties of this office at once.

R. Y. Williams, government mining engineer, with headquarters in Urbana, Ill., delivered an interesting illustrated address on the work of the bureau of mines before the Science Club, Terre Haute, Dec. 7.

Edward T. Penrose, general manager for the Penn Central Light, Heat & Power Co., Altoona, Penn., has tendered his resignation to become general electrical engineer for the Pennsylvania Coal & Coke Co.

Charles H. Rowland has been elected president of the Moshannon Coal Mining Co., with operations in central Pennsylvania. Other officers are: Vice-president, John G. Anderson; and manager, A. S. Brown.

Monks & Johnson, architects and engineers, Boston, Mass., have associated themselves with Henry F. Keyes, architect, Boston, for the preparation of plans and specifications for certain large industrial developments.

C. H. Nesbitt, chief mine inspector for Alabama, has been instructed by Governor O'Neil to appoint a committee of three, with himself as chairman, to report on the contract between the state and the Pratt Consolidated Coal Co., covering the operation of the Banner mine with state convicts, and also to report on the matter of a proper cost for mining coal at that operation.

George W. Theiss, vice-president and a director of the Monongahela River Consolidated Coal & Coke Co., has tendered his resignation, to take effect Jan. 1, 1912. Mr. Theiss has been actively identified with the river coal trade for the past 22 years. W. H. Crump, master of transportation, and Capt. John Moren, manager of the freight department, a director and one of the company's organizers, have also resigned.

Walter B. Snow announces the recent addition to his staff of Sidney G. Koon, M. M. E., for four years editor of *International Marine Engineering*, and later metallurgist, Jones & Laughlin Steel Company; and also the addition some time since of John S. Nicholl, B. S., lately with the New York Edison Company, and formerly acting manager for F. W. Horne, importer American machinery, Yokohama, Japan. Both are members of the American Society of Mechanical Engineers.

Obituary

Amos H. Woodruff, 76 years old, retired mine operator and wholesale coal dealer of Chicago, died Dec. 3, of pneumonia while visiting friends in Seattle, Wash. Mr. Woodruff had lived in Chicago 35 years.

Capt. Winfield Scott Carr, aged 63, for many years official coal gauger at the river front and well known by river men from Pittsburg to New Orleans, died at his home in Cincinnati, Ohio, Dec. 4. The captain before he retired from active service about six years ago owned the steamer "Sentinel," which he used in his occupation as coal gauger.

James A. Milholland died at Glenover, Md., Dec. 7, aged 69 years. He was born and brought up at Reading, Penn., where his father was head of the mechanical department of the Philadelphia & Reading R.R., and the inventor of many improvements in the early days of the locomotive. Later he went to Cumberland, Md., where he passed the rest of his life. He was for a number of years vice-president of the Consolidation Coal Co. and president of the Georges Creek & Cumberland Railroad.

New Publications

Labor Legislation Enacted by the Forty-seventh General Assembly of Illinois. Boards, 142 pp., 6x8¾ in., Bureau of Labor Statistics, Springfield, Ill.

Topographic Maps and Folios and Geologic Folios. Index to about 2000 maps and folios which may be secured from the Director, U. S. Geological Survey, Washington, D. C. Paper, 112 pp., 6x9 inches.

Quarterly of the Colorado School of Mines for July and October, 1911. The latter number contains articles on the scope and progress of the mining industry in Colorado, prepared by the Colorado School of Mines. Paper, 6x9 inches.

The Twentieth Annual Report of the Mining Department, State of Tennessee. R. A. Shiflett, chief mine inspector. Boards, 155 pp., 6x9 in. This report is for the year 1910, and is the same in arrangement and scope as those previously published since 1903.

Trade Publications

H. K. Porter Co., Pittsburg, Penn. Steam, Compressed-air and Gasoline Locomotives. Four-page announcement, illustrated.

Robins Conveying Belt Co., New York, N. Y. Bulletin No. 47. Belt Conveyors and the Robins-Messiter Patented Ore-Bedding and Reclaiming System. Illustrated, 30 pp., 6x9 in.

Keystone Driller Co., Beaver Falls, Penn. Booklet, "The Rescue of Joseph Clarey from the White Oak Mine." 16 pp., illustrated. This publication deals with the use of cable drills in rescuing entombed miners from shaft and drift workings.

Industrial Notes

The Durham Coal & Iron Co., of Chattanooga, Tenn., contemplates increasing the capacity of its mines and is considering the installation of a byproduct coking plant. C. H. Smith is vice-president and general manager.

T. J. Asher, Wasioto, Ky., will make the purchases of machinery for the Southern Mining Co., Williamsburg, Ky., which recently organized for the purpose of developing coal lands in eastern Kentucky. Fifteen electric mine locomotives, 12 longwall machines, two coal washers and other special equipment will be needed.

The H. K. Porter Co., of Pittsburg, Penn., well known manufacturers of light locomotives which are extensively used in connection with mining work, announces that it has gone into the manufacture of large and heavy locomotives and gasoline locomotives in addition to the smaller types which have been built by it for the past 45 years. The gasoline locomotive is this company's latest specialty.

The Nellie Coal Co.'s mine at Argentine, Penn., has resumed work with a new tipple, boiler house and shop and a newly equipped engine room. Among other labor-saving devices in the tipple is a Phillips patent automatic dump. An innovation for this district is to be introduced at the Nellie operation in the form of a gas-driven locomotive for hauling coal in the mine. The company has contracted with the Milwaukee Locomotive Manufacturing Co. for one of these locomotives which from present appearances are going to become a popular form of mechanical haulage. The Grove City Machine & Supply Co. furnished the boilers, engines and other machinery.

For some time the Hyatt Roller Bearing Co. has made a practice of issuing bulletins covering in detail the ratings and capacities, indicated uses and actual application of its flexible roller bearings. Separate issues cover the different types such as the Long series for machine tools and similar work, and the Short series for shafting boxes and for special work in cars used in the transportation of passengers, freight and mine products. Forms for the entry of questions or specifications are also provided and with the carefully arranged tables in the bulletins make it easy to procure the proper bearing for the particular purpose. These bulletins are at the call of anyone interested and form a collection of special information worthy of a place in any engineering office.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

With a few exceptions, the general trend of the market during the past week has been backward. Indications that such would be the case were evident last week and the continued mild weather has brought the realization. This applies more particularly to domestic, steam and slack continuing strong.

On the Atlantic Coast, a perceptible falling off in trade, especially in anthracite, has given the dealers a welcome opportunity to catch up. This is particularly so in the retail trade, the effects of the weather not yet being felt by the wholesalers. Coastwise movements are much better and prices are variously reported as the same or lower, with the exception of slack, the demand for which is heavy.

Loading at lake ports, for storage over winter, still continues in Ohio and some shipments are being made without insurance. The weather has been mild and the condition of the retail trade is not satisfactory, although prices are steady. There appears to be a large over-production for which the strike scare or continued low temperatures are the only apparent remedy.

At Chicago and throughout the Middle West the weather and a large car supply has weakened the market appreciably. Prices are unusually low and trade is reported the worst for several months. As compared with previous seasons the market is said to be in the poorest condition for a number of years.

In the extreme West trade is reported active with prices firm and supplies good.

Boston, Mass.

The mild weather last week somewhat relieved the tension. The movement of tonnage is better, but rates are still at the high point reached a fortnight or so ago, and recovery from the shortage of bottoms is sure to be slow. Prices are practically unchanged, \$2.60 still being the firm figure, f.o.b., for Pocahontas and New River, and around \$4 continues to be the price on cars, Boston, for the same grades.

Georges Creek shipments are coming through with noticeable regularity, and the shippers of that variety are about the only ones in shape to sell spot cargoes. Their contract obligations are evidently well in hand, and there is not likely to be much shortage in that quarter.

Pennsylvania bituminous coals are cutting very little figure now. With the advanced freight rate from Philadelphia, the urgent request for anthracite and the shortage of barges, almost nothing is heard of any call for hatch-load shipment. It has sloped off considerably.

The anthracite market is still way behind on shipments. Orders filed five and six weeks ago are in some cases unfilled, egg and broken being the only sizes in supply, while the call is almost exclusively for stove, chestnut and pea. The falling off in retail trade for a few days will give the dealers breathing space.

Marine freights are still quoted on the basis of \$1.20@1.25 for large vessels, Hampton Roads to Boston.

New York

Additional improvement is noted in the bituminous market at New York. Contract demand is steady and in many instances shippers, especially those producing the fancy grades, are having all they can do to take care of regular business. Some new business is coming into the market and even the low-grade steam coals are now finding a better demand.

The snow storm early last week had an effect on railroad transportation, and at the New York piers winter conditions are beginning to prevail. The yards have been congested with heavy accumulations, and there has been more or less delay in loading. The general embargo that was placed on the South Amboy piers last week, to relieve congestion there, has been removed and shipments again resumed. Some of the shippers to this pier who had ready disposition for their stocks at the piers, and who were not responsible for any of the accumulation, now find themselves short of coal pending the arrival of shipments made since the resumption.

The weather has been a little more favorable this week for the movement of tows on the Sound, but marine freight rates are still firm and boats for the Eastern trade extremely scarce. Harbor boats are also short and the congestion and delay at the piers makes the shortage more pronounced.

Notwithstanding the steady condition of the demand, prices at which steam coals are being offered, f.o.b. New York, have shown but little tendency to advance although they are somewhat firmer. Quotations range about the same as previously reported.

Philadelphia, Penn.

The present week started in with unusually mild weather, and as a consequence there has been a perceptible falling off in the demand for retail coal. Egg is particularly slow in movement, while stove, chestnut and pea are fairly active, but the dealers declare it will require some good, cold weather to create an active market. However, the weather man has promised some colder weather, which should act as a spur to promote a better feeling in the anthracite trade.

The excitement incidental to the proposed advance in prices has disappeared, and the public have resigned themselves to pay whatever prices the coal dealer may ask. It is not believed, however, that many of the dealers are realizing the new prices. As one dealer sets forth in his advertisement: "Old prices for cash or C. O. D., book accounts 25c. additional." With the trade as stagnant as at present, they are probably willing to accept the old prices, cash or credit.

The wholesale market still enjoys its season of prosperity, the condition of the retail market not as yet having reached the producer. The tidewater business is splendid, although this applies more particularly to orders already accepted than on new business being received.

A prominent feature of the market is the call for vessels for Southern shipment, of which there does not seem to be a large supply. Freights are quoted anywhere from \$1.25 to \$1.59, where 90c. to \$1.25 was the case a month or six weeks ago. This is getting to be quite serious, as many inquiries are coming from the South, indicating a possible shortage in anthracite.

Pittsburg

Bituminous—Domestic demand continues good, and manufacturing is fair, with a good demand for slack, which continues to stiffen. Some of the mines which engaged largely in the lake trade accumulated large piles of slack in the summer, and this product has prevented an advance in slack to the full schedule price, which is assumed to be 75c. We quote prices unchanged, except slack, which is 10c. higher: Nut, \$1@1.05; mine-run, \$1.05@1.10; ¾-in., \$1.15@1.20; 1¼-in., \$1.25@1.30; slack 65@75c.; all prices per ton at mine, Pittsburg district.

Connellsville Coke—An interesting feature in the market is an advance of

10c. a ton in prompt furnace coke, to a minimum of $1.60, after the market had held at $1.50 for many weeks. An advance usually occurs about this time in prompt furnace, owing to furnaces calling for extra coke to guard against interruptions in shipments, both through weather conditions affecting the railroad movement and the holiday season at the ovens reducing production.

For a long time there has been only a very limited supply of prompt coke on the market, production being very closely adjusted to shipments on contracts, and it only required a slight extra demand to send prices upward. Last week we noted sales at both $1.50 and $1.55, and since then additional sales have been made at that price, while late last week sales of 50 to 75 cars were made at $1.60. Several contracts are understood to have been practically closed for next year since those reported a week ago, but details are not divulged.

The contract market is stiffer, nearly all the coke available at prices quoted being closed. As there is little more to be covered, the market is not quotably changed, and we repeat last week's quotations, except for the advance in spot furnace: Spot furnace, $1.60@1.65; contract furnace, first half, $1.60@1.65; year 1912, $1.65@1.75; prompt foundry, $1.80@1.90; contract foundry, $2@2.25.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Dec. 2 at 315,931 tons, a decrease of 15,000 tons, and shipments at 3551 cars to Pittsburg, 4969 cars to points west and 932 cars to points east, a total of 9452 cars, which is a decrease of 169.

Baltimore, Md.

There was no noticeable change in the Baltimore market during the past week, and the trade here is apparently marking time. One of the largest operating companies in Baltimore reported an increase in inquiries, and slightly heavier spot orders, but this improvement does not apply to the market as a whole. A majority of operators state that conditions are in about the same shape as during the week previous. Some little disappointment was expressed over the failure of the numerous inquiries, reported last week, to develop into actual business. Some did, but they were not sufficient to materially affect conditions.

Most of the coal moved out of this market during the week just ended was delivered under existing contracts. Spot business, for the most part, was entirely absent. The operators delivering under contract are confronted with higher vessel rates, which, if continued for any length of time, will prove rather serious.

The low grades of coal are being quoted at 75c. and 80c. per ton, while the better grades can be purchased around $1.10 and $1.25 per ton. Big Vein, Georges Creek coal, is quoted at $1.60 per ton.

From the latest reports received, car movements on all the railroads, moving coal shipped by Baltimore companies, were good during the week.

Buffalo, N. Y.

The general trade in coal was becoming good, with anthracite mostly rushing, when the weather turned warm and the market suffered severely. While the demand for anthracite is most affected by the weather, there is a decided falling off in bituminous.

But for the steady improvement of slack, which has not been entirely suspended by the warm spell, the handlers of bituminous would be in despair. Some of them are even now inclined to say that there is little encouragement offered on the part of the consumer and it may be as well to let matters take their own course till cold, or at least seasonable, weather returns.

The worst of it is there are reports of large offers at cut prices. One jobber states he was offered a lot of coal at such low prices that he felt obliged to take ten cars or go out of the business.

There is, otherwise, a better tone to the bituminous trade, if only on the report that pig iron is selling more actively than through the summer. Business men claim not to see why this is so, but if it continues there will soon be much less complaint of slow trade all along the line, for, of course, iron controls the situation.

The close of the lake trade has been quite reluctant on the part of all shippers. October and November were stormy and there has been much less business done by water than was planned, even though the weather has not been so cold as usual. The arrival of December found all branches of the lake trade away behind the estimates.

Bituminous prices remain at $2.50 for Pittsburg three-quarters, $2.40 for mine-run and $2 for slack, freight included, with Allegheny Valley about 20c. lower. Coke is a trifle firmer at $4.25 for Connellsville and $3.50 for stock, including freight. The anthracite trade has dropped off very decidedly since the warm weather set in, but the shippers were generally supplied with orders enough to keep them busy.

Cleveland, Ohio

A number of boats have been loaded in the past week for lake coal to be held over during the winter, and in consequence, slack has been plentiful with prices firm.

The domestic trade, owing to the mild weather in the past ten days, has not been as good as the week previous, and no change has taken place in the steam-trade condition. Taking all in consideration, the coal business in Cleveland is anything but satisfactory, excepting in slack coal, which seems to be in abundance and prices held firm.

There is a general impression among the coal men that things will improve after Jan. 1.

Columbus, Ohio

Warmer weather and the approach of the holiday season has had the effect of quieting the coal trade in Ohio fields during the past week. Prices have not suffered in the least and the consensus of opinion is that the lull is only temporary and that trade will improve after the first of the year.

One of the best features of the market is the tendency on the part of some of the railroad systems and larger manufacturing establishments to store in anticipation of a suspension at the expiration of the present wage agreement between the operators and miners, Apr. 1.

Prices have ruled firm during the past week, despite the unfavorable weather conditions. The steam grades are firm and the requisitions of larger users are about the same as usual. There is more strength shown in the fine-coal market, owing to the fact that the lake trade is a thing of the past.

Operations in Ohio fields have been quite active during the week, in spite of the weather conditions. In the Hocking Valley the output is estimated at 85 per cent. of the capacity and the same percentage maintains in the Jackson, Cambridge, Pomeroy Bend and Crooksville fields. In eastern Ohio the output was not quite so large, but still was satisfactory.

Retail trade has been a little slow, owing to the higher temperatures and the bad roads in the rural sections of the state. Then, again, the larger consumers have stocked up for the winter and second orders will not be the rule for some time. There is little or no trouble from a car shortage, and operators and jobbers are able to keep well up on orders. The closing of the lake season released a large number of cars, which are now used in the domestic trade. Deliveries in retail trade have been interfered with by the icy streets and the mud. Prices are firm at the figures prevailing for some time, which are as follows:

Fancy grades of domestic lump	$1.75@2.30
Domestic lump in the Hocking Valley	1.50
Domestic lump in Pomeroy Bend district	1.60@1.75
¾-in.	1.35
Nut	1.15
Mine-run in the Hocking Valley	1.05@1.15
Mine-run in eastern Ohio	0.95@1.00
Coarse slack	0.30@0.40
Nut, pea and slack	0.40@0.50

Cincinnati, Ohio

The demand for domestic fuel has fallen off because there have been several days of unseasonably warm weather.

The demand for steam fuel is about the same, with a slight increase noted in fine coal. This is encouraging and most fortunate as it gives this market an opportunity to get back to something like its former firmness. For several months it has been sagging and there has constantly been a large amount of coal on track on consignment. A part of this has been sent to northern markets, which are demanding an unusual amount of that fuel.

The lump demand has been good for several weeks but the first touch of continued warm weather resulted in every office receiving wire requests to hold back shipments. Nothing but weather can have any effect upon the market before the first of the year—excepting, of course, a complete tie-up of cars.

The question of new labor contracts is one that is causing discussion and much serious thought. Both sides are firm in their stand that neither can give anything more and each believes that the other must yield.

Charleston, W. Va.

It cannot be said that present conditions are favorable to the operators, but there will be some relief after the first of the year. Prices in some districts where competition is keen are so low that it is only a question of time when the mines will have to cease operation if they desire to make ends meet. The conditions are more serious in the Kanawha territory than in any other. There run-of-mine gas is bringing 73c.; splint run-of-mine, 85c., and lump from $1.05 to $1.25. In competition with the Kanawha field is the Kentucky district, as well as Ohio and Tennessee.

Conditions in the New River district and the Pocahontas are not so bad. In the former, run-of-mine is bringing $1.10 and egg and lump from $2.25 to $2.50. The price of tidewater at the mines is $1.10 gross, but there is a strong belief that this will be increased to $1.20 after the first of the year. There is a probability that Kanawha district coal will also receive a little increase—a thing that is absolutely necessary if operations are to continue. It is freely admitted that coal cannot be mined for 73c. a ton.

The output for the last half of the present calendar year will probably be almost double that of the first, showing that production has been good during the last five months. The indications are that the output for the state during the fiscal year ending next July will show an increase of a million or more tons above that for the same period last year, when the production was about 60,500,000 tons.

Louisville, Ky.

The coal situation in Louisville remains much the same as last week, with plenty of river coal, due to a good boating stage, and the Kentucky product being shipped in, in quantities sufficient to supply all demands. In fact, the operators are not selling as readily as they would like. This may be due to the weather conditions, a decided rise in temperature materially affecting the demand.

The prices for Pittsburg, Jellico, Miller's Creek and other leaders have fluctuated but little in the past two weeks. The chances are there will be little change before March, when the quotations will fall materially. At the offices of the wholesalers here the statement is made that the falling off in demand by the consumers is having a natural effect on the shipments from the mines. The dealers, both wholesalers and retailers, agree that business now, as compared with this season last year, shows a falling off.

Olive Hill lump is being quoted at retail at $4; Pittsburg at $3.50@3.75 for lump, and $3.25 for nut; Jellico at $3.60; Kentucky lump at $3.25; Straight Creek at $3.75; St. Bernard at $3.25; Pocahontas lump at $4.75, and Gem at $3.

Nashville, Tenn.

A week of warm weather has hurt the coal market in this field as it always does, and has not helped to maintain the price of $1.50 on lump coal which the operators are trying to get from now on.

There has been little life to our market in the west Kentucky field during this season. Prices have not been satisfactory, and though most of the operators have been fairly busy during the few cool spells which only lasted for a day or two, the warm weather finds most of them without business.

It is a recognized fact, and has been for sometime, that there is a vast over production of coal in the west Kentucky field on the Louisville & Nashville R.R., for the markets which this coal can enter.

Prices on screenings and steam coal have not advanced and business is quite dull in that line. The prices which are supposed to prevail at present are as follows per ton:

Lump	$1.50
Nut	1.10
Mine-run	1.00
Screenings	0.35

These are the prices which the operators are endeavoring to maintain, but unfortunately they are having a hard time in doing so.

Indianapolis

There is little doubt but this has been the poorest season the Indiana coal fields have seen for several years, and both the operators and the miners are affected by the lack of steady work in the mines. No reason can be assigned except that factories are not demanding as much coal as usual and the weather conditions have been adverse for an active domestic consumption.

A prominent block-coal operator in the Clay County field said that at this time last year he was forty cars behind in his orders and did not catch up until the first of January, when the bottom dropped out of the market and the demand has not since been reëstablished. At this time of the year, the operators say, the demand should be twice or three times what it is now.

Chicago

Warmer weather has had a weakening influence on prices in the Chicago coal market. The close of navigation and an increase in the car supply also have been factors in lessening the strong upward trend heretofore prevailing.

Some of the large dealers in smokeless are selling it at $1 flat, although $1.10 is being obtained in many cases. Smokeless lump and egg, as a rule, command $2, the $2.25 price prevailing only in a few instances. The market for screenings remains practically unchanged. There has been an increase in the car supply for handling anthracite shipments, but a decrease in the volume of buying has been noticeable. There is a good demand for coke and prices on the spot market remain firm.

Coke—Prices asked for coke are: Connellsville, $4.50@4.65; Wise County, $4.50@4.65; byproduct, egg and stove, $4.95; byproduct, nut, $4.55@4.65; gashouse, $4.85.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Screen lump	$2.10@2.15
Domestic lump	2.50@2.60
Egg	2.30@2.40
Screenings	1.47@1.52
Springfield:	
Steam lump	$1.97@2.02
Domestic lump	2.27@2.47
Mine-run	1.82@1.87
Screenings	1.42@1.52
Clinton:	
Steam lump	$2.00@2.10
Domestic lump	2.17@2.37
Mine-run	1.82@2.02
Screenings	1.42@1.52
Pocahontas and New River:	
Mine-run	$3.15
Lump and egg	4.30

Minneapolis—St. Paul

The mild weather of the past two weeks has begun to tell on the wholesale trade and the demand has been less this week than at any time during the last three or four months. If the weather continues mild for another week it is doubtful if business will be good for the balance of the month, as most dealers in the country have plenty of coal on hand and in transit.

Car supply at the docks is good at present. Prices are stationary on all grades of dock coal except screenings, which still sell in the Twin Cities at less than circular. Most of the Illinois operations are holding out for their price on all-rail coal. Harrisburg and Franklin coals seem to have weakened a little.

The large volume of dock trade fell off when the duty was replaced on American coal, Dec. 5.

A comparatively new market has been made at the head of the lakes for anthracite dust. The zinc mines in southwestern Wisconsin have been buying all they can get, and a special rate has been recently made from the docks to this point. Formerly this was hard to dispose of at 15c. per ton. It is used for smelting zinc ore, and when mixed with the ore it has the effect of cleaning out foreign substances. These zinc companies have taken all the dust Chicago could furnish at a good price, and have made a proposition to Eastern anthracite shippers to take all they can furnish from Erie loading ports.

St. Louis, Mo.

Trade is worse, if anything, and has been since the latter part of last week, when prices on all grades simply went to pieces. Perhaps the market has recovered some from the demoralization it experienced Monday, when Standard went down to 90c. for 2-in. lump and $1 for 6-in.; all other coals followed in proportion.

A careful canvass of the steam plants in St. Louis shows supplies are small, and the retail companies are not stocking any beyond that they have contracted for and must take from the operators. This same situation applies to country trade, which means there will be a hand-to-mouth business until after the first of the year.

The prevailing prices are:

Franklin County:	
6-in. lump	$1.50@1.60
3x6-in. egg	1.50@1.60
No. 1 nut	1.35@1.45
No. 2 nut	1.20@1.25
No. 3 nut	1.10@1.15
2-in. screenings	0.65@0.70
Carterville:	
6-in. lump	$1.35@1.45
3x6-in. egg	1.35@1.45
No. 1 nut	1.20@1.30
No. 2 nut	1.00@1.10
No. 3 nut	0.90@1.00
2-in. screenings	0.60@0.65
Mine-run	1.00@1.05
No. 1 washed	1.50@1.60
No. 2 washed	1.20@1.30
No. 3 washed	1.15@1.25

The higher-grade coals from the inner district, such as the Trenton, and others, are holding good at $2, but the demand is falling off. There is very little coal moving in from the Springfield district and this also applies to the Saline County and Gallatin County fields as well. Big Muddy coal is still firm at $2.25 for 6-in. lump and $2 for 2-in. There has been a falling off in the demand for anthracite, and the size that is in greatest demand now is chestnut, at the current circular. There is a good demand for coke, both gas-house and byproduct at the same prices as have existed for the past three weeks.

Spokane, Wash.

The general conditions are favorable and at present, the supply seems to be almost greater than the demand, one company having said that they have enough coal on hand to supply the entire city for a week or ten days without effort. The mines in British Columbia have recently commenced shipping to this territory. The stocks are becoming rather low but shipments are good and supplies no doubt will be adequate.

A comparative statement of wholesale and retail prices for the months of November and December is as follows, in short tons:

Grade	December		November	
	Wholesale	Retail	Wholesale	Retail
Rock Springs	$7.20	$9.00	$7.20	$9.00
Owl Creek	7.20	9.00	7.20	9.00
Kirby	7.20	9.00	7.20	9.00
Carney	6.70	8.50	6.70	8.50
Bearcreek	6.35	8.25	6.35	8.25
Roslyn steam	5.25	6.25	5.25	6.25
Canadian steam	5.25	6.25	5.25	6.25

San Francisco

Owing to the fall in temperature during the past two weeks, there has been a brisk demand in the retail trade. Cool nights and mornings make the use of coal a necessity.

An arrival of British Columbia, Wellington coal, due here this week, will come to a market bare of that grade, none having arrived since Nov. 2.

The arrivals of Australian coal total 14,293 tons, a quantity equal to all present demands, and the quality making an acceptable temporary substitute for Wellington.

Other arrivals are 5670 tons steam coal from Comox, British Columbia, 6000 tons from Norfolk for the U. S. Navy and 3534 tons domestic from Puget Sound.

The state is now being visited with welcome rains which will give additional impetus to the trade. The wholesale prices, ex-bunker or at ship's side, are as follows per short ton:

Wellington, clean	$8.00
Wellington, average	7.50
Australian, clean	8.00
Australian, average	7.50
Puget Sound, clean	6.50
Puget Sound, steam ....$5.00 and	5.50
Pennsylvania anthracite	15.00
Colorado anthracite	12.50
New Mexico anthracite	13.50
Anthracite briquets	10.00
Cumberland, smithing	12.50
Utah, Wyoming and New Mexico, clean (for domestic use only)....$9.00 and	8.00

Production and Transportation Statistics

Anthracite

Anthracite shipments for the first 11 months of the present year, as compared with the same period last year, were as follows, in long tons:

ANTHRACITE SHIPMENTS

Companies	1910	1911
Philadelphia & Reading	11,181,353	12,027,031
Lehigh Valley	10,144,602	11,493,295
Jersey Central	7,673,016	8,397,839
Delaware, Lack. & West.	8,736,977	9,042,372
Delaware & Hudson	5,974,235	6,613,809
Pennsylvania	5,549,340	5,893,930
Erie	6,884,945	8,078,086
N. Y., Ontario & West.	2,529,740	2,292,510
Total	58,674,208	63,838,872

Lake Shipments from Toledo

Total shipments from the Hocking Valley docks for the season which is now closed amounted to 2,419,640 tons. During the season of 1910 shipments were 2,077,614 tons while for 1909 they were 1,273,921 tons.

Lake Trade

Comparative statement of coal passing through the Sault canals up to Nov. 1 for the years 1910 and 1911 is as follows in short tons:

	1910	1911
Anthracite	1,411,345	1,769,567
Bituminous	10,549,041	11,894,878
Total	11,960,386	13,664,445

Foreign Markets

Great Britain

Nearly all sellers are well booked for December, and the market is firm. Good second admiralties are relatively the strongest feature. Best smalls are in better demand and quotations are stiffening.

Approximate quotations are as follows:

Best Welsh steam coal	$4.20
Seconds	4.02
Thirds	3.72
Best dry coals	3.96
Best Monmouthshire	3.69
Seconds	3.48
Best Cardiff small steam coal	2.16
Seconds	1.92

The above prices for Cardiff coals are all f.o.b., Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b., Newport, both exclusive of wharfage and for cash in 30 days, less 2½ per cent. discount.

France

Comparative statement of production, first 6 months of this year as compared with the same period last year is as follows, in metric tons:

	1910	1911
Coal	18,611,086	19,153,543
Lignite	343,247	363,256
Total	18,954,333	19,516,799

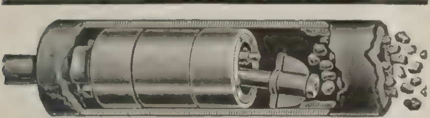
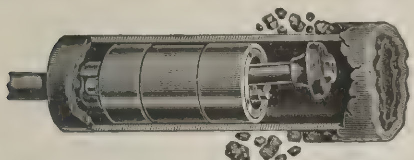
THE Canedy-Otto Mfg. Co., of Chicago Heights, Ill., tried the **Dean Boiler Tube Cleaner** and removed 739 lbs. of scale from one boiler. They kept the cleaner, because "*From the first it plainly demonstrated that the boiler compounds do not keep the scale from forming upon the tubes, nor do they remove scale when same has formed.*"



The Dean removing scale from the tube of a water tube boiler.



The Dean removing scale from the tube of a return tubular boiler.

Would You Not Appreciate The Same Results In Your Mine, Mr. Superintendent?

In the coal mine as in any other industrial establishment, scale on the boiler tubes means lessened efficiency, greater expense, and eventually more shut-downs.

Are you fighting scale formation in your mine boiler plant? And if you are, are you sure that the method you use is keeping the boilers free from *all* scale?

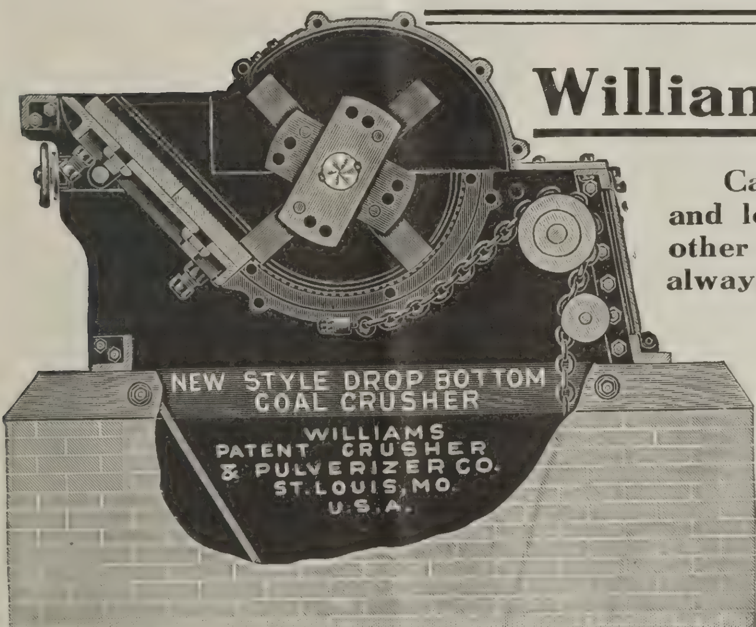
You can make sure without expense to yourself The Dean will be sent on trial and will probably open your eyes to conditions which you had not even suspected. *Why not try it?*

Trial Offer and Guarantee

We send the Dean Boiler Tube Cleaner for free trial on one boiler. The Mine Superintendent can see how it operates and prove to his own satisfaction that it removes all scale. We sell the Dean under a guarantee that it will pay for itself within six months or we will refund money. *Why not send today and see if* **your** *boilers are clean or pretty clean?*

The Wm. B. Pierce Company

335 Washington Street **Buffalo, N. Y.**



Williams Coal Crushers

Can crush more coal with less power and lower cost of maintenance than any other crusher on the market. Product is always uniform.

The remarkable success obtained by Williams Patent Hinged Hammer Coal Crushers is mainly due to the strong construction and the design which makes every part adjustable to itself, adjustable to every other part, and adjustable to wear.

Hammers adjustable to Breaker Plates and Cage. Breaker Plates adjustable to Hammers. Sectional Cages adjustable to Hammers, also adjustable fine or coarse.

By these features grinding diameter is maintained, product is kept uniform, life of grinding parts is prolonged, cost of maintenance is lessened, and horsepower per ton crushed is decreased.

Adjustable Cages, Automatic Dumping Cage and other specially valuable features. ***Write today for Catalog 5 with full particulars.***

Manufactured and licensed under 87 separate and distinct Patents. More than 2000 in daily use.

The Williams Pat. Crusher and Pulverizer Co.

Old Colony Building - Chicago

428 Monadnock Bldg., San Francisco, Cal.
Factory: 2701 No. Broadway, St. Louis.

The New Style Drop Bottom Cage

The breaker plates, hopper bottom, and cage all slide into one large, radial, independent frame (see illustration). This frame is hinged on heavy pivots at the front of machine near the top of hopper. Cage is held in working position by heavy chains at the back of machine which wind around special wheels to which are fastened on the outside of the machine, spur wheels, hand wheels, ratchet wheels, and a pawl for holding cage in working position.

To drop or lower cage when iron gets into machine, the operator simply releases pawl, and the cage drops of its own weight, discharging foreign material as well as partially crushed material into hopper below.

To adjust cage up to hammers when worn, the operator releases the pawl, turns hand wheel slightly, and the chain winds around special wheel and slowly raises cage toward hammers, until it has reached its proper position.

COAL AGE

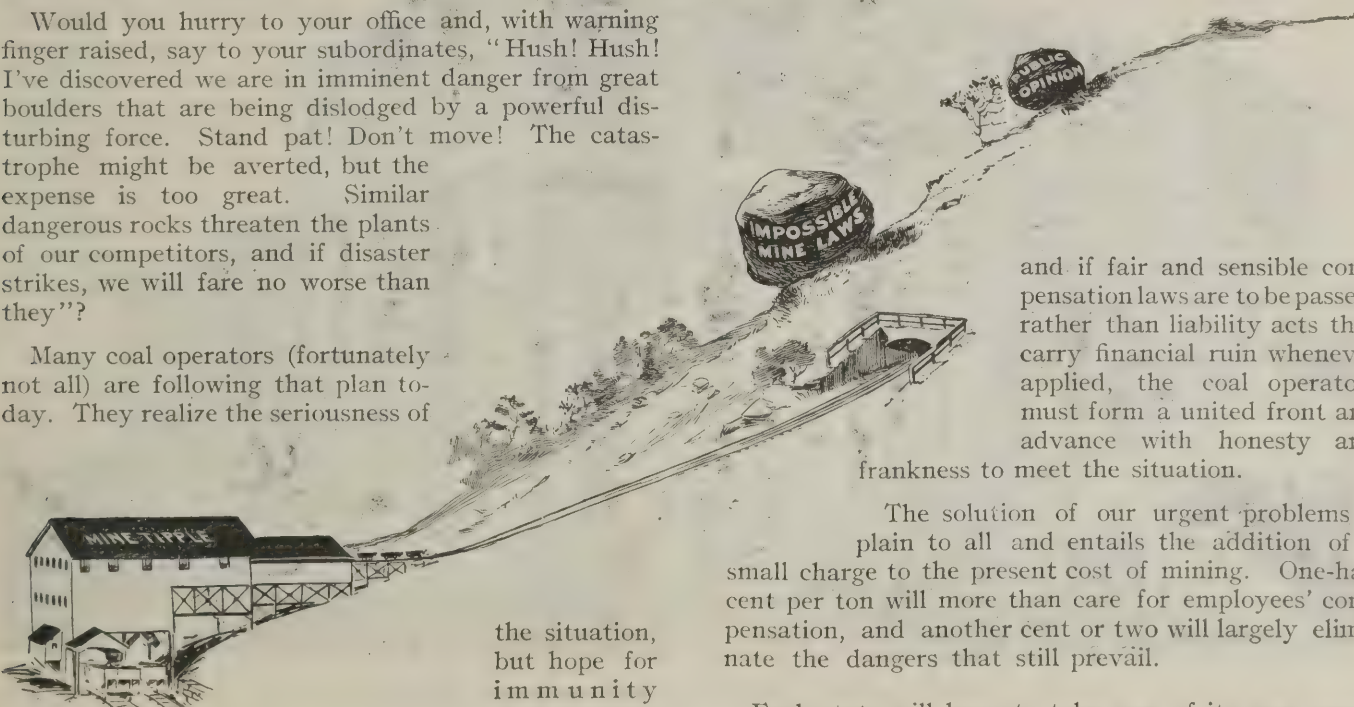
Vol. 1 NEW YORK, DECEMBER 23, 1911 No. 11

Supposing two huge boulders were balanced on the side of a steep hill directly above your mine tipple. Imagine, for illustration, you pass that way and perceive how delicate is the balance of the rocks, and how near they are to crashing down on your mine buildings. Let's assume that on investigation you find a jarring force is acting at frequent intervals to displace these boulders, and that the smaller rock is about to be precipitated against the greater mass below.

Would you hurry to your office and, with warning finger raised, say to your subordinates, "Hush! Hush! I've discovered we are in imminent danger from great boulders that are being dislodged by a powerful disturbing force. Stand pat! Don't move! The catastrophe might be averted, but the expense is too great. Similar dangerous rocks threaten the plants of our competitors, and if disaster strikes, we will fare no worse than they"?

Many coal operators (fortunately not all) are following that plan today. They realize the seriousness of the situation, but hope for immunity they have not striven to secure. The destructive force, *mine explosions*, continues to shake the upper rock, *public opinion*, and before long it will be torn from its base, crash into the greater boulder, *impossible mine laws*, and the combined mass will bury coal operators and their financial investments so deep, even their miners won't be able to dig them out.



We all know there has been an advance in technical knowledge in recent years, but how can we say our mines are safe when actual count today shows that disasters are just as frequent and no less serious. Unless care is exercised, legislation forced by public opinion and enacted by people who are ignorant on the subject of coal mining, will prove a greater burden than the industry can bear.

The operation of a mine includes the assumption of obligations to employees and the public, that are not settled by handing out pay envelopes each fortnight. Efforts are already being made in several states to fix definitely the responsibility of mine owners, and if fair and sensible compensation laws are to be passed, rather than liability acts that carry financial ruin whenever applied, the coal operators must form a united front and advance with honesty and frankness to meet the situation.

The solution of our urgent problems is plain to all and entails the addition of a small charge to the present cost of mining. One-half cent per ton will more than care for employees' compensation, and another cent or two will largely eliminate the dangers that still prevail.

Each state will have to take care of its own operations, and if the larger producers lead the way, the less important coal states will have to follow or show cause in the court of public opinion. The advantage gained by delay will be short-lived and the profits inadequate. In the end, if the industry can't stand the additional costs, the consumer will have to do so, and he'll not complain if the situation is made clear to him.

The coal industry is in the fortunate position of having everything to gain and nothing to lose by laying its cards on the table face up. The man who doesn't try to get from under before the rocks fall, isn't worth digging for after the avalanche.

Taylor Breaker near Scranton, Penn.

By M. A. Walker

The new plant at Taylor is a breaker and washery combined. The building is of reënforced-concrete construction throughout. All machinery will be electrically operated by power supplied at high voltage from a central plant, 3 miles distant.

A reënforced-concrete breaker, equipped throughout with electrically driven machinery, has recently been erected at Taylor, Penn., about three miles southwest of Scranton, by the coal-mining department of the Delaware, Lackawanna & Western R.R. Co. A view of this structure, which is really a breaker and washery combined, is given on the front cover of this issue. The building is quite finished and completely equipped, but connection has not been made with the mines, pending the abandonment and removal of the present plant, and the breaker is therefore not yet in operation.

The new plant will be served by two openings, one a shaft located several hundred feet to the rear of the structure as viewed in the illustration, and the other a slope in the Surface vein. Coal from both openings will be discharged into an inclined conveyor, 250 ft. long, which will run from the surface to the head of the breaker. This conveyor will be of the scraper type with 4-ft. flights and Monobar chain, and will be supported on a steel bridge and trestle rising to a height of about 140 ft. at the head end.

The breaker is a massive structure, extending 107 ft. along the railroad, having a depth of 133 ft. and rising to a height of 149 ft. above the track level. Beneath it run two railroad tracks where cars will be loaded for shipment, and a wagon road for the accommodation of retail trade. The construction, from foundation to roof, is entirely of reënforced concrete; even the two stairways which give access from the ground to the main floor are concrete monoliths.

When viewed at close range the building gives an impression of great mass and strength. Some of the supporting columns at points of heaviest loading are as much as 38 in. square in section. Compared with the usual 12x12-in. yellow-pine posts of the familiar timber structure of this kind, these columns are apt to seem unduly large, but when it is recalled that concrete, while three times as heavy as timber, has only about one-half the allowable working stress of the latter, the necessity for such large sections is more readily understood, especially when considered in conjunction with the unusually great unsupported length of the columns beneath the Taylor breaker.

A view of the building while under construction is given in Fig. 1. At the time this photograph was taken, concrete work had been completed as far as the top of the loading pockets. Since the structure was finished, the exposed surface of the concrete has been painted with a black pitch-like material known as "Concrete Coating." This acts as a preservative and incidentally does thoroughly and at once what, in all probability, the dust from the breaker would eventually accomplish in any case. A noticeable feature of the construction is the provision made for housing the main elevators. These rise from a depth of 15 or 20 ft. below the ground to the top of the breaker through commodious con-

FIG. 1. VIEW DURING CONSTRUCTION, SHOWING FORMS FOR CONCRETE

crete-walled shafts of evident strength and permanence.

The coal beds of the Lackawanna Valley are in general level seams, lying at no great depth below the surface. Such rock as is removed with the coal is usually of a size that admits of its being easily handled, and since, as a rule, little or no difficulty is experienced in unwatering the mines, the coal comes to the surface comparatively clean and dry. The process of preparation does not, therefore, include washing or jigging of the coal except in connection with the smaller sizes and as a last resort in the case of a portion of the larger material which is beyond the scope of mechanical picking.

The scheme of preparation at the Taylor breaker is briefly as follows: Run-of-mine coal from the main conveyors is discharged onto a bank of three head-screen shakers. Lump and steamboat coal pass off the top screen, grate and egg sizes being made on the other two. The lump and steamboat coal from the top shaker is run into two picking chutes along the sides of which stand a number of men who remove the slate from the coal. The grate and egg sizes are each conducted over two spiral pickers and the stove and smaller sizes passing through the last head screen are led to two banks of mud-coal shakers. The bony coal from the grate and egg head-screen spirals is taken to a set of No. 2 pony rolls and crushed. There thus originate at the head of the breaker three distinct streams of coal which may be identified by the name of the screens over which they are subsequently sized: the main-screen coal, the mud-screen coal and the pony-screen coal.

The main-screen coal comes from the lump and steamboat, which is hand-cleaned at the head of the breaker. After passing through the crusher rolls it is led to a bank of two shakers which make grate and egg size. These sizes are each passed over two sets of Emery pickers and sent to the pockets. The undersize from the main-screen shakers passes to two banks of counter-main-screen shakers where stove, nut and pea coal sizes are made. The stove and nut sizes from these latter each pass over two sets of Emery pickers and thence go to the pockets. The pea coal is not subjected to further mechanical picking. Buckwheat and smaller go to the washery.

As previously noted, there are two banks of mud-coal shaking screens. These make stove, nut and pea sizes. The stove and nut are each passed over two sets of Emery pickers and the pea coal is led over four spiral pickers. The buckwheat and smaller sizes go to the washery.

Coal from the No. 2 pony rolls, together with that brought up by the lip-screen elevators, is handled over two banks of pony-coal shaking screens, which separate grate, egg, stove, nut and pea sizes. The egg, stove and nut sizes are each passed over two sets of Emery pickers. The pea coal is passed over four spiral pickers and the buckwheat and smaller sizes go to the washery.

The tailings from all the mechanical pickers are collected and elevated to a set of shaking screens at the top of the breaker which separates them into egg, stove and nut-coal sizes. Each of these several sizes is then passed over two sets of Emery pickers and four spiral pickers. The pea coal and smaller sizes from the tailings screens go to the washery. The rock which is removed from the coal during its passage through the breaker is run to a conveyor, which carries it to a pulverizer, and after being crushed is used for silting in the mines.

The washery handles the fine coal and bony coal from the breaker, as previously noted, and also such coal as may be condemned for excess of impurities. All this material is delivered to the washery screens by the main elevators, which have 20x28x15-in. gravity-discharge buckets. One bank of head-screens takes off grate and egg-coal sizes. Two banks of No. 2 screens make stove, nut and pea-coal sizes, and two banks of No. 3 screens make buckwheat, rice and No. 1 and No. 2 barley. The egg and stove-coal sizes are each jigged once. The nut, pea and buckwheat sizes are jigged and then rejigged. There are three sets of rolls in the washery arranged to feed into the main elevators. These rolls are used for breaking down boney coal, of stove, nut and pea-coal sizes, respectively.

Following is given a tabulated statement of machinery in both breaker and washery:

SHAKING SCREENS IN BREAKER

Head screens	
1 lump and steamboat	5×12 ft.
1 grate	6×12 ft.
1 egg	6×12 ft.
Main screens	
1 grate	5×15 ft.
1 egg	6×15 ft.
Counter main screens	
2 stove	5×21 ft.
2 nut	6×21 ft.
2 pea	6×21 ft.
Mud screens	
2 stove	5×18 ft.
2 nut	6×18 ft.
2 pea	6×18 ft.
Pony screens	
2 egg and grate	5×24 ft.
2 stove	5×21 ft.
2 nut	6×21 ft.
2 pea	6×21 ft.
Tailings screens	
1 egg	5×12 ft.
1 stove	6×12 ft.
1 nut	6×12 ft.

SHAKING SCREENS IN WASHERY

Head screens	
1 grate	5×12 ft.
1 egg	6×12 ft.
No. 2 screens	
2 stove	5×21 ft.
2 nut	6×21 ft
2 pea	6×21 ft
No. 3 screens	
2 buckwheat	5×30 ft.
2 rice	5×30 ft.
2 No. 1 barley	6×30 ft.
2 No. 2 barley	6×30 ft.

ELEVATORS AND CONVEYORS

Main elevators, 20×28×15-in. gravity discharge. Bottom lift, 67 ft. 6 in.; top lift, 58 ft. 6 in.
Lip-screen elevators, 11½×24×18½-in. buckets. Bottom lift, 51 ft.; top lift, 65 ft.
Tailings elevator, 11½×24×18½-in. buckets
Buckwheat elevators, 11×18½×18-in. buckets

Rock conveyor	10×20-in. flights
Bone conveyor	10×20-in. flights
Fine coal conveyor	10×20-in. flights
Tailings conveyor	10×20-in. flights
Cross conveyor	10×20-in, flights
Lip screen conveyor	5×12-in. flights

All machinery in the Taylor breaker will be electrically driven. Three-phase alternating current at 2200 volts will be brought from the Lackawanna company's Hampden plant in Scranton to a transformer house on the ground at the rear of the breaker. Three single-phase Westinghouse transformers are installed at this point and will deliver power at 440 volts for the use of the operating motors. These latter are of the Westinghouse squirrel-cage induction type, and are uniformly of 5, 10, 20, 30 or 50 hp. rated capacity. Friction clutches, inserted in the transmission gearing between the motor and the driven machines, provide both a necessary means for starting up under load and a safeguard against overloading, although the motors have a rated capacity considerably above the probable demand.

Following is a list of the motors in both the breaker and the washery sections:

MOTORS IN BREAKER

2—20 h.p. for lip screen elevator
1—20 h.p. for tailings elevator
1—10 h.p. for tailings conveyor
1—10 h.p. for cross conveyor
2— 5 h.p. for lip-screen conveyor
1—20 h.p. for head screens
1—20 h.p. for main screens
2—20 h.p. for counter main screens
2—20 h.p. for mud screens
2—30 h.p. for pony screens
1—20 h.p. for tailings
1—30 h.p. for main rolls
1—20 h.p. for pony rolls
1—20 h.p. for No. 3 rolls

MOTORS IN WASHERY

2—30 h.p. for main elevators
1—20 h.p. for buckwheat elevator
1—20 h.p. for rock conveyor
1—20 h.p. for head screens
1—30 h.p. for No. 2 screens
2—30 h.p. for No. 3 screens
2—50 h.p. for 16 jigs
3—20 h.p. for 3 sets of rolls

Wiring conduits were embedded in the concrete at the time of building and the power lines for both motor and lighting circuits are thus in general concealed and protected. An excellent feature of the installation is the main switchboard, centrally located on the principal floor of the breaker. The entire plant can be controlled from this point and incidentally terminals are provided for taking power measurements, so that the power requirements of any machine or group of machines may be determined at any time by merely connecting the meters at this switchboard.

The breaker will be heated throughout by exhaust steam, which will be conducted through a number of radiator coils variously located and distributed throughout the structure. By means of an exhaust fan and metal ducts which connect with all the screens, rolls, elevators, etc., dust will be collected and eliminated as far as possible from the breaker. This plant was designed by Mr. Samson, superintendent of construction, and H. M. Warren, electrical engineer, under the supervision of R. A. Phillips, general superintendent of the coal-mining department, Delaware, Lackawanna & Western R.R. Co. The reënforced-concrete work was designed and built by the Hennebique Construction Co., of New York City.

Coal Mining Institute of America

Editorial Correspondence

The winter meeting held in Pittsburg developed the most interesting discussions that have occurred before this body in several years. A. W. Calloway elected president.

The winter session of the Coal Mining Institute of America was called to order at 10 a.m., Tuesday, Dec. 19, in the auditorium of the Engineers' Society of Western Pennsylvania, by G. A. Taylor, the president of the institute.

Mr. Taylor refused to accept the presidency for the coming year because of his many other engagements. The election stood between A. W. Calloway, general superintendent Rochester & Pittsburg Coal Co., W. E. Fohl, consulting engineer, and I. G. Roby, state mine inspector. Mr. Roby declined to accept the position, and the choice of the institute fell on Mr. Calloway. J. K. Johnston, W. E. Fohl and Elias Phillips were elected vice-presidents. C. L. Fay was unanimously reëlected secretary-treasurer. Jas. Scurfield, Nicholas Evans, S. A. Taylor and Austin King were elected additional members of the executive board.

E. W. Parker, coal statistician of the U. S. Geol. Sur., spoke on his work in collecting figures relating to the coal industry. He remarked that it was an open question whether more coal had been produced in 1911 than in 1910.

The afternoon session was devoted to discussion, with Thomas K. Adams, mine inspector, in the chair. The first discussion was on the Employers' Liability Act vs. the Workmen's Compensation Act. Sion B. Smith, who has made a study of the subject in all its aspects, pointed out that the present liability provisions cast an uncertain burden on the operator. He stated that the mine owner did not know what he might be compelled to pay, and so long as such conditions exist, the operation of a small coal mine is in the nature of a gamble. An accident might load the owners of any mine with a crushing burden which might drive them out of business. The large operators could face the possibilities with more equanimity because of the multiplicity of their interests.

Employment of Boys in Mines

In answer to the question, "Is the act of June 15, 1911, regarding the employment of boys, advisable?" it was pointed out that boys could work outside the mines from 14 years of age upward, but in the mine the limit stood at 16 years. This was regarded by Mr. Cunningham as a restriction of the rights of the mining industry, tending to deplete it of its most promising material. The boy would enter some other form of employment at the formative age of 14 years, and later continue at his newly found line of work. It would not keep him any longer at school than till such time as he arrived at 14 years of age. After that, as he could not work in the mine, he would drift into some other industry or into unfortunate pursuits.

Mr. Crane admitted that certain forms of outside work were more desirable than mine work, but advocated the restriction preventing boys from entering the mines till 16 years of age.

It seemed, however, to be the general opinion that the period of exclusion between 14 and 16 years would not promote education, but would deplete the mining industry of native labor, which labor would be performed by foreigners, who need education to fit them for the work.

Falls of Roof

"How can the number of accidents from falls of roof be reduced?" was then discussed. Mr. Roby advocated the employment of rib-bosses, whose authority should be exercised over about 40 men, if all these men were working along one line of fracture. He thought one man could not control as many men if they were scattered at widely separated points, so that the bosses would have far to travel.

He urged that the assistant bosses should report to the mine foreman the names of all miners who are not properly posting the roof. Discipline was emphasized. Mr. Fay suggested that "the man higher up" should insist on discipline, and he felt that then a sense of its importance would filter down. Mr. Affelder said he knew of one operator who enforced the law rigidly relative to the prohibition of all men, but the motorman and brakeman, from riding on the motor. He said the superintendent had been ordered off the motor by the motorman, but that motorman finally failed in obeying instructions and permitted one man to ride—the mine inspector.

Mr. Hall recommended the Summary Jurisdiction Act of Great Britain to the attention of those present, urging that the justice of the peace should be empowered to adjudicate the smaller breaches of discipline. The Court of Quarter Session met too seldom; the cost of conducting a case before it was too costly and took too much of the inspector's time so that he frequently let offenses pass uncorrected to save the time needed for more considerable matters. He also called attention to the difficulty in subpœnaing witnesses, many of them foreigners who would decamp rather than appear in court.

Mr. Taylor said that such a law would fail, owing to the fact that the justice of the peace was elected and therefore subject to the overpowering vote of the miners in small mining towns. It seemed, however, the general consensus of opinion that discipline by suspension and discharge was preferable, and, at least in nonunion mines, was possible.

Jesse K. Johnston said that a prevalent cause for lack of discipline was the practice of the labor unions, these bodies assuming the miner was persecuted, not prosecuted. These unions were ready to pay not only attorney's fees, but the fines imposed on offenders.

[*A further account of the meeting with more discussion will be published next week. Mr. Burrell's interesting paper on "Mine Gases" is printed on p. 348 of this issue of* Coal Age.—Editor.]

Retort Oven Plant at Gary, Ind.

Special Correspondence

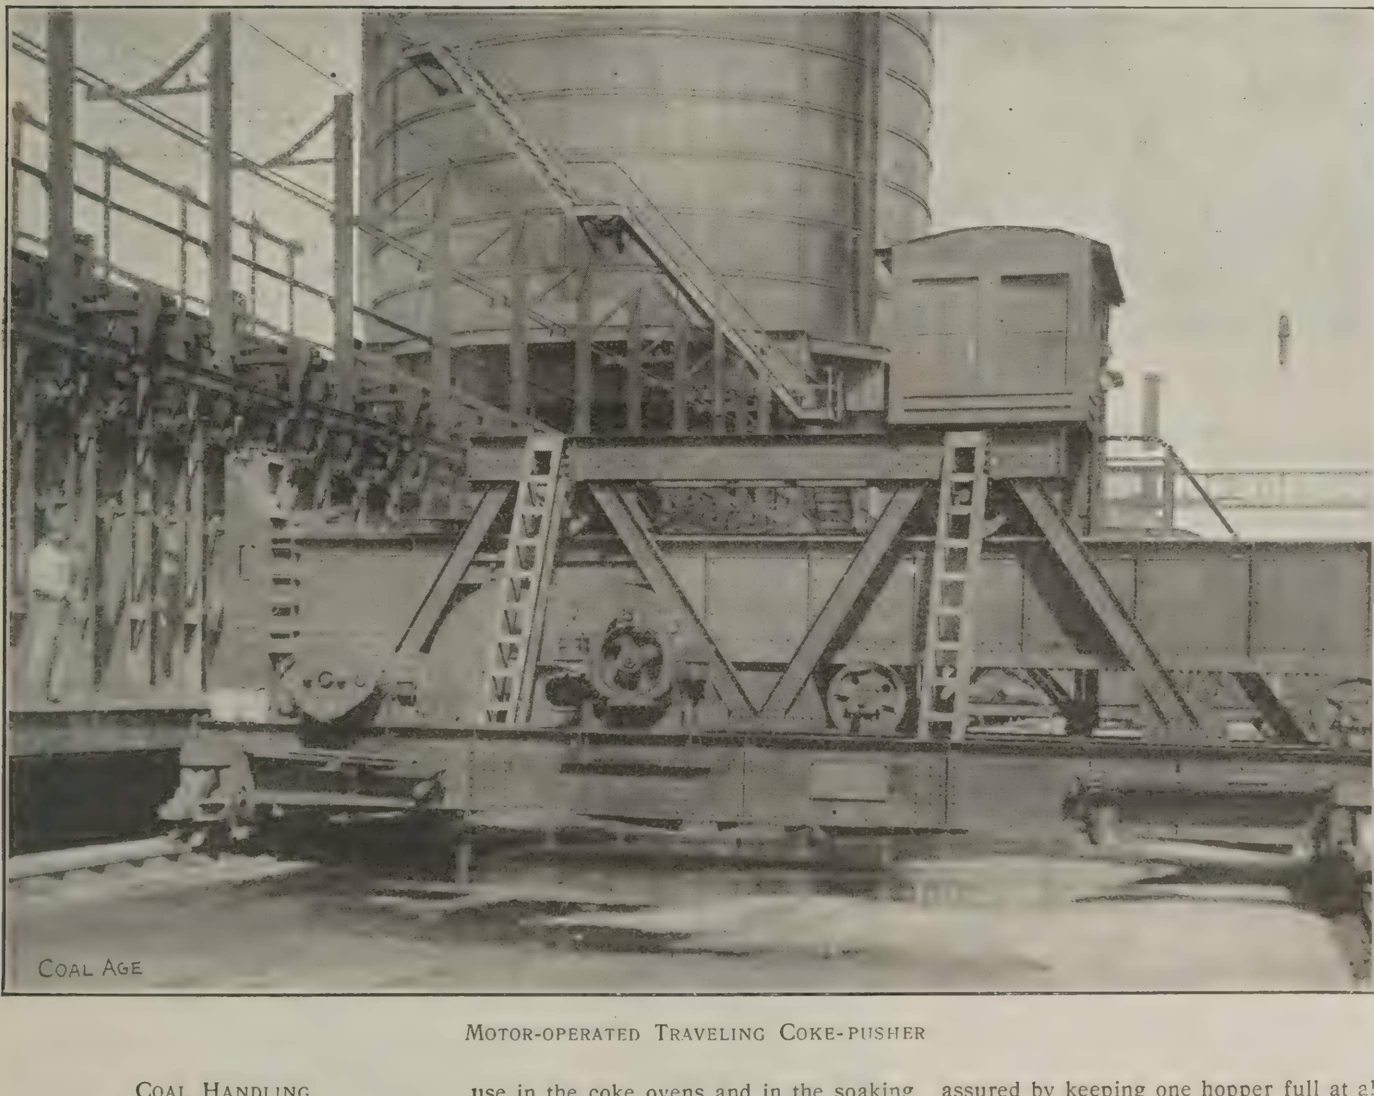
A description of one of the largest and best equipped coal-handling and byproduct plants in the world. Electricity generated with producer gas is used throughout. Capacity of plant when completed will be 9520 tons of coke per 24 hours.

The largest and best equipped coal-handling and byproduct coking plant in the world is at Gary, Ind. It is of special interest because electrically operated by motors receiving their current from the gas-power plant of the largest steel plant on earth.

Another claim to distinction lies in the use of 560 Koppers' Regenerative Byproduct coke ovens, with a total coke capacity of 8000 tons per 24 hours, and Koppers' Modern Direct Process for recovering ammonia from the gas in the form of ammonium sulphate. This is the first coke-oven plant in this country installed with the Direct Process for ammonia recovery.

The bridges are each equipped with 7-ton buckets and can load twenty 50-ton larry cars per hour. Their closing and opening lines and trolley travel are each operated by a 150-hp. General Electric, type MI motor and the two bridge trucks are operated by eight 30-hp. motors of the same type.

Coal, after being loaded into a transfer car, is dumped into one of 12 hoppers at the unloading house. These hoppers are each equipped with a shaker distributor driven by a 15-hp., General Electric, three-phase, squirrel-cage, induction motor. Each of the shakers can evenly distribute 40 tons of coal per hour on the belt conveyors. A continuous supply of coal is assured by keeping one hopper full at all times.



MOTOR-OPERATED TRAVELING COKE-PUSHER

COAL HANDLING

Let us follow the coal from its arrival at the immense storage yard, thence to the breaking and crushing building, on to the mixer building and finally to the coke ovens. We will then follow the coke from the ovens until it is quenched and ready for the blast furnaces; also trace the course of the coke-oven gases through the byproduct house until, freed of tar and ammonia, they are ready for use in the coke ovens and in the soaking pits of the steel plant near-by.

Coal for coke making is dumped from railroad cars into a concrete storage yard which has a capacity of 350,000 tons. The walls of this yard are inclined under the railroad tracks to deflect the coal away from the sides of the yard so the grab buckets of two large Wellman-Seaver-Morgan coal bridges can easily reach it.

The coal is carried from the unloading house by four belt conveyors, each of which has a capacity of 500 tons per hour. They are driven by four 30-hp., three-phase, Form K, General Electric, induction motors which, together with those used to operate the Bradford breakers, hammer-mill crushers and intermediate conveyors, are controlled by a special

electrical interlocking system. The stopping of any conveyor or machine automatically holds up all operations prior to its own, thereby preventing waste or jamming.

Preparing the Coal

The unloading-house conveyors carry the coal to Bradford breakers, each of which has a capacity of 500 tons per hour. It is here broken to 1-in. mesh and separated from what little slate, stone, wood, iron, etc., it may contain. Power for this operation is furnished by four 75-hp., three-phase, General Electric motors.

tors used here are in a separate room built on the side of the house. In many other cases, however, conveyor motors, located near conveyors in other buildings, are showered with coal dust.

Crushed coal is carried from the crusher house to the mixer building by two conveyors, each of which has a capacity of 500 tons per hour. They are 120 ft. long, travel 580 ft. per minute and are housed over to insure protection against the elements. In the mixer house are two 500-ton mixers run by two 15-hp., Form K, General Electric, induction motors with automatic control.

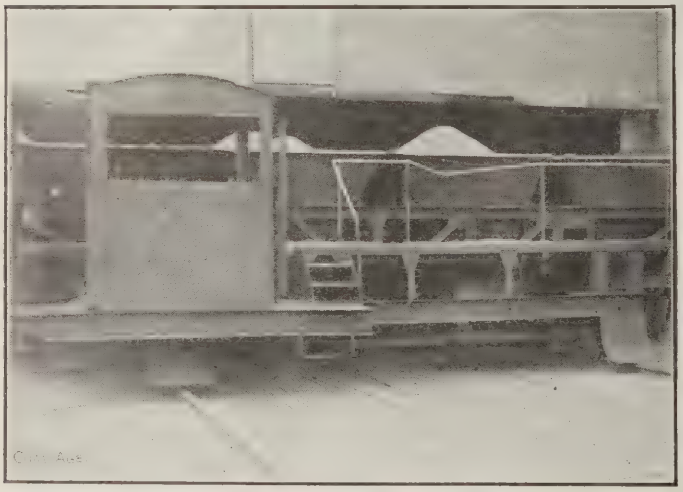
coke-oven batteries. These bins have a capacity of 2100 tons each and the six conveyors will completely fill them every 10 hours. The conveyors are driven by two 100-hp., two 75-hp. and two 30-hp., three-phase, Form K, General Electric, induction motors. It is unnecessary to run the coal-handling plant at night due to its capacity and that of the storage bins.

Coke Making

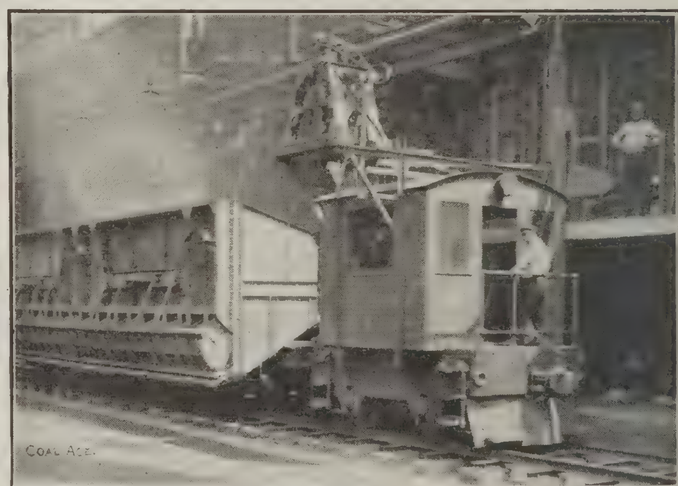
Larry cars run under the storage bins and over the tops of the coke ovens, into each of which they charge 12¾ tons of

Conveyors between Breakers and Hammer Mills

Two Squirrel-cage Motors Driving Hammer Mills



Coal-charging Larry Car



Coke Cars and Locomotive

Between the breakers and the next operation, crushing the coal in hammer-mill crushers so that 85 per cent. of it will pass through a No. 64 wire-mesh screen, are four conveyors. Each of these has a capacity of 500 tons per hour and they are driven by four 30-hp., three-phase, General Electric, induction motors. The eight hammer-mill crushers, with a capacity of 350 tons per hour, are driven by 250-hp., three-phase, Form K, General Electric, induction motors.

As the coal-crushing house is thick with coal dust floating in the air, all mo-

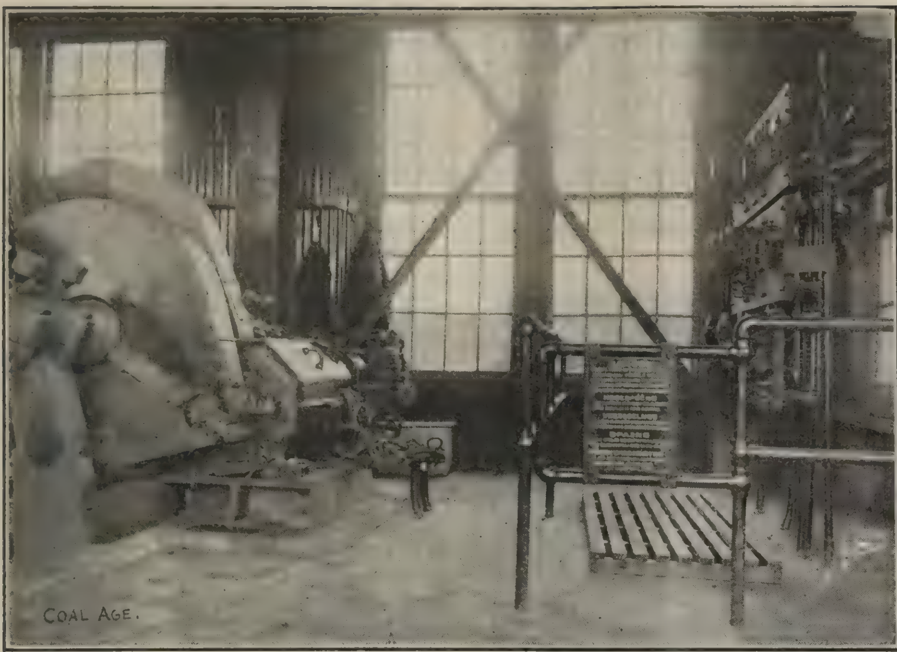
The unloading, breaking and crushing machinery and the mixer are connected by an electric signal system which indicates by electrically operated air whistles, any change in character or mixture of coal being sent through.

The mixer building has a storage capacity of 2000 tons of puverized coal. In it, 80 per cent. Pocahontas and 20 per cent. Ronco coal are mixed, which gives a coke yield of 84 per cent. of the coal charged. From the mixer house six 500-ton conveyors carry the crushed coal to four cylindrical storage bins over the

coal. The coal is then leveled by a traveling leveler which is operated by four 30-hp., General Electric motors. Charging is carried on in a certain prescribed sequence and there are always ovens ready for pushing, thus assuring continuous operation of men and equipment.

Coking requires 18 hours, at which rate the present capacity of the plant is 8000 tons per day; when entirely completed the total capacity will be 9520 tons.

The advantages of the type of oven selected for the Gary plant are interesting.



Motors and Automatic-control Equipment Operating Quenched-coke Hoists

Traveling Door-extractor Driven by a 7-hp. Motor and Located on Discharge Side of Coke Ovens

The ovens are heated with gas evolved from the coal carbonized. The coal yields from 50 to 60 per cent. more gas than necessary for its carbonization, and in the old beehive process this surplus gas is wasted.

A further advantage is that it is not essential that the gas be consumed on the spot directly it is produced, since it can be conveyed any distance without material loss. It can also be stored during the time it is not required and consumed during the working hours of the day.

The regenerators also serve as a storage for heat so that a whole battery of ovens can be shut down entirely for a week or so and started again without any heating up being necessary. This is not possible where regenerators are not used. The regenerators enable the ovens to be worked at less than one-quarter capacity without going cold, whereas most other systems cannot be worked much below their normal capacity without cooling down.

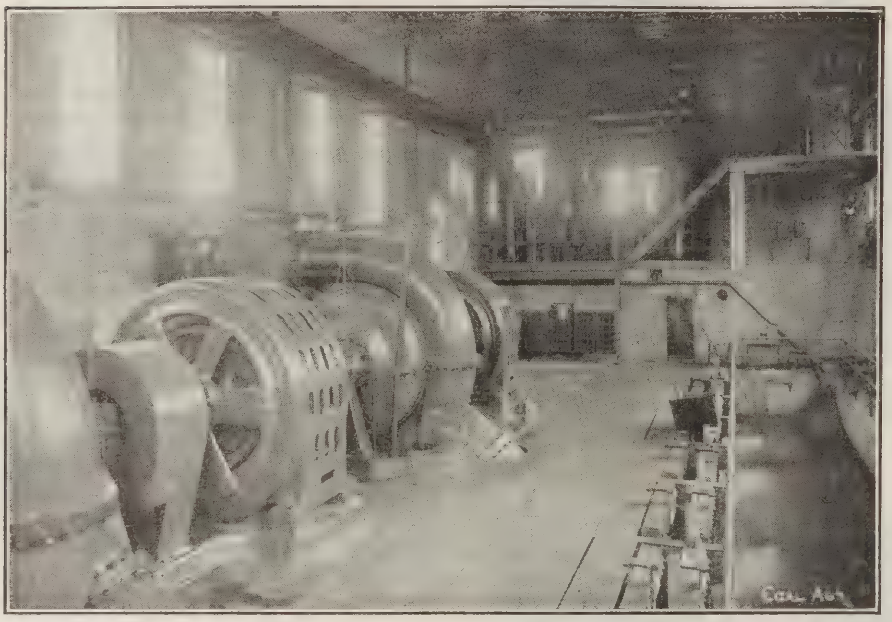
Description of Ovens

The oven chambers are approximately 39 ft. long, 9 ft. 10⅜ in. high and from 17 to 21 in. wide. They have doors at either end, operated by a traveling door machine on the coke-discharge side, and a door machine attached to the coke pusher, at the other side. The top of the oven is provided with openings for charging the coal and an opening through which the gases of distillation are drawn off to the condensing plant.

Referring to the accompanying longitudinal section, the air for combustion flows along the passageways *A*, at the front and back of the ovens, and thence it passes into the regenerators through the inlets *B*. In the regenerators, the temperature of the air rises to 1200° C. (2190° F.). The highly heated air then passes out of the regenerators into the vertical heating flues through the openings *C*. The gas from the byproduct plant, freed from tar and ammonia, is returned to the ovens by the mains *D*, running along the whole length of the ovens on each side. Branch supply pipes *H* conduct the gas into the gas-distributing channels *E*, which are situated directly beneath the oven walls; thence it passes through the gas nozzles *F*, into each vertical flue, where it ignites with the hot air entering through the passage *C*, previously referred to. A jet is, therefore, formed on a level with the oven floor in each of the heating flues in the oven walls.

The employment of regenerators renders it necessary to reverse the heating process after a certain period of time, usually about 30 min. This is done automatically by a General Electric motor-operated dial switch system, which controls the gas and air valves. The system of heating flues is divided into two sections, so that combustion can take place

alternately in each half of the oven wall. When the gas is burning in the flues in one half of the length of the wall, the products of combustion pass up the flues and enter the top horizontal flue *G*, whence they make their way down the flues in the other half of the oven wall; they then enter the regenerator through the same passages *C*, by which the air is



Interior of Pump House

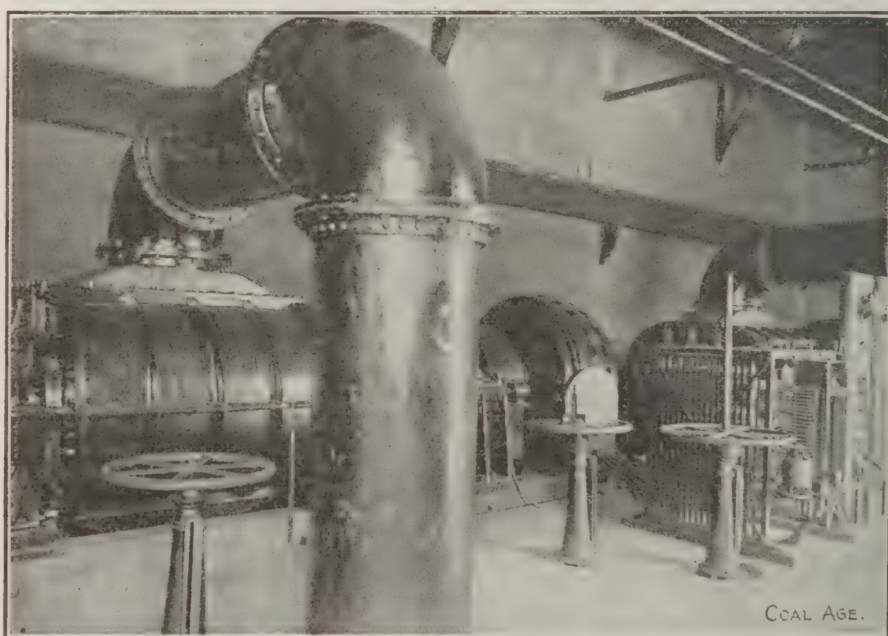
admitted to the flues when the direction of combustion is reversed. On issuing from the regenerator, the waste gases pass into the flue leading to the chimney *I*, after having given up their heat to the checkerwork of firebrick.

Accessibility of Ovens

The products of combustion of the gas and air pass up the heating flues *J*, and through the openings *K*, at the top of each flue. These openings are furnished with dampers *L*, which, together with dampers in the regenerating passages, are easily regulated so as to enable the exact amount of air to enter the flue necessary to effect perfect combustion. The sliding bricks are accessible from the top of the ovens through the openings *M* and *N*, which are fitted with easily removable plugs.

At this point, particular attention is invited to the sliding bricks and to the openings at the top of the ovens, which give ready access to the interiors. These are two of the principal features of these ovens, and distinguish them from all other constructions. The openings at the top of the ovens serve not only to provide means for regulating the dampers, but more particularly to give access to the gas nozzles *F*, and they further permit of the flues being inspected at any time.

Without the facility thus provided for examining the flues, it is not possible to work retort ovens satisfactorily. The gas nozzles are furnished with oval orifices, to enable them to be taken out with a rod having a tee-end. The orifices in the nozzles vary in size, according to their position in the flues. The removal and replacing of a nozzle can be easily effected in a few minutes.



Gas Exhausters Operated by 250-hp. Motors

It happens from time to time in all ovens that dark places appear in the oven walls, indicating that the combustion is defective; in the absence of means of access to the flues, it would be necessary to cool down the oven and break into the walls in order to remedy the defect. By means of the openings over each flue in the Koppers' ovens, the cause of any irregularity in the heating can be immediately detected and, in the great majority of cases, easily rectified in a few moments. The effect of any adjustment in the regulation of the gas and air can, moreover, be immediately seen.

Method of Operating

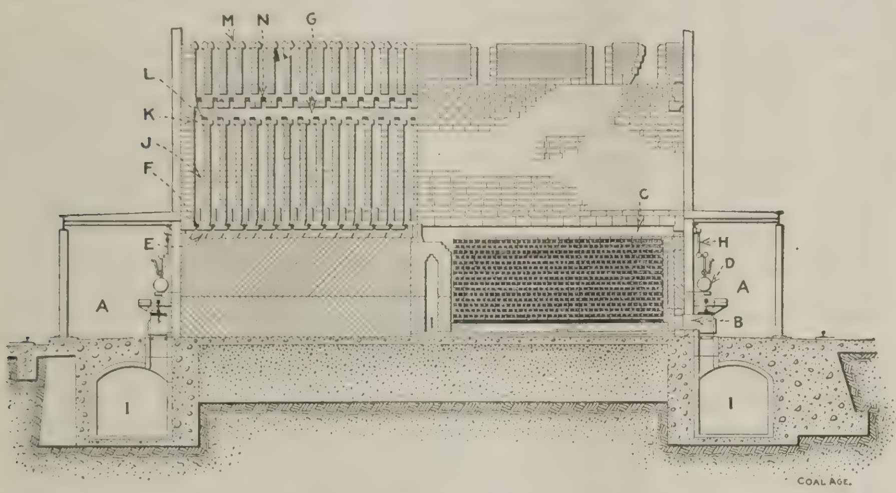
It will have been seen that each oven wall is formed of about 30 vertical flues; each of these flues is provided with a heating jet, and also with means for regulating the admission of the gas and air, viz., by substituting the gas nozzles, and by adjusting the sliding bricks over each flue, respectively. It is, therefore, obvious, that it is a simple matter to control the heating so that the oven walls will be subjected to exactly the same temperature from end to end. This uniformity in the heating, characteristic of the Koppers' ovens, has been sought by coke-oven builders for many years, and unless it be attained, it is impossible to produce a coke which will be homogeneous in character throughout the charge.

When coking is complete, and the gas fully given off, the doors are removed and the charge is pushed out by the traveling ram, which is operated by two 50-hp. and one 7-hp. (the latter on the door opener) General Electric motors.

While being pushed, the coke is partly quenched by water sprinklers, as it falls into a steel and cast-iron car, to which is attached a three-phase, General Electric locomotive, equipped with two 50-hp. type MI motors. As soon as a charge is entirely in the car, it is rushed to the shower hood, where quenching is completed. The coke is then elevated to storage bins by two automatically controlled, 30-hp. General Electric, three-

phase, form K motors, operating elevators. In the final process, the coke is run through screens operated by two 30-hp. motors of the same type.

Each two batteries of ovens are equipped with grinding pans and clay elevators for preparing luting material for the oven doors. These are operated by 15-hp., three-phase, form K, induction motors.



LONGITUDINAL SECTION THROUGH A SINGLE OVEN

Byproducts

The gases from the ovens go through divided water-sealed mains, thence to coolers of the multitubular water-tube type. After passing around the tubes, they leave at a temperature of about 30° C. The gas is then drawn by exhausters, which are driven by 250-hp., General Electric, induction motors, controlled to give a constant gas suction, and delivered to the tar extractors. The tar and ammoniacal liquor, which condense here, are run off along with the condensation from the coolers, and separated by gravity in the tar-separating tank.

From the tar extractors, the gas passes to reheaters, where its temperature is raised to about 70°C. by the use of steam. The heated gas is then conducted to the acid saturators (lead-lined vessels, containing a solution of about 5 per cent. of free sulphuric acid), and the gas leaves the saturators at about 30° C. At this low temperature the chemical affinity between the acid and ammonia is so great that a neutral salt (ammonium sulphate) is easily obtained. The salt is continuously removed from this inclosed type of saturator by an ejector and delivered onto a draining table. From here it is run off, together with the mother liquor, into a centrifugal drier in the usual way. When desired, concentrated ammonia liquor is produced instead of ammonium sulphate.

About 50 per cent. of the total daily yield of about 100,000,000 cu.ft. of gas is used at the steel plant, and the remainder is used to heat the coke ovens. The ammoniacal liquor is treated with lime, to decompose fixed ammonia compounds, and then heated to vaporize the ammonia, which is conducted to the gas main and absorbed in the saturators. About 1 per cent. ammonium sulphate and 2 per cent. of tar is obtained. The coke yield is approximately 84 per cent. of the weight of the coal coked.

This greatest of all coke plants is supplied with 60,000,000 gal. of water a day by two centrifugal pumps, operated by 1300 hp., three-phase, form M, General Electric motors.

Stearns Mines in Kentucky

By J. E. Butler*

The Stearns mines have an uptodate electric equipment and an aerial tramway.

Stearns is on the Cincinnati Southern R.R., 110 miles south of Lexington and 144 miles north of Chattanooga. Here are located the offices of the Stearns Coal & Lumber Co., the Stearns Coal Co., Ltd., the Kentucky & Tennessee Ry. and other companies whose stocks are owned by the Stearns people.

The property consists of approximately 85,000 acres of coal and timber land lying adjacent to the South Fork of the Cumberland River in Whitley, Wayne and Pulaski Counties, Ky., and in Scott, Pickett and Fentress Counties, Tenn.

The coal seams, three in number, are the lowest in the series and are designated locally as Nos. 1, 2 and 3. Only the lower two are being developed. Each is between 4 and 5 ft. in thickness. The coal became commercially accessible by the construction of the Kentucky & Tennessee Ry., which extends from Stearns westward through the property. The coal lies at tipple height above the railroad track. This is not due to chance, but in planning the railroad it was arranged that the elevation of the main line should be approximately 30 ft. below that of the beds where it was convenient to open mines. As it drops down the valley of the South Fork River the railroad intersects the beds successively.

Alternating Current and Sawdust Fuel

The first mine was opened in 1902; since then five more have been put in operation with a present production of 2000 tons daily.

For the purpose of furnishing current to the mines, a central power station was erected at the sawmill located at Stearns. This enabled the mining company to use sawdust as fuel. The plant consists of two Wickes vertical water-tube boilers of 400 hp., twin Buckeye engines, each of 400 hp., directly connected to a 450-kw. 40-cycle three-phase General Electric alternating-current generator.

The current is stepped up to 13,000 volts for the high-tension transmission line which delivers current to the substations at the mines, where it is again transformed to 575 volts. This is used for driving the fans, pumps, air compressor and direct-current generators. These generators furnish current for motor haulage and the chain coal cutters.

Incidentally, it may be mentioned in this connection that this plant has proved inadequate to supply the rapidly growing business and the company is even now planning to erect a new and larger plant at Yamacraw of a capacity not less than 1000 hp. Several types of installations are being figured on, among them a high-pressure steam turbine or a gas engine, using either producer or byproduct gas. As a counter proposition, a low-pressure turbine is being considered to use the exhaust steam from the present plant at Stearns. It has been determined that 500 hp. may be secured in this way.

Motor Haulage

Among the developments of the past year, the installation of motor haulage on the main entries of mine No. 4 must be considered. The coal is gathered from the room partings by mules and delivered

*General manager, Stearns Coal & Lumber Co., Stearns, Ky.

Note—Paper read before Kentucky Mining Institute, Lexington, Ky., Dec. 11, 1911.

to sidings on the main entries, where it is picked up in trips of good length and taken to the tipple. Previous to introducing the motors every effort, consistent with economy, was made to reduce gradients to a minimum and to ease curves and straighten roads. The track was then relaid with 25- or 35-lb. steel on white-oak ties, 5x6x5½ in., spaced with 18-in. centers. The compressed terminal bond, consisting of a head on the end of a copper conductor, is used. The head is compressed into a drillhole in the rail by means of a screwjack, which exerts a pressure of from 10 to 20 tons on the head of the bond, causing the copper to expand in the hole and form an intimate contact. These bonds have thus far eliminated the troubles arising from poor contacts. The trolley wire is 0000 V-grooved; the machine wire is No. 4; the clamps are of the "sure-grip" type. On the outside hauls the trolley is strung on 8-in. round chestnut poles set 30 ft. apart with 3x5-in. white-oak crossarms. Power is obtained from a Jeffrey 150-kw. motor-generator set. Three haulage motors are used, one 8-ton and two 5-ton, all Jeffrey equipment. The plant, while small and compact, is installed in a substantial manner and has to date reached all expectations.

Aerial Tramway

Within the current year a new mine, designated as No. 11, was opened at Yamacraw on the west bank of the South Fork River. As the railroad is on the east bank, it became necessary to provide means for getting the coal across the river temporarily for the development work and later for permanent operation.

For the preliminary work, an old steam log-loading machine was set up near the railroad. A 1¼-in. plow-steel cable was strung over the river and on this was suspended, from a trolley, a bucket of two tons capacity. The coal was dumped from the mine car, through a short chute, directly into the bucket, pulled across the river, dropped into railway cars and shipped as run-of-mine. With this equipment a capacity of 150 tons in 9 hours was obtained at a cost not to exceed 10c. per ton and the wasteful practice of stocking the development coal in the mineyard avoided.

When the permanent equipment was ready for use on Nov. 1 this year, over 2000 ft. of entry and aircourse and 40 rooms were ready for the miners.

The permanent equipment consists of a Broderick & Bascom reciprocating aërial tramway of 550 ft. clear span, operated by a 35-hp. General Electric, variable-speed motor, geared to the main-driving wheel of the tramway. The 1¾-in. lock-coil track cables reach from cliff to cliff across the river and are anchored in solid rock and concrete. The traction cables are ⅝-in. plow steel. The buckets are of 52-cu.ft. capacity and travel at a speed of 800 ft. per minute.

Tipple Facilities

On coming from the mines the coal is dumped from the mine cars over a Phillips automatic kick-back tip onto the ridge of a 60-ton bin built in the shape of the letter "W." The buckets are alternately loaded through undercut gates at the bottom of the bin. At the tipple the bucket doors are automatically tripped and the coal discharges onto shaker screens of the suspended type, designed to separate four sizes of coal at any given time, but several combinations of sizes may be obtained by the opening and closing of valves in the main pan. This may be done without stopping the screen. The shaker shaft is driven at 120 r.p.m. by means of a 12-hp. induction-motor belt.

The present capacity of the tramway, which is operated by one man, is 500 tons in 9 hours and it consumes 20 to 28 hp. By increasing the size of the buckets and their speed, they may be made to handle 1000 tons daily.

The arrangement of the mineyard may be of interest. The horns of the tipple are exactly 100 ft. from the mine mouth. On this account it was necessary to extend sidings into the mines. Gradients are so arranged as to provide 200 ft. of 1½ per cent. in favor of the loads and a corresponding 200 ft. of 1½ per cent. in favor of the empties, which return to the mine through a second entry. With such favorable grades, with cars having roller-bearing wheels and with the aid of the automatic tip, one man has weighed and tipped alone 331 tons of coal in 9 hours.

Concrete Form for New Tipple at Stearns Mine No. 10

New Concrete Tipple

In order to double tonnage and shorten the hauls at mine No. 10, new openings are being made and a concrete tipple equipped with shaker screens is in course of construction. A railroad yard of like capacity is being graded.

The forms of the new tipple are being built and the reënforcing steel placed. The concrete will be poured continuously, making a monolithic structure. The screens are constructed under the supervision of the Associated Engineering Co., of Louisville.

The tipple will be equipped with double automatic kick-back dumps and the empty cars will return to the mines on either side of the main entry over a 1½ per cent. downgrade. Likewise, the loads will run by gravity from any point 1500 ft. back from the mouth of the mine over a 1½ per cent. grade. The tipple horns are but 75 ft. from the mine mouth and loads and empties at the tipple will stand under cover. At this mine an 8-ft. Jeffrey disk fan, designed for low pressures, has been installed. It is driven by a 12-hp. induction motor. It delivers 35,000 cu.ft. of air per min. at a 0.2-in. water gage. The other mines are similarly ventilated.

Within the near future, work will be started on a central tipple of 1500 tons capacity at mine No. 4. The tonnage of that mine will be increased by that from several openings on the opposite side of the river and the coal will be transferred over an aërial tramway similar to that at mine No. 11, but this bucket train will be designed for a greater capacity, or else a wire bridge will be erected to span the valley, by which cars will be brought across the river. As it will be necessary to provide means for employees to cross to their work, a combination foot bridge and car haul will probably be constructed.

This year's developments have called for the construction of 60 dwellings, which brings the total up to 350. Work of this character will be continued until a tonnage of 5000 tons is ultimately reached, but 3000 tons per day is expected in a short time.

The Briceville Mine Explosion

By R. Dawson Hall

A gas explosion in an open-light mine develops great force from the presence of much dry coal dust. Cars in use have no front gates and spill coal freely on roadways. Moistening of entries by watercar method. Fan set at foot of shaft.

A severe explosion, probably resulting in the death of 84 men, occurred in Cross Mountain mine No. 1 on Dec. 9, at 7:20 a.m. The mine was operated by the Knoxville Iron Co. of Knoxville, Tenn.

Thirty-nine miles north of Knoxville by the Southern R.R. in the County of Anderson, which is in the eastern part of the State of Tennessee, is a small town by the name of Coal Creek, named from a stream of no importance which empties its waters into the Clinch River. At this town the Southern R.R. (Knoxville & Jelico division) puts out a spur to the mines around Fraterville and Briceville, the roadway following the general south-southwesterly direction of Coal Creek.

TIPPLE OF KNOXVILLE IRON CO. MINE, BRICEVILLE, ANDERSON COUNTY, TENN.

Geology of Section

The geology of the Briceville region is interesting. Barely ¼ mile southeastward from that village, the measures have risen in such a steep anticline that, centuries ago, the coal strata were completely eroded, but while the erosion was severe, the anticline is still emphasized topographically by the Walden ridge. The hardness of the Lee Conglomerate, combined with the uplift of the measures, has prevented its erosion to the general level of the Clinch River valley.

A mile from Briceville, also southeast, the violence of the folding proved too much for the measures to withstand and a fault resulted so that the highest formation of the Silurian—the Rockwood—abuts on the second Silurian formation known as the Chickamauga limestone. In another mile another branch of the same fault occurs from the same cause. This time the limestone referred to is found to lie side by side with the Rome standstone, a Cambrian formation normally about ¾ of a mile vertically below it. The two branches of the fault ultimately come together further north. Southeastward there is no coal and Briceville is therefore almost at the very edge of the coal field. The village of Coal Creek is also at its extreme margin.

Northwestward of Briceville the lower coal measures stretch almost uninterruptedly. Only in the bottom of the New River valleys is some of the Briceville shale measure exposed. This shale formation contains the bed mined at Briceville, Coal Creek and Olive Springs.

The Wartburg sandstone lies above this formation. This sandstone, which is, in a less degree, coal-bearing, is, of course, more frequently exposed by the New River tributaries than is the Briceville shale.

Firedamp Present

It might be expected that the measures of the Briceville shale outcropping for miles along Coal Creek and Poplar Creek, would be free of gas. But so large are the undrained reservoirs of gas to the northwest that some gas is found in nearly all the mines near Briceville. Northwestward from that town is the Cross Mountain, 2350 ft. above the water level of Coal Creek, perhaps 2300 ft. above the mine I purpose to describe.

Everyone seems to agree that gas, in quantity enough to start an explosion, has been found in Cross Mountain mine

where the recent explosion took place. As early as Apr. 20, 1897, to give a concrete instance, should such be needed, the inspector in his regular round of duties found "gas at the head of the entries, on the right main entry and the inside heading of the manway." But that this gas was in quantity can be disproved if in no other way than by stating that no damage has occurred from open lights hitherto and that the method of ventilation was by a furnace till the close of 1903. However, gas is said to have been heard issuing from auger holes and the gaseous condition has probably not been improved by the passing of the headings over a trifling "saddle," by the greater distance attained from the cropping of the coal and by the increased depth from the surface.

Mine Classification

It may be here stated that under the Tennessee law the mine was a class "B" mine, which is defined as one "that is dry or dusty to such an extent, as in the best judgment of the chief inspector, renders it subject to dust explosions, and where coal or other dust is deposited on timbers, sides and bottoms of airways, entries or other workings of the mine and where the danger would be increased by too great a velocity of the ventilating currents." On the other hand, class "A" includes all mines known to liberate firedamp, but the judgment of the mine inspector gives him such a degree of latitude that the classification does not necessarily show the absence or presence of gas. The minimum current passing through a mine of class "B" is required to be not less than 100 cu.ft. per min. for each man in the mine.

The Coal Seam

Some 30 beds of coal have been uncovered on Cross Mountain, but only three are over 36 in. thick. The seam worked at the Iron Co.'s mines runs from 3 ft. to 4 ft. 6 in., with an average thickness of 3 ft. 10 in. Irregularity in thickness of deposition seems to be a marked characteristic of the section. The coal is improving in character as the work extends. The earlier work was in dirty coal, the roof being badly seamed and containing fireclay, but at a distance of about 4000 ft. from the drift the coal becomes unaffected by breaks, the roof becoming firm and reliable. The weakness of the roof caused it to fall continuously along the entries. As a result, the main entries in the old portion of the mine are as much as 8 to 14 ft. high.

The coal is a bright, clean coal of excellent quality and of the following analysis:

ANALYSIS OF KNOXVILLE IRON CO.'S COAL

	Per Cent.
Fixed carbon	55.10
Volatile matter	40.75
Ash	3.40
Moisture	0.75
	100.00
Sulphur	0.78

It has definite face- and butt-cleavage. It is not possible to give a well known name to the bed worked at Briceville, but it is termed in Tennessee the Coal Creek bed. This seam is extensively worked. The U. S. Geological Survey, which has surveyed the Briceville quadrangle, has left the correlation of the coal seams as a problem not safely soluble at the present stage of geologic exploration.

Shedded Mining Tracks of Cross Mountain No. 1

Cross Mountain Mine No. 1

The mine is opened in a simple manner. One long, straight, face entry and a parallel airway penetrate Cross Mountain several miles, and from this entry are driven, to right and left, several butt-entries. There are 28 butt-headings to the right, the last being only just started from the main heading. On the left are 26 butt-entries. As the mine dates from the year 1888, it will be readily understood that much has been mined out.

the 14th Right and 16th Left and all earlier headings being finished. The butt-headings each consist of a haulway and parallel airway.

The mine was ventilated by a 7-ft. fan driven by an electric current of 250 volts. This fan for some reason not easily explained was placed at the foot of a shaft, 100 ft. deep. It was placed on a high ridge crossing the heading so that natural draft lessened the work demanded of the fan. This fan was speeded to about 300 r.p.m. In 1905, it was reported by the inspector as "too small for the area under development, which it has to ventilate; and, but for the splendid brick brattices on either side of the main entry, it would be impossible to furnish the adequate amount of air necessary to maintain safe conditions. However, credit is due the men for the air-current passing through the large mine." These brick brattices were placed all along the main entry, the side entries being bratticed with stone or wood, for the most part. The air went up the main entry to the face and returned by two long splits, each of which traversed, in turn, the long working headings to the right and to the left of the main entry. The coal was hauled partly by mules and partly by motors of the Goodman Manufacturing Co.'s make.

The Explosion

The explosion occurred at 7:20 a.m. As often happens, a delay in receiving railroad cars had held up the morning's work. Three men who had gone into the mine with the motor had just returned and 11 men were preparing to go in when the explosion occurred. It is thought that there were 89 men in the mine at that time. As the mine employs about 130 men rumor has persisted in putting the number at 125 and, at first, the men in Cross Mountain, No. 2 were erroneously included in the probable deathlist. There seems to be no doubt but that the explosion originated on a butt-entry to the left, probably not far from the 23rd entry. At this point, the explosion was severe, blowing the gob out of the mouth of the entry into the main face heading with such violence that the heavy iron rails were bent considerably out of line. But the explosion and resulting expansion of gases filled nearly the whole mine. In headings on both sides of the main entry, men were found burned and bruised, showing that both splits of the air-current were affected. The large timbers securing the roof in the lofty haulageways near the mouth of the mine were, in many cases, blown down and, indeed, the evidences of the force of the blast could be seen even near the driftmouth. The timbers were in many cases scorched as if by lightning.

Rescue Work

The rescue work was delayed by the large amount of smoke escaping from the workings and by the bad condition of the headings, the natural results of so violent an explosion. As the fan in the mine was completely destroyed, a fan, shown in the illustration, was brought from the Black Diamond mine adjacent and was set in the mouth of an old drift. This fan forced air into the mine, and proved a potent factor in the subsequent work of recovery.

The 10-ft. Fan from Black Diamond Mine, Forcing Air into Wrecked Mine

When the rescue car of the Bureau of Mines arrived, the direction of the underground work was committed to the representatives of that bureau, the president of the coal company, T. I. Stevenson, assisting the work by maintaining an efficient organization outside and by forwarding men and supplies to aid in the work of clearing the heading. Much of the rescue work was led by J. A. Holmes, the director of the bureau, and by J. W. Paul, the chief of the rescue department, in person. A great deal of helmet work was made necessary by the difficulties in reëstablishing the air-current.

The Men Who Were Saved

The following statement of William Henderson, one of the five men saved after being in the mine nearly 62 hr., was obtained on a visit to his house. His appointed work was drawing a pillar in Room 45 of the 19th Left. The explosion took place as he was about halfway up his room on his way to work. He felt the concussion and heard a noise, but did not think any considerable explosion had taken place. His boy was at the mouth of Room 47 above him and he shouted to him, asking him what he was doing, thinking that he might have caused what little noise and wind-rush he had heard. Looking around, however, he saw smoke, and with his son he went toward the sidetrack of the 18th Left, the coal from 19th Left being drawn into that sidetrack by a diagonal roadway. They went some distance and dropped down in the smoke. Both of them went to sleep, but for what length of time they do not know. Later they woke up and the father suggested their going on further in the same direction. They later met five men from 18th Left. These had already gone out to 16th Left and had come back to find the Hendersons. So together all the men went to 16th Left, the air getting better as they went.

Improvised Safety Chamber

In that heading they built two brattices of slate about 60 ft. apart. They made these approximately gas-tight by throwing slack into the crevices. They stayed there until 9 o'clock Monday (the 11th). They had their dinner pails, but the food was spilled out or spoiled. There was water in tubs which had been used by the mules for drinking purposes, and this dubious liquid was all they had to drink. They felt they could not live in the atmosphere long, as it was becoming befouled, both by their own lamps and by the leakage from outside. The air became so foul that they could only keep their lights burning by fanning fresh air toward the flame. Two men left them at 2 o'clock, Saturday. They have since been found dead. The other men, as aforesaid, stayed till the morning of Monday, when they returned to the sidetrack of the 18th Left. There was no improvement in the air. So they went to the door of the same heading and were met by the rescue corps. The men who had worked in 18th Left were burned. In that heading Dora Irish left his father, as he was dead and penned in under a roof fall. The rescue of the five men aroused great hopes that more would be found alive. Knocking was alleged to have been heard in the Thistle mine, a Coal Creek Mining Co.'s operation, between Cross Mountain No. 1 and Fraterville. It lies to the right of the devastated mine, and it was thought that as the explosion originated on the left, there might be some hope of saving some men toward the right. Chalk marks were found on the walls, but no men. Finally some were found in the section thus marked, but they were dead.

A Dangerous Mine

The Cross Mountain mine was perhaps as well conducted as any mine in its vicinity. In fact, to some it appeared better than any. There was not an excessive number of men in the splits. The bratticing was efficiently performed in the heading. It would seem, however, that an excessive amount of work stood open, at one time, for such a small production. The ventilation should always be proportionate not alone to the men engaged, but to the extent of the workings.

Still, Cross Mountain No. 1 was a dangerous mine, with just enough gas to make the employees unsuspecting, and more than enough dust to make fearful in result the most trifling explosion. Trite but wholesome is the reiterated statement that the least dangerous mines are often the ones to be most dreaded. A dusty mine does not fill the men in it with sufficient apprehension, and a little gas, which never burns anyone, is looked upon with complaisance. The dusty condition has been viewed with apprehension by the inspectors. On July 10, 1897, sprinkling was ordered. In 1905, R. A. Shiflett, chief mine inspector at that time, ordered (1) that the mine be thoroughly inspected by a competent boss within three hours before each shift and before men enter the mine. (2) Shots in headings shall not exceed three in number past the last crosscut. This includes the turning of breakthroughs. (3) Shots in rooms shall not exceed three in number. (4) Use of slack or auger dust for tamping must be discontinued and clay or sand used instead. Some rules follow as to the handling of powder.

Inadequacy of the Water Car

But the following of these rules alone could not suffice. Nor could immunity be expected from an occasional sprinkling by a water car. The dust should be almost entirely removed, and humidification should be by steam. In a mine full of gob-headings the dust must be resting on the rock ledges along every entry so gobbed. The water from a water car cannot reach such accumulations. Steam alone can overcharge the air with moisture, so that every place that the steam enters is wetted. Water cools the air with which it comes in contact, for the air is a little warmer than the water, and its evaporation effects a further cooling. So that were it possible, which is far from true, for the water to saturate completely the air exposed to the spray, the temperature being lower than that of air yet to be met, precipitation of moisture from the air cannot be expected; the air, in fact, will still be able to drain more water from the mine wherever the absence of the cooling spray permits the temperature of the air to rise. Thus all a water car can do is to wet the main roadway and dampen the air to a degree less than saturation, leaving the air-current free to absorb moisture in its further course along the heading and in the rooms. And it is well known how inefficiently it waters slack, which will not

The Main Entry into Cross Mountain No. 1. Unaffected by Explosion

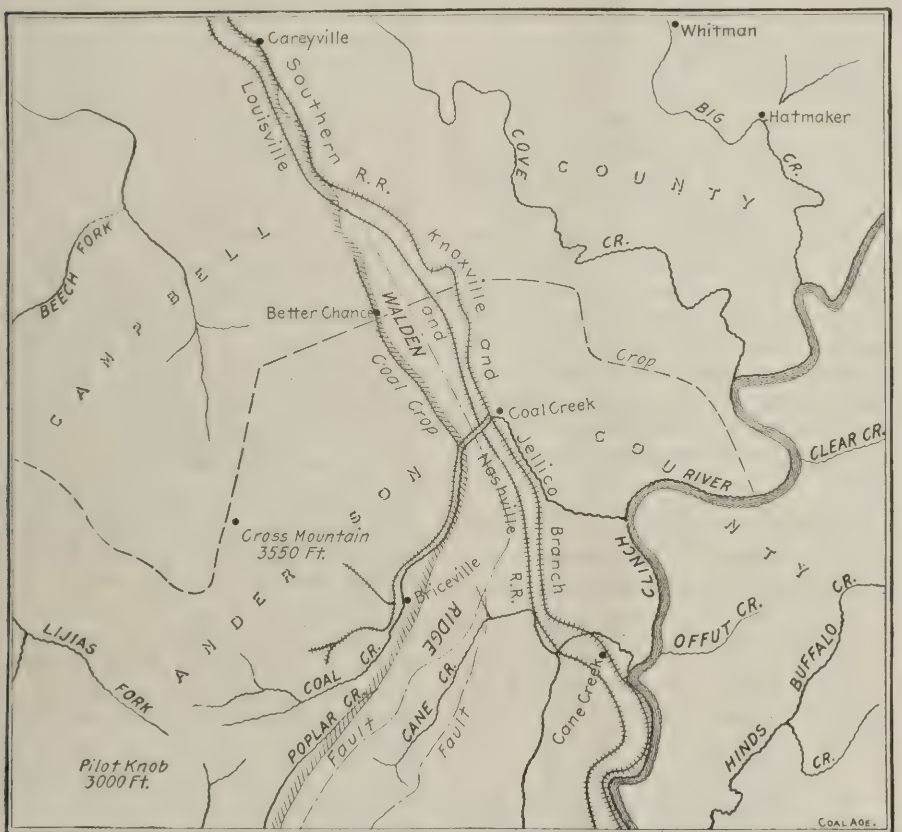
absorb it, and how tardily the water is absorbed by the air.

The Mine Car

The large amount of dust was due in part to the use of a type of car that is not uncommon in the Coal Creek district, but which cannot be too strongly condemned. In these days the tendency is toward a dust-tight car. The car in use was built without a front gate and with an 8-in. rear plank. To replace the front gate is a bar of iron, hinged at one end and latched at the other. On the flaring sideboard is a revolving latch rod, the end of which can be passed through a long slot in the crossbar mentioned. On turning the rod, an offset in the end stands crosswise of the slot and holds the bar in place. As the latch rod is turned to a right angle at its other end, a blow at that extremity revolves the rod, loosens the catch and releases the crossbar. The coal is built up from the very floor of the car, large lumps being placed against the bar and slack shoveled in behind.

The fan, being located in the mine, at the foot of the shaft, instead of on the surface, was destroyed by the force of the explosion. Why such a location should have been chosen is hard to say. Had the fan been intact the rescue work would have proceeded with less delay.

The Cross Mountain mine disaster probably comes with no new lessons, but it is possible that the old advice, which we most need to learn and follow, is the necessity of properly humidifying the mine air, the need of tight cars, the care in the placing of the fan, the danger of a dusty mine and the terrible menace of a little gas. It may be said that at Briceville there is little lack of intelligence among the miners. That is well proved by what has been said about their steadiness in danger, and their consideration for one another when facing death. They are all native Tennesseeans and Kentuckians. Not a colored man nor any convicts were employed in the mine.



Map Showing Briceville and Surrounding Country

Three Types of Coal Pockets

The particular type of construction best adapted for a coal pocket is often difficult to determine and it is therefore interesting to note the opinions in this connection of Archibald G. Monks, of Monks & Johnson, Boston, architects and engineers for coal-handling plants. In his remarks on this subject, Mr. Monks refers to three general types of coal pockets in common use: (1) The all-wood; (2) the combination concrete and wood; (3) the all-concrete.

As to the respective advantages and disadvantages of each type, he remarks that the wooden pocket, while much the cheapest to construct, is subject to the most rapid depreciation, and offers the greatest fire risk, to say nothing of the fact that it requires endless costly repairs. In most cases the dilapidated condition of timber pockets is the result of inadequate supports.

The combination concrete and wood pocket has many of the good qualities of the all-concrete pocket, and can be erected at a much lower cost. Such a pocket has reënforced-concrete columns and floors, with wooden walls, thus using concrete where the greatest strength is desired and where the most rapid depreciation is likely to occur. Mr. Monks states that one of the principal reasons that the cost of construction is lower for the concrete and wood type than for the all-concrete pocket is the fact that in the construction of the former type the wooden forms employed in making the concrete floors and supports are afterward used for building a part of the bin and wall partitions, thus effecting an additional saving beyond the gain from not having to use so many forms. In the all-concrete type the forms are usually thrown away. The second, and perhaps most important item in lowering the cost of these pockets, is the fact that mass concrete per cubic yard is much less expensive than light wall construction. In many cases concrete walls for pockets cost from $1.50 to $2 more per ton of pocket capacity than timber walls.

According to figures compiled by Mr. Monks, the interest alone for 15 years on the extra cost of an all-concrete pocket will more than pay for the entire replacing of the wooden walls of the combination type. In addition, it is difficult to make alterations in the all-concrete pocket, while they may be made with comparative ease in the combination type.

Mr. Monks admits without question that the all-concrete pocket is the best in many respects, but has found that the largest return from the money invested is secured with the pocket of concrete and timber.

Don'ts for Boiler Attendants

Don't overload the safety valves or tamper with them.

Don't let the water level sink out of sight.

Don't allow the cocks and valves to set fast.

Don't open the steam stop valves hurriedly.

Don't empty the boiler while steam is up.

Don't open manholes before easing safety valves.

Don't raise steam hurriedly.

Don't use unknown scale solvent or compositions.

Don't shake ashes against boiler fronts.

Composition of Mine Gases

By G. A. Burrell*

> *Carbon monoxide may be present in exploded firedamp and in waste products of shots. Oxygen is depleted to 3% in stagnant air. As much as 5% of methane may be found in a nongaseous mine. Extinctive atmosphere for lamps defined. Simple apparatus for measuring CH_4.*

The Bureau of Mines has, in the study it has been making of mine gases, examined samples of gases taken under different conditions, analyses of which are here presented.

Incomplete Combustion of Methane

No. 1 Sample: Incomplete combustion of methane. Original mixture contained 10.03% CH_4.

PRODUCTS FOUND AFTER EXPLOSION

10.16% CO_2	0.00% O_2
2.13% CO	0.00% C_2H_4
1.39% H_2	0.00% CH_4
86.32% N_2	

No. 2 Sample: Incomplete combustion of methane. Original mixture contained 10.94% CH_4.

PRODUCTS FOUND AFTER EXPLOSION

8.35% CO_2	0.00% O_2
4.47% CO	0.00% C_2H_4
3.66% H_2	0.00% CH_4
83.52% N_2	

In these experiments pure methane was prepared and mixed with air in such proportion that not enough of the latter was present for the complete combustion of the methane. The mixtures were then exploded and the products of combustion examined. The most explosive proportion of methane and air contains 9.47% of methane. When the latter is increased above this figure, certain products are formed, about which there has been some disagreement. Some investigators have gone on record as saying that no carbon monoxide is formed.

According to these experiments the carbon monoxide and hydrogen increase, and the carbon dioxide decreases as the methane content of the original mixture is raised. Olefine hydrocarbons, acetylene or unburned methane were not found in the products of combustion. The carbon monoxide and carbon dioxide formed, contained all the carbon originally present in the methane. To the carbon monoxide formed in this manner is due some of the carbon monoxide found in the afterdamp following mine explosions. Not all of it, however, and in many cases the smaller proportion, is formed in this manner, because the incandescent carbon of heated coal dust appears to be mainly responsible for the production of the carbon monoxide found after dust explosions by the reduction of CO_2.

Crevice Gases after Shooting

Crevice samples obtained after explosives had been fired in coal mines.

NO. 1 SAMPLE

16.8% CO_2	17.3% CH_4
22.8% CO	8.9% H_2
4.3% O_2	29.9% N_2

NO. 2 SAMPLE

9.1% CO_2	14.1% CH_4
3.2% CO	4.1% H_2
7.5% O_2	62.0% N_2

*Chemist, mine-gas investigation, Bureau of Mines, Pittsburg, Penn.

Note—Paper read before the Coal Mining Institute of America, Pittsburg, Penn., Dec. 20, 1911.

This series of samples shows the gases formed by firing blasting explosives in coal mines. Both black powder and permissible explosives produce noxious gases. These samples were taken from the crevices produced by the breaking down of the coal. The explosive and noxious character of the gases will be observed. The explosive quality accounts for the fact that the miner is sometimes burned when he inocently puts his lamp to the coal to examine the effects of his blast.

Immediate and Later Crevice Gases

No. 1 Sample, crevice sample taken immediately after shot *A* had been fired:

1.40% CO_2	1.40% CH_4
1.45% CO	0.74% H_2
19.31% O_2	75.70% N_2

No. 2 Sample, sample taken 4 min. after shot *A* had been fired:

0.56% CO_2	0.71% CH_4
0.16% CO	0.06% H_2
20.22% O_2	78.29% N_2

No. 3 Sample, crevice sample taken immediately after shot *B* had been fired:

2.50% CO_2	4.88% CH_4
1.21% CO	1.06% H_2
16.91% O_2	73.44% N_2

No. 4 Sample, sample taken 4 min. after shot *B* had been fired:

0.30% CO_2	0.25% CH_4
0.02% CO	0.01% H_2
20.61% O_2	78.81% N_2

This series of samples represents further, gases obtained after explosives had been fired to break down coal. The crevice samples were obtained by proceeding immediately to the face after the shot had been fired and collecting the samples as the gas exuded from the coal crevices. In each case a wait of 4 min. was made, and then the sampler proceeded to the face to collect another sample at about the place the miner would stand to attend to his shot. In one case, 0.16% of carbon monoxide was found, a harmful quantity. The experimental shots were fired under conditions which do not represent the best practice.

Other experiments are being carried on by the bureau to obtain further data on this subject, so as to determine the conditions which lead to the production of harmful quantities of noxious gases. Work thus far accomplished shows that it is bad practice to proceed immediately to the face after a shot has been fired. Even those powders which contain within themselves sufficient oxygen for the complete combustion of the carbonaceous matter present in the explosive, produce, when fired in coal mines, some carbon monoxide, due to a reaction with the carbon of the coal dust. Some explosives, however, are deficient in oxygen.

Deterioration of Motionless Air

COMPOSITION OF GASES FROM AN INCLOSED AREA IN AN ANTHRACITE MINE

Sample No.	Date	Percentages				
		CO_2	CO	O_2	CH_4	N_2
1	Oct. 31....	2.2	0.0	15.0	14.0	68.8
2	Nov. 1....	2.3	0.0	14.6	18.1	65.0
3	Nov. 2....	2.6	0.0	6.2	24.2	67.0
4	Nov. 2....	2.9	0.0	5.7	29.3	62.1
5	Nov. 3....	2.8	0.0	4.1	34.9	58.2
6	Nov. 6....	2.6	0.0	3.0	53.0	41.4

The gases, in this series, show the composition of the atmosphere in an inclosed section of an anthracite mine. This section of the mine was sealed off because of a fire which existed in an adjoining section. The fire did not affect the particular area from which these samples were obtained, because of a heavy intervening roof fall; consequently the gases represent those trapped and given off normally in a stagnant section, except that a stopping was leaking and some air was finding its way into the interior from the ventilating current. The stopping was tightened and the rapid absorption of oxygen by the coal is shown by the third analysis. Four days later the oxygen had dropped to 3%, even though some air was finding access to the inclosed area. The rapid accumulation of methane is also shown, 53% on the sixth day.

Methane in Nongaseous Mine

COMPOSITION OF GASES FROM AN INCLOSED AREA IN A BITUMINOUS MINE

Sample No.	Percentages				
	CO_2	CO	O_2	CH_4	N_2
1	1.50	0.00	0.30	5.29	92.91
2	1.20	0.00	0.30	5.37	93.13

This series of tests shows the composition of gases from an inclosed area in a bituminous mine. A mine fire had once existed in the area and these samples were collected by means of breathing helmets, nine months after the fire had originated and prior to the reopening of the mine. The oxygen had almost entirely disappeared. The mine is classed as nongaseous, yet an accumulation equal to over 5% methane had taken place.

BITUMINOUS MINE-FIRE GASES

Sample No.	Percentages					
	CO_2	CO	O_2	H_2	CH_4	N_2
1	8.07	1.58	1.69	1.37	3.39	83.90
2	9.14	1.32	1.83	1.03	3.60	83.08
3	2.93	0.56	10.34	0.13	0.82	85.22

Samples Nos. 1 and 2 in this series were obtained directly from a fire area, 4 and 7 hours, respectively, after the mine had been sealed off. The fire occurred just inside the pit mouth of a drift bituminous mine. Samples were obtained by boring holes through the thin roof covering. These analyses, with others, showed that air was not leaking in to an appreciable extent, and the existence of an atmosphere that could not further the progress of the fire. No. 3 analysis of this series represents the atmosphere in the same mine about 1400 ft. away from the seat of the fire. An entrance was made through another entry in the mine, with oxygen helmets, and samples of gas were obtained. The party could not proceed farther because of a heavy pall of smoke. It was impossible to better shut off the air, because of various small openings in the outcrop. The oxygen content in sample No. 3 of this series was viewed with some uneasiness, but because of the stagnation of the air and accumulation of blackdamp, it was believed that appreciable diffusion of fresh air into the burning area could not take place. Such proved to be the case.

ANTHRACITE MINE-FIRE GASES

Sample No.	Date	Time	Percentages			
			CO_2	CO	O_2	CH_4
1	Oct. 27	12:00 p.m.	3.5	1.3	8.3	11.5
2	Oct. 27	12:00 p.m.	3.8	0.7	9.6	13 1
3	Oct. 28	9:45 a.m.	3.4	0.6	10.9	10.8
4	Oct. 28	4:00 p.m.	3.4	0.6	11.3	10.3
5	Oct. 28	4:30 p.m.	3.0	0.4	12.6	9.6
6	Oct. 29	11:00 a.m.	3.3	0.6	14.1	9.0
7	Oct. 29	3:30 p.m.	4.0	0.8	13.6	12.0
8	Oct. 30	10:30 a.m.	4.8	1.2	10.1	14.1
9	Oct. 30	5:00 p.m.	4.0	1.0	12.2	12.2
10	Oct. 31	6:30 a.m.	12.2	0.4	6.6	6.6

These tests show the composition of the atmosphere in an inclosed area of an anthracite mine, while a fire existed therein. The bureau men arrived at the scene of the fire on Oct. 27. Dams were in place and water was being forced behind the dams in an effort to flood the fire area. The dams were placed in steeply-pitching chutes, and the water after reaching the roof of the chutes at the dams, had to back up hill in order to reach the seat of the fire. Because of the pitching chutes it was difficult to make the dams hold water. Samples of the atmosphere behind the dams were obtained and analyzed. The first two analyses show the results of the first day's sampling. The two days following, despite efforts to tighten the dams, inleakage of air occurred to such an extent that the fire burst forth with renewed intensity. This happened when the oxygen in Sample No. 6 had risen to 14.1%. The air was inleaking through another dam, and some of the products of combustion were finding exit at the dam where Sample No. 6 was collected. The air fanning the fire into a blaze probably contained about 18% of oxygen.

After Sample No. 6 was taken, the fire was again brought under temporary control, as shown by the decrease in oxygen. The carbon dioxide and carbon monoxide also rose. Then air again started to inleak, and in order to avoid another outburst of fire, a carbon dioxide fire extinguisher was brought into the mine and carbon dioxide was forced behind one of the dams for five hours, checking the fire until new and tighter dams could be built. The rise in carbon dioxide, due to this cause, is shown by Sample No. 10, collected one-half hour after the use of the extinguisher had been discontinued. The new dams held water well and excluded air, so that the fire was rapidly brought under control.

Mine Air in Passage

SAMPLES OF NORMAL MINE AIR FROM DIFFERENT SECTIONS OF A MINE WORKING THE PITTSBURG SEAM

Sample No.	Cu.Ft. of Air per Min.	CO_2, Per Cent.	CH_4, Per Cent.	Cu.Ft. of CH_4 per Min.
1	17,400	0.04	0.10	17
2	21,600	0.06	0.94	203
Return 3	63,000	0.11	0.75	473
Face 4	Air still	0.12	1.80	
Return 5	79,800	0.15	0.19	152
6	21,600	0.06	0.10	22
7	31,500	0.13	0.70	220
Face 8	Air still	0.11	1.38	
9	39,200	0.15	0.75	294
10	8,100	0.09	0.34	28
11	11,400	0.06	0.14	16
12	32,400	0.09	0.94	305
13	23,200	0.05	0.95	220

These tests show the carbon dioxide and methane in the normal mine air of different parts of a large mine working the Pittsburg coal seam. At the time the new Pennsylvania mining code was proposed, embracing certain features relating to the percentage of methane allowable, one of the mining companies asked the bureau to sample the air in its mines with a view to determining just how much methane was present. Since that time the bureau has trained a chemist for the work, installed a gas-analysis apparatus, and the company is now having daily analyses made. It can be stated that the bureau will do this much for other mining companies if they desire closer methane determinations than the safety lamp will show. It might be mentioned that the state inspection department of Alabama, among others, is being given similar aid. The chief mine inspector is installing a laboratory in his office and his men will frequently send in samples.

ATMOSPHERES EXTINCTIVE TO FLAME

Lamp	Percentages	
	CO_2	O_2
Wolf lamp, bonneted	3.00	16.50
Wolf lamp, without bonnet	3.00	15.82
Bunsen burner (natural gas)	3.25	13.90
Acetylene lamp	6.30	11.70
Candle flame	2.95	16.24

In these experiments, the different flames were placed under a 10-liter bell-jar and the atmosphere analyzed after the flames had become extinguished, due to the consumption of oxygen. It might be well to call attention to the tenacity to existence of the acetylene flame. In other words, it will burn in an atmosphere in which the ordinary flame cannot exist. Also, that it is bad practice to work in atmospheres deficient in oxygen to the extent any of these analyses show.

Afterdamp

The following test shows the composition of some gas samples obtained from a mine about 18 hours after an explosion had occurred therein:

NO. 1 SAMPLE

1.37% CO_2	1.23% CH_4
0.60% CO	0.28% H_2
18.14% O_2	78.38% N_2

This sample was obtained at the face of an entry by bureau men equipped with oxygen helmets. The ventilation in this section of the entry had not been restored. The seat of the explosion was supposed to have been close to this place. A canary bird, carried by an exploring party unequipped with helmets, collapsed as it was being carried in this entry about 200 feet back from the face. The men retreated without suffering any distress. The bird revived quickly when brought back to fresh air. The sample is further interesting in that 1.23% of methane was found to be present. This particular explosion was supposed by some to have been originated by the flash of short-circuited electric wires igniting coal dust, but the fact that considerable methane was found at the face points to the possibilitiy of firedamp playing some part in the catastrophe.

NO. 2 SAMPLE

0.32% CO_2	0.19% CH_4
0.04% CO	0.00% H_2 below 0.02%
20.50% O_2	78.95% N_2

This sample was obtained in a section of the mine where ventilation had been partly restored. Even so, 0.04% of carbon monoxide was still present. Our party and others spent some considerable time in this section without feeling any effects from the whitedamp, although one member stated he did not feel very well. This man had, however, been traversing this and other sections of the mine for 7 or 8 hours; consequently it is possible that he had been breathing small percentages of carbon monoxide a large part of the time. Eight men lost their lives in this explosion, and at least six of them were overcome by carbon monoxide. Some of the rescue party also experienced narrow escapes from the afterdamp. If they had provided themselves with canary birds in the beginning of the explosion work, it is probable that a large part of the distress experienced by them would have been avoided.

Methane Apparatus

Fig. 1 shows a simple gas-analysis apparatus which has been assembled especially for the use of mine superintendents, foremen and inspectors. Methane can be determined with an accuracy of 0.1% in less than 10 min. It consists of a measuring vessel *a* for measuring the gas, and a burning vessel *b* for burning out the methane from a measured volume of mine air; *c* is the sample pipette. The mine air is drawn into the measuring vessel *a* from the pipette *c*, measured, and passed into the burning vessel *b*. The platinum wire therein is electrically heated to a white heat and allowed to remain so for 3 min. The current is then broken and the pipette cooled. The mine air is then drawn back into the measuring vessel and the contraction in volume due to the burning of the methane is determined by again measuring the sample. This contraction in volume when divided by 2 and calculated to a percentage basis gives the amount of methane present.

The measuring vessel or burette has a total capacity of 50 c.c. and is divided into the bulb at the top, having a capacity of 45 c.c., and the stem, which has a capacity of 5 c.c. The stem is graduated in 0.05 c.c. or twentieths. Water is used both in the measuring and burning vessels. The apparatus works on no new principle but follows the method adopted by Coquillon, Winkler and others who burn the methane out of a measured volume of mine air.

The Bureau of Mines has assembled other types of gas-analysis apparatus more accurate than the one described, which are, however, not simple to operate, and are meant for the use of chemists.

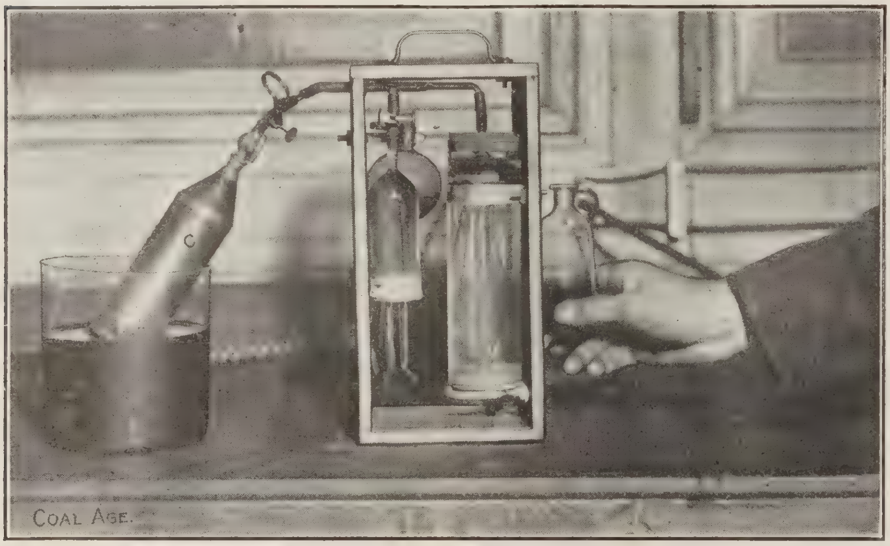


Fig. 1. Apparatus for Determining Percentages of Methane

Purchase of Locomotive Fuel Coal

By R. D. Quickel*

Frequently it is impossible for a railroad to use a certain grade of coal because it will not burn under the same conditions as other coals which are already in use, although it may be of excellent character as to its heating value, ash, sulphur content, etc. One of the worst practices in vogue today on railroads is the use of a variety of coals in a certain district or division. The locomotive fireman is the man who is chiefly responsible for the proper use of the fuel, and when he has become accustomed to using a certain grade, many kinds of trouble are frequently experienced from forcing him to use a fuel with which he is not familiar.

While it is true that railroads demand coal cheaper than any other purchaser, it must be considered that the mine having a railroad contract, is assured of business for 12 months in the year with no further expense involved.

Coal furnished on a railroad contract must first be of such a character as to enable the fireman to keep up sufficient steam to run on schedule time. There is only one way of determining whether or not the coal is of a quality to do this, and that is by actual test. Analyses are useful as indicating the character of a coal and giving some idea as to what may be expected in regard to the amount of ash, clinker, corrosion of boiler tubes, grate fingers, etc., but cannot take the place of actual trial.

When it is considered that a railroad locomotive is about as expensive a piece of machinery as it is possible to buy, that a firebox temperature of 2300 deg. F. is necessary for its proper operation, and that all the various impurities that occur in coal tend to increase the operating expenses, it is readily understood that the railroad company must take every precaution to secure a high grade of fuel.

Some operators have heretofore taken the stand that preparation of locomotive fuel was not necessary, as the railroad would take it anyhow. While the railroads have not as yet adopted the method of buying coal on a premium basis, the day will soon come when the practice of purchasing fuel by a trade name will be exceptional. The reason for this is to be found in the fact that a trade name in so many cases obviously means nothing. Railroads are sometimes accused of favoritism in regard to placing their fuel contracts with large operators. If this is the case it is chiefly because the large operator can as a rule sell at a cheaper price and can be depended upon to fill his contract. The small operator, desiring to sell fuel to a railroad, must show first that he can prepare good coal at a reasonable price and second, that he is in business for every day in the year.

The preparation of the coal is a matter of great importance in engine fuel. Some experts contend that a certain percentage of slack in a coal is beneficial. Personally, I am inclined to believe that a run-of-mine coal containing not more than 30 per cent. slack is usually satisfactory. The objection to it arises from the fact that if there are any impurities in the coal, the highest percentage is to be found in the small sizes and fine material. I have found, by actual experiment, that there is an increased consumption of 33⅓ per cent. when using a 2-in. nut and slack coal as compared with 5-in. run-of-mine. It is evident, therefore, that a large percentage of slack should be guarded against.

COAL AGE

Mine Examinations for Certificates of Competency

The question of competency of mine officials in direct charge of work in and about coal mines is attracting increased attention in all mining states. It is universally conceded that the men in direct charge of operations in coal mines should be competent to perform the duties that rest upon them by virtue of their official position and authority.

The work involved in the operation of a coal mine naturally divides itself into two or more general classes or grades of work, which may be styled as management, supervision and operation. In large companies, operating a number of plants, there are numerous subdivisions in each group, requiring general managers, managers and assistant or district managers; general superintendents, superintendents and assistant or division superintendents; general foremen, foremen and assistant foremen, and bosses, mine bosses, firebosses, boss-drivers and timbermen.

In mining work, as in all dangerous occupations, there arises the acknowledged necessity for the competent direction of work, to the end that the same may be performed with due and reasonable regard for the safety of the workmen employed.

A workman is under orders to do a certain work—he is not in a position to dictate to his boss. If a workman is unwilling to obey, because he considers the work unsafe or dangerous, it is his privilege to step aside for the man who follows. The workman may be ignorant in respect to mining work; he may be lazy and too ready with excuses for not doing the work ordered; he may be a coward and willing for the other fellow to do the hard work, the work that requires courage and skill.

It is plain, therefore, that the question of safety, as far as the company is concerned, must be decided by the mine foreman or mine boss who is there and in immediate charge of the work. He should be the *"competent"* man and the man who should be *morally* responsible for the safety of his men. We say *morally* responsible, because it seems right and just that the mine foreman or boss can only be held legally responsible for neglect or failure to perform his legal duties, while the operator or company is likewise responsible for the employment of an incompetent person, should this be shown to be the case.

Much depends, in the solution of this question, on what constitutes a "competent" person. Can competency, within the meaning of the state mining laws, be determined by an examination of candidates? If the competency of a candidate can be so determined, who should conduct the examination; and under what authority is the certificate of competency to be granted to the candidate? Finally, does the granting of such certificate of competency by a state board of examiners, duly authorized by the state mining law and commissioned by the proper officer of the state, make the state responsible for accident that may occur under the supervision of such certified person? We think not.

It might be argued with equal force that the certification of stationary engineers by a municipality, or the inspection of boilers by a city boiler inspector, makes the city responsible for accidents due to manifest incompetency on the part of such certified official; or the licensing of physicians to practice, makes the state responsible for deaths due to their mistakes.

The fact is that the city or state, in examining and certifying to the competency of candidates to hold certain positions of responsibility, is performing a gratuitous service tending to protect the lives and property of its citizens. The state or city makes no charge for the service rendered to individual operations, and no liability attaches to the government because such service is incompetent.

The question has been asked recently, "Should not the mine superintendent be compelled to pass an examination and hold a certificate of competency?" We

answer, that, in our opinion, this is not required by the exigency of the case. The superintendent is not the man in direct charge, at the point of danger. It is true he is the mine foreman's superior officer, but his province is one of supervision.

The best mining laws without exception give the mine foremen full charge and power to direct and control the ventilation of the mine and all supplies required to make the mine safe. The same law makes the fireboss the highest authority regarding the gaseous condition of the mine and gives him full power to admit or exclude men from the mine. These two officials are, therefore, the men in charge, and the law requires them to see that the mine is safe; and, for this reason, they should be certified as competent for their respective work.

In how far does the present system of conducting examinations of prospective mine foremen and firebosses serve to determine their several competency and fitness for the positions of responsibility they seek? In many cases, the law specifies that the candidate shall possess a technical knowledge of the principles of ventilation, properties of gases, methods of working, operation of mining machinery, surveying, etc. In one case, at least, which we hope and believe is exceptional, the law specifies that, "During the progress of the examination, books, memoranda, or notes shall not be allowed."

Does this law contemplate that the candidate shall memorize the formulas, constants and values necessary to pass a technical examination of this character; and is the intention of the law makers, here, to debar from the responsible positions of mine foreman and fireboss all persons who cannot memorize the formulas and tables found in every mining handbook?

Mining handbooks are for the use of practical mining men. These men should be familiar with their contents—not by memorizing the formulas and tables they contain, but by knowing where to find the formulas and values required to work any mining problem. Mine-examining boards should allow candidates the free use of any handbooks they desire to bring to an examination where technical questions are asked. The candidate uses these in mining practice, at home or in the office—why not in a technical examination?

We must not lose sight of the fact that what is needed are able and practical men, with sufficient technical knowledge to make them competent to handle the problems that arise in daily mining practice. The best practical men are not men who can memorize formulas, but who can find and use them when required. COAL AGE strongly advocates the use of textbooks in all technical examinations.

There should, besides, be one written and one oral session, in the examination of each candidate, in which no handbooks should be allowed. In the written session, questions should be asked calling for experience on the part of the person examined. In the oral session, the examination should be designed to show the quickness of the candidate to determine the best plan of action to rescue men entombed by a heavy fall; to save men and control a fire started on the main intake air-course; to control a sharp squeeze, and other like questions requiring ready answers.

The examination of firebosses should be less technical than that of mine foremen; it should aim to show the candidate's knowledge of gases, ventilation, timbering, and his acquaintance with mine maps and surveying. A sight-test should be required that would show the ability of each candidate to detect a flame cap on the common Davy lamp, and to estimate from its height the percentage of gas in the air.

In order to make mine examinations, to determine the competency of candidates, achieve their desired purpose and secure the best men, examining boards must study closely the needs as well as the conditions surrounding the men they examine. The examination is necessarily quite different from an ordinary school examination. Its aim should be to show a competent knowledge, coupled with a sufficient experience, and an ability to think and act.

Percussion

In the communication of Mr. Verner, which appeared in COAL AGE last week, he remarks that the report of the Adrian disaster published in our columns ascribed the explosion to the fall of an electric wire. But that report took no such assured stand, and while stating that "the explosion must have been due to short-circuiting of an electric-haulage wire," added, "or possibly to the leaving of dynamite or caps within the mine, despite the fact that the use of dynamite is forbidden at Adrian except for the shooting of rock headings." This is not entering a defense of anything which was contained in that article, but is rather a protest against overlooking a not improbable initial cause.

The heading, known as the 13th Left, around which the explosion centered, had run to a rock roll, and the headingmen had been using dynamite in its extension. They might have *cached* a few sticks in a neighboring room at a point beyond the support of the room pillars, and when a cave occurred, the sticks might have been detonated by the percussion.

But why not go further and admit that black blasting powder, the fuses of permissive explosives or even the powders themselves may, if exposed to a fall of roof, be exploded by either the heat, a spark or the detonation of percussion.

The use of dynamite in 1896, when the first explosion at Adrian took place, was not as common as today, and permissives were entirely unknown in the United States. It is probable, therefore, that the first explosion arose from rock falling on black blasting powder. The permissive powders have been, it is said, abundantly tested by the Bureau of Mines to determine their explosibility from mechanical detonation. Only one, which contained chlorate of potash, failed to show a perfect resistance to such action. But it is not impossible that permissives carelessly handled so that freezing or nitroglycerin exudation can take place, may be the cause of explosion, if not kept where they are free from mechanical violence.

Care should be taken always to keep explosives away from parts of the workings liable to cave.

The necessity of periodical medical examinations of the eyes of firebosses is shown by the results of such an examination conducted at the Globe colliery, Wales, England. After a disastrous explosion caused by shot firing in a gaseous chamber, it was found there was 3 to 3½ per cent. of firedamp present, which was not detected by the fireboss because of defective eyesight; the examination clearly showed that out of 41 firebosses inspected by a government inspector, 31 were found to have defective eyesight.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Geology in Coal Mining

That applied geology finds one of its most useful fields in the exploration and development of coal lands would not seem to be open to argument, yet there may be some legitimate differences in opinion between engineers and geologists as to the proper functions of the geologist and the economic value of geologic work in coal mining.

The recent article by Prof. I. C. White and one by C. P. Collins, especially relating to the controversy that led to the Ott suit against the Berwind-White Coal Mining Co., while touching upon this subject, do not properly define the functions nor the limitations of the coal geologist. The competent coal-mining engineer is necessarily a geologist and must have a good working knowledge of the district in which he is employed, but his work does not require that broader knowledge of many districts which constitutes the capital of the consulting geologist.

Having been engaged for a number of years in professional geologic work and having had equal experience as an engineer in the operation and supervision of mines, I may perhaps be in a position to express an opinion of the value and importance of geology to the coal operator and miner that will be free from personal bias; for, as a mining engineer, I am willing to restrict the geologist to his proper sphere; and, as a geoligist, I see no reason why the mining engineer should not be limited to those functions he is qualified to perform.

Geology and the Ott Suit

It is unfortunate that the Ott suit should have been used to illustrate the value of geology in coal mining. Briefly stated, the case was one in which the Berwind-White Coal Mining Co., upon having acquired the right to mine a bed of coal described in the deeds of conveyance as the "B" or "Miller" bed, were sued by Mr. Ott because he believed the company was mining coal from a bed overlying the "B" bed, and one which John Fulton believed to be the bed "C prime." The question at issue was whether the bed being worked was in reality the "B" or "Miller" bed, long known and recognized by these names along the main line of the Pennsylvania railroad between Johnstown and Gallitzin, or some other bed. Mr. Ott contended that the coal worked was too close to the surface for the "B" coal and, as stated by Mr. Collins, sunk several diamond-drill holes to learn the truth. Many geologists and engineers examined the cores from these boreholes and either failed to reach definite conclusions as to the identity of the several coals shown by these cores, or failed to substantiate their conclusions by arguments that would be accepted as proof in a court of law.

The matter was further complicated by the fact that between the region where the "B" or "Miller" coal had long been worked and recognized, and the mine in question under Mr. Ott's farm, there intervened several miles of territory in which this bed had not been opened and worked, and it was therefore impossible to trace bed "B" step by step, by mine workings, continuously from the first mentioned region to the Ott place.

Under such circumstances the identity of any bed of coal must always be largely if not entirely a matter of conjecture and not susceptible of legal proof. We know enough of the uncertainties and vagaries of coal beds to know that one may be replaced by another that normally should be found above or below it; that such a change may occur in short distances; that a bed normally thin may thicken to workable size and another normally thick may thin to small size or disappear entirely, and that the intervals between the coals, and between the beds of coal and the limestones, sandstones and other rocks, may increase or decrease in short distances, so that a bed of coal apparently found at a certain horizon may not be the bed normally present at that horizon but some other bed that is usually found higher or lower in the coal series.

Impossible to Establish Identity from Borings

To establish the identity of the coal worked on the Ott place from borehole cores therefore was manifestly impossible, and it was also impossible to prove the identity of the coal by actually tracing it through mine workings continuously from where the "B" coal was known and worked, because such workings did not exist. The actual identity of this coal may never be proved beyond question until such mine workings do extend continuously between these points.

While it was not possible to establish the identity of this coal as a legally proved fact, it was quite possible for engineers and geologists to present data that might be sufficient to convince an engineer or operator that the bed being worked was or was not bed "B."

In preparing the defense in this case the Berwind-White company placed the preparation of the evidence in the hands of Mr. Baird Halberstadt, of Pottsville, who collected a large quantity of material in support of the company's contention that the seam mined was bed "B," and other geologists were called upon to confirm and strengthen the conclusions made by Mr. Halberstadt. But it must be remembered that while in this way a great cumulative mass of evidence could be presented, all of it rested upon the personal opinion of those who had examined these data, and the result therefore could not approach the dignity of a demonstration. In the same way the conclusions reached by Mr. Fulton and those who agreed with him were personal opinions, and could not be considered as proving the truth or falsity of either view.

Distinction between Facts and Opinions

While it may seem a waste of time to go into a matter of this kind at such length, it appears to me to be justified, because it is useful to emphasize a fact of which this case furnishes a most illuminating example; namely, that the geologist should distinguish more clearly between fact and opinion, betwen proof and surmise. Possibly Mr. Collins and Mr. Halberstadt may be right in their opinion, and personally I think that quite probably they are, and possibly Mr. Fulton may be right, but it should have been apparent to all concerned that neither party was prepared to prove anything. Mining operations stretching continuously from point to point, the actual opening of the coal along its outcrop at innumerable places, or a continuous row of boreholes, would have been necessary before anything even approaching the semblance of proof could have been adduced and offered as evidence in this case.

The geologist may often be thought to have an ability to identify coal beds not justified by the history of geologic examinations, and the public may often be ready to accept an exaggerated view of his ability in this direction. The history of all attempts to identify the coal beds of different regions or localities, whether such regions or localities are widely separated or are in close proximity to each other, furnish many examples of the errors which the geologist must inevitably

make. As an illustration of this, may be cited the identification of a bed of coal in the Morrisdale-Houtzdale Basin, in Clearfield County, made by the writer in 1884, and accepted for many years by operators as demonstrating the coal in question to be the "B" bed.

After working this coal bed for many years under the belief that it was bed "B," abnormally located 30 or 40 ft. higher than its proper place in the series, it was accidently discovered that bed "B" existed below the coal worked, in its proper place and with its normal characteristics, and that the bed worked was in reality bed "C" (or a bed normally thin, lying close to bed "C"). Other instances will be found in the many changes in nomenclature and identifications made by Prof. White and others in attempting to work out the true succession and age of the coals in the West Virginia coal fields, a work that is still in progress.

GEOLOGIST VS. ENGINEER

It is extremely questionable whether in controversies of this nature either the engineer or geologist can profitably be employed by the contestants, for the character of the testimony must generally be confined to the personal opinion of the witness, supported by more or less disconnected facts, and such testimony is not usually of sufficient force to insure a final decision covering the points at issue. Recognizing these limitations many coal geologists decline to appear as expert witnesses or discourage their clients from calling them as witnesses, preferring to limit their services to the rendering of such advice as in their opinion may be of value to their clients.

In his relation to his clients, whether concerning suits at law or the development or purchase of mining property, the geologist is naturally in an advisory position and the value of his services must rest upon his ability to advise wisely. This will depend upon the nicety with which he can weigh the relative importance of all the matters at issue, including the general business and commercial conditions affecting the proposition, as well as the technical geologic facts, the opinions based upon these facts and the weight to be accorded to such opinions, and to serve his client most usefully he must be prepared to advise definitely and positively, because his client probably does not have such a sense of proportion regarding technical matters as will enable him to judge of their relative values, and is, therefore, quite likely to reach unwarranted conclusions or to be so confused by apparent inconsistencies as to be unable to form a definite opinion.

The functions of the mining engineer when engaged in an advisory capacity are well defined and are of a definite nature. He deals with the coal, ore or mineral deposit as an entity and with the quantities, qualities, costs, prices and physical and mechanical problems of mining and preparing the material for market. Unless especially qualified by geological experience his field should not include those more or less abstruse problems of applied geology, which may embrace uncertainties, conjectures and geological hypotheses and theories, for these belong to the geologist. The mining engineer properly deals with known deposits and the methods of utilizing them, the geologist with unknown and partially known deposits to determine their extent and value.

H. M. CHANCE,
Mining Engineer.

Philadelphia, Penn.

The Foreman's Trouble

In recent issues of COAL AGE, you have been rather severe on mine foremen and superintendents. I believe almost every mine foreman and superintendent looks ahead to the future successful development of his mine. Furthermore, I am sure most of us have working projections made, and lie awake nights formulating definite plans for development.

The real trouble lies in the fact that the operator is too eager for returns on his investment, and wants to curtail expenses to the lowest notch. He reminds the superintendent at every opportunity, that he must keep down expenses, and of course, the superintendent passes it down to his foreman.

I do not claim all operators do this, but there are a great many who follow such a plan. As Mr. Mooreshead mentioned in a recent issue of COAL AGE, wide entries cause falls and squeezes, resulting in heavier expenses than if they had been driven narrow. This subject is of vital importance to the successful working of a mine, and I would like to read the opinion of some other mine foreman or superintendent.

Marion, Ill. SUPERINTENDENT.

The Human Element

Since the appearance of the editorial in COAL AGE of Dec. 9, on "The Human Element," another explosion has occurred. We have the usual report that the mine was in "excellent" condition and we shall read again the same story about "the model mine blowing up." What is more, we shall continue to read "the same old story" unless some "experts" get the "dust" out of their eyes and see things in their proper light.

It is true that "careless and vicious men find their way into the best of mines" and they are undoubtedly a menace, but that menace is fairly universal and it may be assumed that these "careless and vicious men" are just as plentiful, and perhaps more so, in mines badly arranged and poorly managed.

I have a fairly complete record of mine explosions in the United States for the last 23 years, together with the conditions under which they occurred, and I have not found a single case in all these years where an extensive dust explosion occurred in a badly arranged and neglected mine, while, on the other hand, the record shows that the most violent and extensive explosions have taken place in mines that were—like the Briceville mine—in excellent condition.

These are facts and it would be rank slander to assume that the "experts" were not aware of their existence, but, knowing about them, the "experts" so far have failed to offer an explanation as to the cause. Why? It would be interesting, at least to some of us, to know the reason.

JOHN VERNER.

Chariton, Iowa.

Fair Play for the Mule

In the last issue of your paper, I note the article on "Fair Play for the Mule," by Joseph Virgin. In reference to the remarks he makes, relative to Eli Conner's recent article, I may say that while I believe that Mr. Conner's comparison of mechanical and mule haulage refers to actual experience at Ehrenfeld, it does not do so exclusively.

When gathering motors were installed at the Sun mine, in the New River field, I held the position of district superintendent, under Mr. Conner. At that time he advanced the same argument as Mr. Virgin, but I believe the performance of the motors in that mine did much to change his views.

If Mr. Virgin will compare the expense necessary to keep up mule haulage with that needed to maintain a motor haul in the same place, I believe he will find it is rather costly to give the mule "fair play"—especially if the bottom be fire clay and the road a little damp.

After a mule has tramped on a switch bridle, that switch is not much better, if as good, as the stub switch, which is generally used with mule haulage.

In making the comparison we must add the cost of the maintenance of the mule to the upkeep of the road, and keep in view the fact that the speed and the endurance of the motor enable it to transport the cars a greater distance than they could be hauled by a mule.

If we sum up the whole cost of giving the mule fair play, I believe we will find the account will show a balance in favor of gathering motors. In my estimation the place to give the mule fair play is on the farm, not in the mine.

INQUIRIES of GENERAL INTEREST

A Page Devoted to Those who want Information. All Questions must be Accompanied by the Name and Address of Inquirer

Preservation of Steel Rope

Is coal tar, after being treated with freshly slaked lime, injurious to steel-wire haulage rope? Will it cause the wires to become pitted, and could it possibly cause crystallization to take place in the wire?

Bella Ellen, Ala. SUPERINTENDENT.

This question is of great importance to all users of wire rope, in mine-haulage practice, and was submitted to the manufacturers of wire rope, in this country. Following are the replies received.

"Either coal tar or pine tar can be used on wire rope without detriment, provided the tar is first neutralized by boiling with freshly slaked lime. Unless the tar is thus completely neutralized, the acid, which it contains, will attack the steel, and cause brittleness.

"We do not advocate the use of tar, however, on running ropes, for the reason that it is practically impossible to thoroughly seal a rope in this manner. The tar hardens and strips off or cracks, allowing moisture to reach the rope, causing it to rust under the tar. We consider it is better to use a lubricant free from acid, and one that will penetrate the rope and preserve the inner wires, which are, after all, the reserved strength of the rope. We have found that many users who have covered or partly covered the outside of the rope with a heavy dope are, later, surprised to find that the inner wires have become corroded and lost their strength. It is best, in treating a wire haulage rope, to start with a lubricant that will penetrate, and then build up so the inner and the outer wires alike will be protected."

JOHN A. ROEBLING'S SONS CO.

Trenton, N. J.

"In the process of drawing wire, lime is used as a coating to protect the surface of the wire from corrosion. If a steel rope, coated with a mixture of coal tar and slaked lime, becomes pitted it cannot be due to any action of the lime, but rather to its insufficiency; or the fact that it has not been mixed so as to thoroughly neutralize the acids in the tar.

"We do not, however, advocate a mixture of coal tar and slaked lime as a coating for wire ropes, as it flakes off when dry. The compounds of pine tar are better, and those of crude petroleum and graphite better still. In this connection we draw attention to page 11 of our booklet, 'Wire Rope Preservatives.'"

THE TRENTON IRON CO.

Trenton, N. J.

"We would advise that a composition of coal tar and lime is not injurious to wire ropes.

"Some years ago, before the advent of special lubricating greases, a composition of coal tar and lime was recommended by wire-rope manufacturers.

"It is probable these people have had trouble with sulphur water, which penetrated between the strands of the rope and pitted the steel. If the crystallization spoken of took place it might result from the action of the acid water on the steel, which destroys the structure of the steel and makes it brittle. The coal tar and lime could not produce this effect."

HAZARD MANUFACTURING CO.

Wilkes-Barre, Penn.

[We believe the above letters answer our correspondent's query fully and, in his behalf, we wish to thank the writers for the explanation.—EDITOR.]

Wet Rag in Afterdamp

I note that in your issue of Nov. 18, in the article on the Adrian Mine Explosion, you state that "two men had enough presence of mind to stop, dip their handkerchiefs in the tea contained in the tanks of their dinner pails and carefully wrap their mouths with the damp rags." What is the action of such a covering over the mouth?

PUZZLED SUBSCRIBER

Punxsutawney, Penn.

The question is a hard one and your letter suggests that you have realized its difficulty. It will probably not be news to you that the method of using a wet rag or sponge is one which has been repeatedly tried and found availing in work where air is vitiated. Doubtless you have also read that old explanation that water dissolves carbon dioxide, and so makes the air respirable. But as you may have considered, water only feebly dissolves carbon monoxide, and so that action is probably not one of solution or it would be without efficacy in excluding the most poisonous of the gases encounted. In fact, the order of solution in water at 68 deg. F. is:

ABSORPTION FACTORS FOR MINE GASES

Carbon dioxide	0.90100
Oxygen	0.03137
Carbon monoxide	0.02320
Nitrogen	0.01599

Moreover, the action of carbon dioxide is now realized to be objectionable rather as it replaces oxygen in the air than for any other reason. If 10 per cent. of CO_2 is absorbed, the percentage of oxygen will be increased one ninth of its former value. If 9 per cent. of oxygen is present the wet rag absorbing the last molecule of dioxide would only make that proportion 10 per cent. So the absorption of carbon dioxide but little improves the mixture.

An ordinary bandanna measuring 15x21 in., a common size, was compelled to absorb all the water which it was capable of lifting from a measured volume of the liquid. A reasonable amount of the loose water was permitted to run back into the measure, the kerchief being held meantime by two of its tips. The loss of water in the original receptacle was then measured. To keep on the safe side it is assumed that the kerchief water is wholly available for inspiration, that it does not evaporate, is not absorbed by the person of the wearer and does not seep out later on. The amount of water engaged by the bandanna under such assumptions is 5 cubic inches.

We assume that the air is vitiated by 10 per cent. of CO_2, or 10 per cent. of CO, not an unreasonable amount, for the percentages might be well imagined nearly doubled without improbability. We assume moreover, that the temperature is 104 deg. F. The normal inspiration as stated by J. S. Haldane, is 432 cu.in. per min. This figure for inspiration is also assumed correct, although Doctor Haldane states that during muscular exertion, the volume of air breathed may be 6 or 8 times as much as during rest. Thus in one second 0.72 cu.in. of CO_2 and an equal volume of CO would be inspired. From these facts the table following is made up, the coefficients of absorption used being those of gas at 104 deg. F.

TIME OF GAS SATURATION OF WET BANDANNA

Gas	Coefficient of Absorption	Cubic Centimeters of Gas Absorbed by Kerchief	Time for Complete Saturation Secs.
CO_2	0.506	2.53	3.51
CO	0.018	0.09	0.12

It is clear that the handkerchief does more than dissolve the gases mentioned, because if that was all it accomplished, it could only serve a fleeting purpose.

EXAMINATION QUESTIONS and ANSWERS

There is nothing better for gaining such information than a good, technical mining weekly.—Editor.]

First-aid Methods

Ques.—What is the correct method of procedure in regard to the first-aid treatment to be given persons injured and suffering from (a) burns; (b) electric shock; (c) broken limbs; (d) bleeding from cuts or wounds; (e) being overcome with gas? Explain fully.

Ans.—In all cases, keep cool; send promptly for a physician and, when possible to do so without danger, remove the sufferer to a quiet place and good air.

Treatment of Burns

(a) Remove clothing from the burned parts by cutting away the cloth carefully; and quickly cover the burned surface with light, soft linen or a layer of absorbent cotton to exclude the air. If possible, moisten the parts burned with a warm solution of common baking soda, or an emulsion of boiled (linseed) oil and limewater. Uncover but a small portion of the burn at one time. Do not expose to heat, and protect from dirt.

Treatment of Electric Shock

(b) A brief contact with, say a 250-volt current, may give a severe shock to the nervous system that will pass off shortly. A more prolonged contact produces unconsciousness or death, depending on the individual, the quantity of current and its passage through the body. A strong man may resist successfully a current that would be certain death to a man with weak heart or nerves. If the current passes through the body its effect is greater than that produced by the passage of the same current through the legs only.

Shut off the current, cut the wire, or by any means remove the person from the contact as quickly as possible. It may be possible to short-circuit the current and blow out a fuse. To remove a person from contact, a kick is often safer, because the current then only passes from one leg to the other, instead of through the body. Stand on a dry board or paper; if at hand, use rubber shoes or gloves, or both. Act quickly; a few seconds may prove fatal.

When contact is broken, lay person on his back; loosen the clothing about the neck, chest and waist; give plenty of fresh air; but avoid cool drafts, as the body should be kept warm.

If respiration has ceased, artificial respiration must be begun by drawing the tongue forward with handkerchief so that it will not obstruct the windpipe, and kneeling at the patient's head raise his arms first straight above his head; then throw them forward, bending the elbows and pressing the arms firmly against the sides and chest, to expel air from the lungs. Continue to work the arms, in this manner, forward and back, as a bellows, till natural breathing is restored. If the heart has ceased to beat, sometimes a sudden rap on the left chest will start its action, which must be done promptly or death is certain.

In all cases where artificial respiration is used, efforts to restore the patient to consciousness should not be discontinued till after a long time and when every possible means has been exhausted.

Treatment of Broken Bones

(c) Move the patient with great care to as comfortable a position as possible, but do not attempt to carry him far if the fracture is painful or the bone is broken badly in one or more places. If the limbs are broken bind them together or to the body in such a way that the removal of the patient to a more desirable place will not aggravate the trouble. If necessary to remove clothing cut it away and do not pull it off. It will often be necessary to improvise a stretcher by running two long drills through the arms of two or more coats; or to bind the patient firmly and carefully to a brattice board or to two lengths of tracking tied together. Every move must be made gently. Then remove the sufferer to where he can be treated by a physician. Do not attempt to set a bone, but only make the patient as comfortable as possible till a physician arrives.

To Arrest Bleeding from Cuts or Wounds

(d) Lay patient down, generally on his back, and elevate, as far as can be done, the limb or part of body from which the blood is flowing. Apply pressure to the bleeding parts, with the thumb and fingers; or by a knotted bandage, the knot being arranged to press the wounded part so as to impede and stop the flow of blood. If the blood is a bright red and spurts more or less from the wound, an artery has been severed, and the pressure must be applied to the blood vessel somewhere between the wound and the heart. Venous blood flowing from a vein is a darker color and wells up or flows steadily from the wound.

Keep the body warm, if necessary using hot-water bags or compresses; but in severe bleeding it is often necessary to apply ice or a cold iron immediately over the wound, to assist the coagulation of the blood.

Treatment of a Person Overcome with Gas

(e) Remove the patient speedily to fresh air. If unconscious, keep body warm; dash cold water over face, from side, so as not to obstruct the nose. If necessary, employ artificial respiration to restore breathing. Give no stimulants; but peroxide of hydrogen, diluted with an equal quantity of water, is beneficial if the gas inhaled is carbon monoxide (CO). Rub the limbs upward briskly, to assist the flow of venous blood back to the heart and induce circulation. The inhalation of oxygen is always used with good effect to drive the poisonous gas from the lungs.

Every mine of any considerable size should have a well equipped hospital. The hospital should be convenient to the workings and not too far from the shaft. It should be well ventilated and oxygen tanks should always be kept on hand ready for use.

Combustible Material in Mine Entries

Ques.—What should be done with torn, unused brattice cloth found lying in the entries or the workings of a mine?

Ans.—Brattice cloth and all other combustible material not in use should be removed from the mine, if it cannot be used again. If it is good for further service it should be stored in a suitable place either in a mine shanty or a storeroom on the surface. It should not be allowed to accumulate in the entries or other parts of the mine.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Representative Palmer has introduced a bill revising the Bureau of Mines Act which has been referred to the House Committee on Mines and Mining. In this it is proposed to amend section 2 of the act to read as follows:

"It shall be the province and duty of said bureau and its director, under the direction of the Secretary of the Interior, to make diligent investigation of the methods of mining and quarrying in slate, cement rock, granite, and other quarries, especially in relation to the safety of miners and other operatives, and the appliances best adapted to prevent accidents, the possible improvement of conditions under which mining and quarrying operations are carried on, the treatment of ores and other mineral substances, the use of explosives and electricity, the prevention of accidents, and other inquiries and technologic investigations pertinent to said industries, and from time to time make such public reports of the work, investigations, and information obtained as the Secretary of said department may direct, with the recommendations of such bureau."

Segregated Coal and Asphalt Lands

Representative Carter has offered a bill to provide for the sale of the surface of the segregated coal and asphalt lands of the Choctaw and Chickasaw nations and for other purposes. In this it is provided that there shall be an appraisal of the lands. Section 1 specifies that "the coal or asphalt deposits in each lease shall be appraised separately from the surface" and "the unleased coal and asphalt deposits shall be appraised separately from the surface according to the tracts used by the United States Geological Survey."

It is further provided that each holder of a coal or asphalt lease shall have the right to purchase at the appraised value a sufficient amount of the surface covered by his lease to embrace improvements, up to a maximum of 10 per cent. of such surface, subject to certain conditions and the approval of the Secretary of the Interior.

The methods of entering upon the lands for the purpose of prospecting are described and section 5 of the bill directs that the sale shall be carried on at public auction. The sum of $50,000 is appropriated for expenses.

Domestic Coal Locations in Alaska

Senator LaFollette has offered a new bill (Senate No. 3124) in which he proposes to amend the bill of the same number already introduced for the purpose of regulating the leasing of coal and coal lands in the territory of Alaska, which he presented last session.

The bill is of considerable importance because it indicates a decided change in the program of the progressive group in Congress with reference to the treatment of the Alaska coal lands. The new bill proposes to strike out section 8 of the measure already proposed and provide that any citizen of the United States duly qualified may, under the same conditions as in the case of placer claims "secure a domestic coal location for a period of ten years and no longer, which location shall give a right to the exclusive possession for coal-mining purposes only of a rectangular area of unappropriated public coal land in Alaska not exceeding ten acres in area nor larger than a square of ten acres in any dimension.

"A domestic coal location shall not be staked or recorded except by the locator in person, and shall not be sold, leased, hypothecated, or otherwise disposed of. The coal mined from any such location shall not exceed 2000 tons in any one year, shall be subject to no royalty, and shall not be exported from Alaska. Domestic coal locations may be made immediately upon the passage of this act, notwithstanding any existing withdrawal of coal lands, but subsequent withdrawals shall be effective as against such locations, unless the same shall be specifically expected therefrom."

Government Railroad for Alaska

A new section, also to be added to the bill, reads in part as follows:

"The President shall cause the construction and operation of a railroad from the Matanuska or Bering River coal fields in Alaska to the coast. The Secretary of War is hereby directed without delay to examine all existing surveys for railroads from the Matanuska and Bering River coal fields in Alaska to the coast, and if it shall appear that the probable cost of constructing a coal-carrying railroad from one of said coal fields to a harbor open all of the year is less than half the probable cost from the other of said fields to such a harbor, then the Secretary of War shall proceed forthwith to locate a railroad on the best practicable line along or near the route so determined to be less costly."

Alabama

Birmingham—A decree was recently rendered by Judge W. I. Grubb, denying the petition of the St. Louis Trust Co., as trustee for the J. H. Mudd estate, for an injunction to terminate the lease of the Galloway Coal Co. and restrain the company from operating its mines on certain lands in Bibb County. It is reported that the Galloway company contemplates making various improvements on the Bibb County coal lands, which improvements will probably be carried forward now that the suit over the land has been settled.

The new byproduct coke ovens of the Tennessee Coal, Iron & R.R. Co. are nearing completion. It is intended to fire the first battery of these ovens early in January.

Gadsden—The property of the Raccoon Mining Co. at Altoona, will be put in operation, after a long shutdown. About 100 men will be employed.

Colorado

Denver—The Colorado coal fields are now the only coal-mining districts in this country or Canada where labor troubles of any magnitude remain unsettled. Although the mines in both the Northern and Southern fields continue in operation, the condition in the former is one of suspended hostilities and in the latter field it is reported that a strike is imminent. The operators of northern Colorado openly charge Gov. Shafroth with favoring the cause of the strikers and neglecting to take proper measures to secure the peaceful and unmolested operation of their mines. In the Southern field, the report of a commission appointed by the governor, which shows the men to be losing 2½c. per ton on an average because of the change from a lump-coal to a run-of-mine basis of payment, has revived the dispute which caused the threatened strike of 1000 employees of the Colorado Fuel & Iron Co., last October. Although not previously a union field, it is reported that the men have recently become generally organized and a strike involving perhaps 20,000 workers is probable.

Agitation by the Denver Chamber of Commerce directed toward securing a

lower price for coal and recommending the operation of mines by the state, has elicited from President Evans, of the American Fuel Co., an offer to sell that company's property to the state at 50c. on the dollar. Mr. Evans is so strongly of the opinion that coal cannot be produced and sold more cheaply than it is at present that he declares that this offer is made in perfectly good faith and stands.

Illinois

Chicago—An executive meeting of the coal-mine operators of the Illinois and Indiana coal fields was held in Chicago, Dec. 14. The meeting was for the purpose of conferring with the Ohio and Pennsylvania operators, but it was unofficially declared that the latter delegations had not arrived, it being said that these two states are opposed to entering into an agreement. Another meeting was arranged for, to be held in Columbus, Ohio, within 10 days.

Isaac A. Smith, who is interested in the proposed Springfield & Central Illinois Traction Co., reports that it is probable that the proposition as outlined, which is to connect with several mines in the central Illinois field, will go through within a short time.

Taylorville—The Peabody Coal Co. is developing three mines, in the vicinity of Taylorville and Kinkaid. Work on all three is now reported to be in progress. It is understood that a large central electric plant will be located at Kinkaid.

Marion—A charter has been granted to the Johnson City Connecting Railway Co. It is proposed to construct a railroad in Williamson County, connecting several of the mines in the vicinity of Johnson City and Marion.

Indiana

Indianapolis—Chairman Wood, of the state railroad commission, has issued an order amending the car demurrage rules to except from demurrage the cars loaded with coal or coke and awaiting transportation at the mines or coke ovens. Before the amendment, only those cars at the mines or ovens which were waiting to be loaded were excepted. The order, which was made without objection by any of the roads, was asked for by the Vandalia Railroad Company.

Members of the United Mine Workers of America balloted, Dec. 12, for their national officers. The most important contest was for the office of president, John P. White, of Oskaloosa, Iowa, being opposed for reëlection by Thomas L. Lewis, of Bridgeport, Ohio, a former president of the organization. Edwin M. Perry, of Iowa, had no opposition for reëlection as secretary-treasurer, but there was a large number of candidates for other offices. The results will not be officially announced until the convention in January.

Terre Haute—The formation of a national federation of bituminous coal operators is understood here to be an assured fact. The appointment of a committee on organization and constitution at a recent meeting has been announced. Philip H. Penna, secretary of the Indiana Bituminous Operators' Association, said that the national organization had been in the course of formation for several years, and that final steps were taken last week at Chicago. Mr. Penna said that assurances have been received that every coal-producing state in the Union will be represented.

Kentucky

Louisville—The Elkhorn coal field is to have another railroad, one with an eastern and southeastern outlet. The Carolina, Clinchfield & Ohio will start from St. Paul on its main line in Wise County, and pass through Coeburn, Norton, Glamorgan, and the Pound section in the Virginia coal fields; through Pound Gap on the state border by a short tunnel, and so on to Jenkins, connecting there with the Big Sandy & Elkhorn, a branch of the Chesapeake & Ohio, now being rapidly constructed into Jenkins.

At the midwinter meeting of the Kentucky Mining Institute, held at Lexington, Dec. 11, a number of owners, managers and general superintendents of coal mines were present. Vice-president R. B. Hutchcraft presided. Appropriate resolutions regarding the death of President Atkinson were adopted. A number of papers, dealing with the practical operation of mines, were read and discussed.

If the plans of Eastern capitalists, headed by Gen. T. Coleman Du Pont, of Wilmington, Del., who are conferring with the owners of several coal mines in southwestern Kentucky, go through, a coal merger, estimated to involve $10,000,000, will be completed. The coal companies to be taken over are the W. G. Duncan Co., the Powderly Coal Co., the Lam Coal Co., the Wickliffe Coal Co. and the Memphis & Broadway Coal Co. According to the terms of the consolidation, the control must pass from the Kentucky operators to the Eastern capitalists.

Missouri

St. Louis—The top works of the mine of the Northern Central Coal Co., at Higbee, were destroyed by fire on the night of Dec. 12. The output of this mine was largely contracted to the Chicago & Alton for company fuel.

The St. Louis Coal and Coke Company has been incorporated for $50,000. It will handle the output of the Colp Mine at Pittsburg, Ill., the Gent Coal Company's mine near Marion, and the Galatia Coal Company's mine at Galatia.

Nevada

Goldfield—Great interest is being manifested in the development of the coal mine at Coaldale, 60 miles north of here. An analysis of several samples of the coal shows it to contain about 50 per cent. fixed carbon and 33 per cent. volatile matter. The property is being worked by a slope 150 ft. long which taps the coal at a depth of 80 ft. below the surface, the seam varying from 8 to 11 ft. in thickness. Indications are that the deposit covers a considerable area and it is thought probable that the Tonopah & Goldfield R.R. will build a spur to the property.

Ohio

Cleveland—It is understood here that the proposed $30,000,000 coal merger in No. 8 field, Ohio, is likely to prove a failure on account of the Ohio anti-trust laws and other unexpected obstacles. W. F. Kann, of Pittsburg, is representing the operators and F. J. Lisman & Co., of New York, are in charge of the financing. The company was to have issued $10,000,000 preferred stock, $5,000,000 common stock and $15,000,000 bonds.

Columbus—The Eastern Ohio Coal Operators' Association appeared before the Interstate Commerce Commission, Dec. 13, against the Wheeling & Lake Erie, the Baltimore & Ohio, and the Pennsylvania Lines West of Pittsburg, charging that the rates on coal from the mines in eastern Ohio to Lake Erie ports are unjust and discriminatory. The present rate is 85c. a ton on all three roads and the association, which is composed of 40 individual operators, is willing to leave the commission to decide on what it considers a fair rate.

The Black Top mine, in the Crooksville field, will not be reopened until after Jan. 15, if then, according to State Mine Inspector Harrison, who recently inspected the mine. A portion of the mine was sealed up after a recent fire, and samples of air taken through tubes inserted in the wall show the presence of considerable gas.

Toledo—By the terms of two decisions handed down by United States Judge John M. Killits, Dec. 9, the Hocking Valley R.R. Co. must answer to indictments of having granted rebates to the Sunday Creek Coal Co., and the latter concern must stand trial on the charge of having received rebates. The summary of the opinion is that the granting of unlimited credit by the issuance of notes to guarantee freight charges is a violation of the Elkins anti-rebate law, and both the grantor and the firm accepting rebates are guilty.

Cincinnati—Commencing Dec. 1 the Burlingham Coal Company, of this city, has secured control of the St. Clair col-

liery, at Eagle, W. Va. A new operation will be opened on the property, which is on the Chesapeake & Ohio railroad. Louis Watkinson remains as president of the company and will continue in charge of the operations.

Oregon

Portland—H. S. Brinley, of Portland, has taken a lease on an 8-ft. vein of bituminous coking coal recently uncovered on the property of the Benedictine Fathers, near Mount Angel, Oregon.

An important strike of bituminous coal is reported from the Rainy Hollow district near Haines, Alaska. The vein is said to extend across the British Columbia boundary.

Pennsylvania

Bituminous

Westland—The Midland No. 3 mine of the Pittsburg Coal Co., employing nearly 400 men, closed down, Nov. 29, for the winter. Some of the men are being employed at the Midland No. 1 and the Allison mines of the same company, while the others are being employed in the Ohio and West Virginia coal fields.

Pittsburg—Delegates from 45 branches attended the meeting, Dec. 14, of the River Coal Employees' Relief Association of the Monongahela River Consolidated Coal & Coke Co. The financial report of the association was read and officers elected for the ensuing year.

The Coal Mining Institute of America held its winter meeting in the quarters of the Engineers' Society of Western Pennsylvania, this city, Dec. 19 and 20. In addition to addresses by the presidents of the two organizations, eight interesting papers were presented.

Following a conference of coal operators and electrical experts with Chief Mine Inspector James E. Roderick, held recently at Pittsburg, Supt. W. R. Calverly, of the Berwind-White Coal Mining Co., has appointed a committee of mining and electrical engineers to agree upon a uniform system of indicating on maps electrical equipment used in the mines of the bituminous regions of western Pennsylvania.

It is announced that the West Penn Traction Co. will build a line connecting West Newton and Hunker, a distance of 10 miles. The company will then need but four more miles of road to give it a continuous right of way through the coke regions from McKeesport to Scott Haven.

Immediate improvement of the Allegheny River from its mouth to the Mahoning Creek, a distance of about 60 miles, by the construction of five locks and dams is the recommendation of Col. Newcomer, resident engineer at Pittsburg, to the chief of engineers, made public, Dec. 14. For this work it is estimated that an appropriation of $2,500,000 will be required. The improvement of the Allegheny will have to wait specific appropriations, which may be included in the forthcoming river and harbor bill, or may be delayed in view of the already heavy appropriations for the Ohio.

Anthracite

Scranton—The Carlton Coal & Mining Co., recently incorporated, is reported to have begun work at an abandoned property, leased from the Lackawanna company. There is still considerable coal in the old workings, including a large number of pillars. A small breaker has been erected.

Wilkes-Barre—The anthracite conciliation board met here, Dec. 11. The grievances of the employees of the Alden Coal Co. were taken up, and, with one or two exceptions, the miners were sustained in their complaints. The award is retroactive and means back pay for the men, dating from Aug. 1, 1911. Grievance No. 201, preferred against the Lehigh & Wilkes-Barre Coal Co., was continued over to the next meeting.

Two serious cavings of the surface occurred recently in this vicinity; one at Plains, where an important street crossing subsided about 2½ ft., and one at Courtdale, where the Kingston Coal Co. has recently expended a considerable sum to strengthen the mine workings against caving. In both instances a number of houses were disturbed and damaged.

Lansford—One of the largest operations in the anthracite field was started recently by the Lehigh Coal & Navigation Co., when a force of men began work on sinking a shaft which will eventually tap six veins of coal and mean the erection, near Hauto, of a mammoth new breaker.

It was announced, Dec. 12, that the Lehigh Coal & Navigation Co. will issue $3,000,000 of collateral trust 4½ per cent. bonds for the purpose of financing an electric power plant, which will utilize waste coal. The new plant will be located near Hauto, about eight miles above Mauch Chunk, along the Nesquehoning Creek, and will involve the construction of a new dam to increase the capacity of an existing reservoir.

Shenandoah—The main steam pipe, 15 inches in diameter, that carries steam from 20 boilers at Maple Hill Colliery, exploded recently, demolishing the roof and one side of the boiler house. Three men barely escaped from being struck.

Tennessee

Knoxville—Frank White and others have purchased the leasehold and improvements on 800 acres of coal lands from the Valley Creek Coal Co. The property is on Clear Fork, adjoining that of the Pruden Coal & Coke Co. Mr. White states that an organization will be perfected and the mines operated.

According to the latest available reports from Briceville, 46 bodies have so far been recovered in addition to the five men who were taken out alive from the Cross Mountain mine. Dr. J. A. Holmes has left the rescue work in charge of J. W. Paul and Dr. Rutledge.

Washington

Spokane—As the result of a decision recently handed down by the U. S. Supreme Court, which declares that a person or association is limited to one coal-land entry in Alaska, trials will be begun at the next term of the federal courts which may involve the title to lands valued at many million dollars.

The Northwest Coal Co., of North Yakima, is making preparations to develop a large bed of coal in the Taemun Creek basin. Charles Wickle is manager.

West Virginia

Welch—The grading for the new mining plant of the Pocahontas Consolidated Collieries Co., on the South Fork of the Tug River, is completed, and as soon as the railroad is laid to the mines, operation will be commenced.

The electric plant of the Pocahontas company, located at Switchback, which in addition to furnishing power for the Collieries plants, supplies the Appalachian Power Co., selling power to the towns of Pocahontas and Bramwell, will be increased to meet the new conditions. The Collieries Co., as well as the towns of Pocahontas, Bramwell and other towns and various coal plants, will eventually secure power from the Appalachian Power Co's hydro-electric plants which will be established as soon as the dams being erected by the company in Carroll and Grayson Counties are completed.

Canada

Alberta—The Superior Coal Co., capitalized at $1,500,000, has been launched by B. K. Bullock, well known in coal-mining circles in this province. The property is situated 3½ miles from Tabor, just north of the Belly River. Development has been going on steadily for some time and already two tipples have been erected, approximately one mile apart. An area of 5043 acres was purchased from Osler, Hammond & Nanton, of Winnipeg. The seam is 4 ft. 2½ in. thick, with a minimum of shale, making the work of mining a comparatively easy matter. A test of the coal shows it to contain 46 per cent. carbon.

Nova Scotia—The properties of the North Atlantic Collieries Co. were sold under execution at Sydney, Dec. 14, for $70,500, to H. C. Foss. It is understood that they were purchased for Stone & Webster, of Boston, Mass.

Personals

Edward Savage, of Pittsburg, Penn., has succeeded Lowther Ferris as sales agent of the Carnegie Fuel Co., in Minnesota and Wisconsin.

George Z. Hosack has resigned as vice-president of the Pittsburg Coal Co., effective Dec. 31. Mr. Hosack will become president of a new company, known as the Cross Creek Coal Company.

J. G. Skidmore, of the Madison Coal Corporation, has been elected president of the St. Louis Coal Club, a recently organized association of coal men in and about St. Louis. A. A. Bryden, Borders Coal Co., is vice-president and E. J. Wallace, Missippi Valley Fuel Co., is secretary and treasurer.

F. E. Doubleday, general manager of mines for the Central Coal & Coke Co., Pittsburg, Kan., has resigned, effective Dec. 1. He has been succeeded by William McKinley, who has been a superintendent of mines for the company for a number of years, most of the time in the vicinity of Huntington, Arkansas.

H. S. Geismer, who was recently appointed one of the receivers of the Chattanooga Iron & Coal Co., is a member of the Keiser-Geismer Engineering Co., of Birmingham, Ala., and until lately was superintendent of the Tennessee division of the Southern Iron & Steel Co., operating the Chattanooga furnace and the Dunlap mines.

Capt. W. A. May has been elected vice-president and general manager of the various coal companies controlled by the Erie. These are the Pennsylvania Coal Co., the Hillside Coal & Iron Co., the Northwestern Mining & Exchange Co. and the Blossburg Coal Co. Since the Erie took possession of the Pennsylvania Coal Co., Capt. May has been acting as general manager.

Obituary

David W. Howie, Sr., aged 69 years, died suddenly Dec. 7, at the home of his daughter in Milwaukee, Wis. Mr. Howie was prominently identified with the Milwaukee coal trade, having been a coal dealer in that city for the past 30 years.

Hugh Coll, for many years superintendent in charge of water supply for the H. C. Frick Coke Co., died Nov. 29, at Easton, Md., after a brief illness from typhoid fever. Mr. Coll was a member of the Frick Veterans' Association.

Col. J. B. Stephenson died at his home, in Roanoke, Va., Dec. 5. Of late years Col. Stephenson had not participated actively in business. He was a man of considerable wealth, having invested a number of years ago in coal lands, which have since become the property of the Pocahontas companies, and have yielded a large revenue.

Construction News

Myersdale, Penn.—Frank B. Black and associates have purchased a large tract of coal land lying on the Negro mountain ridge between Garrett and Wilson Creek, with a view to beginning operations in the near future.

Birmingham, Ala.—It is reported that certain improvements which the Galloway Coal Co. have contemplated making on their property in Bibb County will probably be carried forward now that litigation in regard to the lease has been settled.

Knoxville, Tenn.—The Southern Mining Co., Williamsburg, Ky., which recently leased the operations and coal-land holdings of the Asher Coal Mining Co., of Wasiota, Ky., is said to contemplate spending about $500,000 in developing and equipping the mines.

Blairsville, Penn.—W. P. Graff, R. M. Smith and associates, of Blairsville, have purchased a 250-acre tract of coal land from the Isabelle Furnace Co. and will immediately make preparations to mine coal. This is a Cokeville operation which the steel corporation shut down about 10 years ago.

Somerset, Penn.—The Quemahoning Creek Coal Co., Charles J. Harrison, Somerset, president, is opening a new mine between Somerset and Jenners. The company will erect an up-to-date tipple and install electric mining machinery. Thomas Daly, of Grafton, W. Va., is consulting engineer in charge of construction.

Norfolk, Virginia—It may be stated positively that both the Norfolk & Western and Chesakeake & Ohio railways will build this year new coal piers, modeled after the Virginia Ry. pier, but embodying such changes and improvements as may seem advisable. Both of these new piers will be used exclusively for loading steamships and will add greatly to the dumping facilities at Hampton Roads. It is expected that arrangements will be made at the new piers to prevent the excessive breakage of the coal, which is one of the chief objections to the old style piers.

Recent Incorporations

Kentucky—The Clover Fork Coal Co., of Harlan; capital $50,000. In corporators: A. F. Whitfield, Cyrus Whitfield and B. W. Whitfield.

Arkansas — The Hartford Smokeless Coal Co., of Little Rock, capital stock $6000: Incorporators: C. B. Blackburn, John W. Tyler and O. C. Hansen.

Texas—The Southwestern Fuel Co. of Fort Worth; capital stock, $60,000. Incorporators: Herman L. Smith, Thomas D. Ross and Francis A. Douglass.

West Virginia—The Jolliffe Coal & Coke Co., of Fairmont, capital $150,000, has been chartered to operate in the Lincoln district of Marion county. The incorporators are Jacob S. Hayden, M. A. Jolliffe and associates, all of Fairmont, W. Va.

The Gascoaloil Co., of Charleston; capital $25,000; to deal in and develop mineral lands in the Big Sandy district of Kanawha County. Incorporators: D. B. Brawley, D. A. Brawley, W. B. Brawley, H. D. Brawley and R. M. Brawley, all of Charleston.

The Spruce Fork Coal Co., of Charleston; capital $400,000 to do a general coal-mining business, operate byproduct plants, cut timber and manufacture lumber in Logan County. Incorporators: William M. Humphreys, Jr., J. Keating Willcox, J. L. Montgomery, Frank L. Whitley and T. Truxton Stiles, Jr., all of Philadelphia, Penn.

Columbus, Ohio—The Hemlock Co., of Columbus; capital, $50,000; to mine and sell coal and prospect for oil. Incorporators: N. C. L. Kachelmacher, R. A. Magly, F. R. Anderson, C. B. Donahue and M. Burke.

Industrial Notes

Brown Brothers, of Elmira, N. Y., established for 18 years in the woodworking industry, announce a wood-pipe department equipped with every modern device. Max M. Brown, widely known in the coal industry, will be in charge of the field sales work, assisted by Col. Archie E. Baxter, Benj. B. and Paul B. Brown. J. C. Brown, inventor of various types of woodworking machinery, will handle the producing end. High class stock and extra lengths will be specialties of the new pipe-manufacturing department of this concern.

The Ottumwa Box Car Loader Co., of Ottumwa, Iowa, has completed the building of a modern coal-mining plant at the Acme property of the Acme Coal Co., Sheridan, Wyo. This plant is one of the largest and most uptodate installations west of the Mississippi River. It consists, in part, of a steel tipple containing shaker screens, automatic feeds, weigh pans, scales, etc., which prepares four sizes of coal for loading directly onto railroad tracks. The mine cars are brought to the tipple from the mine level on a steel approach and are handled by a modern car-haulage system. When market conditions so require, all sizes of coal, except lump, are carried from the tipple to a rescreen house by means of a 30-in. belt conveyor supported on steel trusses. The rescreen house is equipped with a revolving screen for preparing five sizes of coal, which are deposited in large steel bins for loading out on the three railroad tracks and at both sides of the building. The slack size of coal is carried by means of a conveyor to the power plant, which is located near-by.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

While there is no decided improvement over the depressed condition of the market last week, most reports are more optimistic, and indicate a general steadying up in trade. Weather conditions still continue adverse for domestic, while on the other hand encouraging reports from industrial centers, especially in steel, are having a noticeably stimulating effect on the steam fuels.

Conditions on the Atlantic Coast are about normal and supplies good, although water freights continue high. There is a perceptible absence of new business, but the contract tonnage is heavy and there is no coal on demurrage. At Pittsburg domestic has fallen off, but steam continues good, and reports for November show a heavier tonnage moved all-rail than last year. It is believed there that stocking in anticipation of the coming wage conference will begin after the first of the year.

Trade in Ohio is quiet, but prices are firm. The weather has been warm and supplies are large, but steam is considered normal for this period. In states to the south conditions do not appear so favorable, and there is still evidence of a demoralized market.

A free supply of cars in the Middle West has resulted in overshipping the market, and conditions there are probably the worst in the country. Prices have slumped in some instances to the lowest point in a number of years, and the only chance for improvement in evidence is the resumption of a number of the large steel plants.

Mines in the Rocky Mountain states are mostly working full time, while on the Pacific Coast the weather is mild and trade continues normal or quiet.

Boston, Mass.

With colder weather, and a northeast storm preventing the movement of transportation, the situation is rather firmer than a week ago. A shortage of labor is rumored in the West Virginia fields, and receipts at the loading piers are beginning to be light. The arrivals of off-shore tonnage are understood to be more than usual, and no one here would be surprised to see a material advance in f.o.b. prices before the holidays are over. It is stated \$2.70 and \$2.75 have already been quoted for spot shipment at Hampton Roads. Mystic Wharf prices, on cars, Boston, are practically at the same level as for a fortnight past, namely, around \$4, although during the very mild spell 10 days ago, alongside prices for cargo lots were decidedly weaker.

On Georges Creek and the Pennsylvania soft coals at tidewater, there is no apparent change. Barges are still moving slowly, and have to be arranged for well ahead of requirements. Some of the better brands from Somerset County are netting \$1.30@1.35, at the mines, a higher level than has obtained for some time.

The supply of tonnage is still behind the demand, and while the \$1.15 rate was said to be had during the soft period last week, rates are now supposed to be back at \$1.25 for the larger vessels, Norfolk and Newport News to Boston.

New York

The bituminous market here at New York has held its own this week. While there has been only a small amount of new business coming in, contract demand has been steady and quite ample for the prompt disposition of arriving and standing tonnage at the New York piers. It is likely that shipments to New York tidewater are not relatively so heavy as a few months ago because now the demand from rail points is so large and absorbs such a big percentage of the production that the shipments which are being made to this market, are not much greater than the present needs. Nevertheless there is a large tonnage moving, as is evidenced by the fact that all of the New York piers have been extremely busy this week, dumping up to a large percentage of their capacity.

The mines supplying this market with steam coal are practically all working full time and it is interesting to note, notwithstanding this, the absence from this market, for the moment, of demurrage coal.

Shortage of marine transportation continues to be a source of worry to the coal trade and the markets in the East along the Sound would no doubt readily take up a larger tonnage, were boats for this trade more plentiful, but the weather has again been adverse to the prompt movement of tows.

Spot prices are not much changed; the bulk of the business now moving is on contract so that there is not enough spot demand to cause any substantial advance in prices.

Philadelphia, Penn.

The milder weather that has been prevailing in this vicinity opened the present week, although predictions are that there is likely to be cold weather and snow before the close of the week, and that snow-covered ground may be expected for the holidays.

Another week has passed, and yet no indications of a depression in the wholesale market. This is particularly true of the tidewater market, where all sizes are in much demand. Vessels are held up, awaiting the arrival of certain sizes of coal from the mines, especially stove and chestnut, and the relief that would naturally be expected from the slump in the local market, is not evident, although in a measure assisting somewhat.

The bituminous market still continues its on and off policy. Some of the operators approached state that business is fairly good, and others are down in the mouth, but still continue hopeful. High rates of freight at tidewater have had the effect of curtailing considerable tonnage that would otherwise go in this direction. As high as \$1.25 to Boston has been asked and paid.

Pittsburg

Bituminous—Domestic demand, which was quite good, fell off somewhat last week, but is expected to prove better this week. Manufacturing demand is good. There has not been a great deal of stocking yet, but a decided movement in this direction is expected, after the first of the year, in anticipation of a suspension after the present wage scale expires, Apr. 1. The strength of the general demand is shown by the fact that the leading interest in this district, disregarding shipments in the Lake trade, shipped more coal in November than in the corresponding month of last year. Prices are a trifle firmer in the past fortnight, by about 5c. a ton, and we advance quotations on nut, mine-run and ¾-in. by 5c. a ton and on 1¼-in. by 10c., quoting slack at 70@75c., against 65@75c., as follows: Nut, \$1.05@1.10; mine-run, \$1.10@1.15; ¾-in., \$1.20@1.25; 1¼-in., \$1.35@1.40; slack, 70@75c. per ton at mine, Pittsburg district. These prices apply on ordinary sales, but are occasionally shaded on odd lots which have to be moved.

Connellsville Coke—A little additional contracting for furnace coke for deliv-

ery in the new year has been done, and probably three-fourths of all the furnace coke to be covered at this time is now closed. This reckoning does not include cases in which furnaces not now provided with contracts may blow in, if the present improvement in the iron and steel industry continues for any length of time. Spot furnace coke continues very stiff and it is not easy to pick up any considerable tonnage at $1.60, the advance price quoted last week, while there are predictions the spot market will reach $1.70 before the end of the year. This, however, represents merely the usual movement at this time, and the market may be back to $1.50 in January unless general conditions have meanwhile improved. We continue to quote: Spot furnace, $1.60@1.65; contract furnace, first half, $1.60@1.65; year 1912, $1.65@@$1.75; prompt foundry, $1.80@1.90; contract foundry, $2@2.25, per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Dec. 9 at 319,130 tons, an increase of 3000 tons, and shipments at 3490 cars to Pittsburg, 4937 cars to points west and 1092 cars to points east, a total of 9519 cars, or 67 cars more than in the preceding week.

Baltimore, Md.

Warm weather conditions had a depressing effect on the Baltimore market during the week and, viewed as a whole, there was little to encourage the trade here. There has been an entire absence of seasonable weather for five days or more, and the high temperature has practically eliminated any signs of spot business, which proves quite profitable to operators, when the market is active.

A considerable tonnage moved from the mines in Maryland, West Virginia and other states, but it was shipped under contract, and this movement had little or no effect on the market, especially so far as prices were concerned.

What few sales were recorded outside of contract shipments throughout the week were for steam coal. The gas-coal market was absolutely stagnant.

Buffalo, N. Y.

The coal trade is still badly affected by the weather, even bituminous suffering severely, on account of its large use in the heating of office buildings, which have required little fuel as the thermometer has scarcely been down to freezing for 10 days. Still, considering the quiet state of the trade during the fall, the demand has been fair and promises to continue so.

With the return of seasonable weather there is every promise of a good general coal trade, although the stir is not expected to be sufficient to advance prices.

As a rule the mines in the bituminous regions are running on practically full time and there is no coal accumulating on track except where the railroads are failing to keep up with their work, which is reported in a few instances.

Bituminous prices are as formerly, with some added stiffness: $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack, with coke about the same, at $4.25 for best foundry, to $3.50 for stock coke.

Anthracite is suffering severely from warm weather. But for the great call for it through the fall the trade would be in poor condition. Lake shipments for the season have ceased, being 3,919,429 tons, as against 3,639,368 tons for 1910.

Cleveland, Ohio

According to reports, coal is moving pretty freely from the upper lake ports. Many of the vessels that are laid up at Fort William and Port Arthur are under charter, but at Duluth, where the fleet is much larger, only a few steamers have been tied up.

The steam trade does not show any great improvement as to demand or prices, excepting in slack. Youghiogheny slack coal has been plentiful with prices stiff. The domestic trade is slack on account of the extremely mild weather the past two weeks, but, according to weather reports, we are expecting a cold wave.

Prices in Ohio fields are: No. 8 slack, 75c.; mine-run, 90@95c.; ¾-in., $1@1.05; 1¼-in., $1.10@1.15; Middle district: slack, 75@80c.; mine-run, $1.05@1.10; ¾-in., $1.15@1.20; 1¼-in., $1.40@1.45; Pocahontas, mine-run, $1.10@1.15; lump, $2.15@2.20.

Columbus, Ohio

Continued warm and rainy weather has caused a let up in orders in the domestic trade and on the whole the market in the Buckeye State has been quiet. Another cause for the slack demand is the approach of the holidays, which is usually a signal for a falling off in orders from the consumer.

Prices are still fairly well maintained at the circular figures issued in September. There is no disposition as yet to advance the circular quotations, although there was some talk recently that an advance might be made some time in January.

Prices are ruling rather firm in all grades despite the weather conditions. In the steam trade the requisitions are coming up to the usual amount for the time of the year, although some slowness is reported in certain lines of manufacturing. The railroads are taking a larger amount of steam grades and in some cases there is a disposition to store in anticipation of a suspension.

Operations in Ohio fields have not been active lately because of the slackness in the domestic trade. In the Hocking Valley fields the output has been about 70 per cent. of the average and the same percentage prevails in the Jackson, Masillon and Cambridge fields. In the Pomeroy Bend field the output has been slightly larger. In eastern Ohio the production is also curtailed considerably because of the general softness of the trade.

Prices prevailing in Ohio fields are:

Domestic lump in the Hocking Valley	$1.50
Domestic lump in Pomeroy Bend district	1.60@1.75
Fancy grades of domestic coal	1.85@2.35
Three-quarter inch	1.35
Nut	1.15
Mine-run in eastern Ohio	0.95@1.05
Mine-run in the Hocking Valley	1.05@1.15
Coarse slack	0.35@0.45
Nut, pea and slack	0.40@0.50

Cincinnati, Ohio

Three weeks ago the car situation was so tense that coke racks were used to transport lump coal, while today it is just the reverse, and cars of all kinds and in any quantity desired are readily supplied. Unseasonably warm weather has prevailed for two weeks and the demand for both lump and steam coal is consequently much less. Wholesalers, holding contracts calling for a specified delivery, are being asked to delay as much as possible.

While the wholesalers and operators are accommodating their customers in this matter they are doing so at a distinct inconvenience to themselves. The request comes just at the time when the mines are turning out the maximum output per day, due to the fact that the miners are endeavoring to increase their Christmas pay checks.

There is probably more fuel being sold on demurrage here than for some time. The Northern markets consumed a part of it for a time but even that has fallen off so that there is not much relief now. In all cases, however, it is not believed that the sales have been of sufficient importance to interfere with the general level of prices.

Charleston, W. Va.

As far as output is concerned, there has been little or no change in this state during the past week over that of the previous week. There has, however, been some increase in price, which will insure the continuation of a number of operations that would otherwise have soon been compelled to close down.

The Smokeless Coal Association, which has had several meetings during the past few months, held one, last week, in Philadelphia, at which 98 per cent. of the

smokeless-coal operators on the Chesapeake & Ohio, the Norfolk & Western and the Virginia railways were represented. It was agreed among them that their future success depended upon the securing of a better price for their coal, and in order to secure the continuation of operations of many of the mines, the price of smokeless was advanced 10c. a ton. This, of course, applied to run-of-mine and tidewater shipments, which will net the operators $1.20 from the New River, Kanawha and Pocahontas fields, making all contracts hereafter $2.70 at tidewater.

Hampton Roads, Va.

Business at the Hampton Roads ports has been quite good during the past week. Notwithstanding the high coastwise and foreign steamship rates, several of the large shippers have been short of coal and compelled to buy from other agencies.

Prices are firm and fairly well maintained and there is a tendency for the coal operators and sales agencies to work together as regards both sales and prices. This is a different state of affairs from that which has obtained during the past year. The export business is growing in volume every month and will certainly be at its greatest during 1912. Several contracts have been made for foreign shipments, principally to South America and the Mediterranean ports, beginning Jan. 1.

Louisville, Ky.

A period of warm, rainy weather, combined with the approach of Christmas, has caused a slump in the local retail trade, and the dealers are loud in their complaints. Due to these conditions, the consumers are buying only what they actually require. There is plenty of coal available, both river and railroad, and the prices remain about as last week. Pittsburg lump is being sold as low as $3.50, and nut at $3.25. These prices are on a cash basis, however, and are due to the rate war recently started. Straight Creek is being offered at $3.75, and Jellico egg at $3.60. Anthracite, broken, egg, stove, nut and chestnut are quoted at $7.25 in carload lots, f.o.b. Louisville.

Wholesale prices are ranging as follows, f.o.b. mines: Straight Creek, block and lump, $2; Rich Mountain, of Genuine Jellico, $2.25; higher grades of nut and slack, 85c., and the cheaper grades, such as the Dean, 50@60 cents.

Nashville, Tenn.

Another week of warm and unseasonable weather finds the coal trade, as usual in this field, in a demoralized condition. While the operators are making a heroic effort to maintain prices on lump at $1.50 per ton, and have been fairly successful in doing so, there is no demand for coal at any price. It is not a question of price; the dealers have no business, and consequently no use for coal. There has been little life to business this season and it will take more than a few days of cold weather to stimulate the demand.

Owing to the small amount of lump coal produced during the past 10 days, there has naturally been a small amount of screenings, but there seems to be little, if any, better demand than has existed during the entire fall, and the price is practically unchanged.

Indianapolis

The general coal business is better than it was a month ago, and the operators are unquestionably more hopeful than they were then. This improvement has come about largely through the railroad companies' storing coal preparatory to any strike that may occur next spring. Many of the steel mills are now doing a good business and the chances are that they will continue active.

The price of Indiana coal has taken another drop, lump now selling at $2.75 @3 and Brazil block at $2.50@3.25. This is the lowest that Indiana coal has sold during the winter months for many years.

Minneapolis—St. Paul

The mild and open winter which has prevailed during the past month, is responsible for the quiet condition of affairs in the coal trade. Wholesalers do not look for better conditions until after Jan. 1, even if cold, severe weather does set in. So far as can be learned it appears that the dealer trade in this territory is well stocked up, and dealers are requesting orders to be held up for later shipment. Retail trade is holding up steadly but is by no means rushing.

The dock people are complaining at the slowness of demand on bituminous coals, while the anthracite trade seems to be fairly active and shipments are almost normal. Screenings from the docks are sold in the Twin Cities at ridiculously low prices.

Prices are not what they should be on all-rail coal from Indiana and Illinois, some Franklin County coal selling for as low as $1.50 at the mine. Miners will be only working about half time during the holiday season, and coal will be coming up slower. This will have a tendency to bolster up prices a little.

St. Louis, Mo.

The market is in much the same condition as last week, with the exception that some of the operators are down to where they are selling coal at less than cost of production. Everything took a slump, with the exception, of course, of anthracite and smokeless, and even screenings dropped off from 5c. to 10c. a ton in the face of what appeared to be a shortage on that size.

Several of the mines in the high-grade field, and also some in the Standard, have shut down until the demand gets better.

Franklin County coal under demurrage at East St. Louis sold for as low as $1.25, and Carterville lump and egg under demurrage has been selling as low as $1.15. Carterville mine-run under demurrage has been offered at 85c., and Standard mine-run at 72½c. The prevailing prices are:

Franklin County	
Lump and egg	$1.40@1.50
No. 1 nut	1.25@1.35
No. 2 nut	1.15@1.25
No. 3 nut	1.00@1.10
2-in. screenings	0.65@0.75
Carterville	
6-in. lump	$1.25@1.35
3x6-in. egg	1.20@1.30
No. 1 nut	1.15@1.20
No. 2 nut	1.00@1.10
No. 3 nut	1.00@1.05
2-in. screenings	0.55@0.65
Mine-run	0.95@1.00
No. 1 washed	1.50@1.60
No. 2 washed	1.20@1.30
No. 3 washed	1.15@1.25
No. 4 washed	0.80@0.90
No. 5 washed	0.40@0.50
Standard	
6-in. lump	$0 90@1.00
2-in. lump	0.85@0.95
3x6-in. egg	0.80@0.85
No. 1 nut	0.70@0.75
No. 2 nut	0 60@0.65
Screenings	0.40@0.45
Mt. Olive	
6-in. lump	$1.35
3-in. lump	1.25
3x6-in. egg	1.00
No. 1 nut	$0.80@0.90
No. 2 nut	0.75@0.80
2-in. screenings	0.40@0.45

The higher-grade coals from the inner district, such as Trenton, etc., are still holding at from $1.75 to $2. The tonnage from the Springfield district has practically ceased, and this is also the case with the Harrisburg and Gallatin Counties. Big Muddy coal is moving slowly at $2.25 for 6-in. lump and $2 for 2-in. lump.

There has been a marked decrease in the demand for anthracite, and practically all sizes have been under demurrage at East St. Louis during the past week. One commodity in good demand is coke, especially in the Northwest, and gashouse is bringing $4.75 at St. Louis, with byproduct at about $4.90.

Chicago

There is an apparently complete demoralization in the Chicago market, with a slash in prices in almost every direction. A free supply of coal, plenty of cars and little buying are the chief factors contributing to this situation.

The range of prices has been unusual. Smokeless lump and egg, which commanded $2.25 two weeks ago, is being disposed of at almost the buyer's own price. Starting around $2, the price vacillated for a time and then tumbled

to $1.90, from where it dropped soon after to $1.75, and even $1.60 and $1.50 in some instances.

Smokeless mine-run, which was firm a short time ago at $1.10, fell to 90c. and 85c. Hocking coal has felt the effect of the weak market, and went first to $3 and later to $2.90. On Franklin County coal the price in Chicago proper has remained around $1.50 for car-service coal; Carterville also has been weak. Screenings showed greater strength than was expected, the decline being not more than 10 cents.

Prices direct from the mines, in net tons, to retail dealers and steam users on spot shipments are as follows:

Sullivan County	*Chicago*	*F.o.b. Mines*
Dom stic lump....	$2.35@2.50	$1.50@1.65
Egg..............	2.30@2.40	1.45@1.55
Steam iump......	2.10	1.25
Screenings......	1.37@1.52	0.50@0 65
Springfield		
Domestic lump....	2.07@2.22	1.25@1.40
Steam lump......	1.97@2.07	1.15@1.25
Mine-run.........	1.83@1.87	1.00@1.05
Screenings........	1.32@1.42	0 50@0.60
Clinton		
Domestic lump....	2.12@2.27	1.35@1.50
Steam lump......	2.00@2.20	1.25@1.45
Mine-run.........	1.82@2.02	1.05@1.25
Screenings........	1.42@1.52	0.65@0.75
Pocahontas and New River		
Mine-run.........	$2.95@3.05	$0.90@1.00
Lump and egg....	3.65@3.90	1.60@1.85

Coke—Coke is quoted at: Connellsville, $4.50@4.65; Wise County, $4.50@4.65; byproduct, egg and stove, $4.95; byproduct, nut, $4.55@4.65; gashouse, $4.85.

Spokane, Wash.

The prices at Spokane remain unchanged and are the same quoted for the month past. The general condition at present seems to be most favorable, the weather not being too cold, and the supply is not decreasing as fast as usual at this time of the year. The shipments continue to be good, and the stocks are slowly being replenished.

Portland, Ore.

Portland has been fortunate in the weather line, so far this winter, which is not appreciated by the coal dealer, for certainly it has not stimulated the demand. The thermometer went down to 31 above, some weeks ago, which is by far the coldest since early last spring.

The demand for coal has been light, so the dealers have found no necessity to advance prices and values are exactly where they stood when the winter schedule went into effect in October. No new shipments have arrived from Australia, and none is due to arrive in the immediate future, although a few cargoes are *en route*. The period when fuel is most in demand in this section is during January, February and March, and it is to these months that the coal dealers look with the greatest interest.

Production and Transportation Statistics

Hampton Roads Piers

Coal handled at Hampton Roads piers to Dec. 9 of the present year was as follows:

Chesapeake & Ohio Ry.............	3,345,807
Virginia Ry.......................	1,908,678
Total..........................	5,254,485

The Chesapeake & Ohio Ry. Co.

The following is a comparative statement of the coal and coke traffic from the New River, Kanawha and Kentucky districts for the months of October, 1910 and 1911, in short tons:

COAL

To	1911	1910
Tidewater..............	335,655	322,779
East....................	185,168	167,219
West....................	1,025,887	886,333
Total..............	1,546,710	1,376,331
Bituminous from connections................	19,077	7,735
Anthracite from connections................	3,559	3,145
Grand total........	1,569,346	1,387,211

COKE

Tidewater..............	......	1,675
East....................	9,855	25,938
West....................	8,574	7,461
Total..............	18,429	35,074
From connections.......	487	2,735
Grand total........	18,916	37,809

firm tone for all descriptions. Approximate quotations are as follows:

Best Welsh steam coal................	$4.20
Seconds................................	4.02
Thirds..................................	3.78
Best dry coals.........................	4.02
Best Monmouthshire....................	3.78
Seconds................................	3.60
Best Cardiff small steam coal..........	2.16
Seconds................................	1.92

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days less 2½ per cent. discount.

Exports—Total exports for first 11 months of the current year were 58,805,355 tons, while for the same period last year they were 56,895,997 tons. The total exports of coal, coke and patented fuel for this period of the current year were 61,236,067 tons, and for last year 59,136,779.

Russia

Production in the Donets region for the first 8 months of the present year as compared with the same period last year was as follows in short tons:

	1910	1911
Bituminous..........	964,000	1,170,000
Anthracite............	166.000	193,000

Germany

The following is a comparative statement of the fuel production in the German Empire for the first 10 months of 1910 and 1911, together with imports and exports in metric tons:

GERMAN COAL PRODUCTION

	Production		Imports		Exports	
	1910	1911	1910	1911	1910	1911
Coal.....................	126,030,092	133,470,434	9,307,424	9,012,286	19,363,915	22,245,553
Lignite..................	56,284,894	60,292,946	6,139,200	5,813,871	50,112	48,366
Briquets.................	*16,098,545	*18,047,727	192,332	174,949	1,593,216	2,002,575
Coke.....................	19,393,499	20,818,326	531,859	497,380	3,335,579	3,718,323

*Includes subsequently reported quantities.

Norfolk & Western Ry. Co.

The following is a statement of shipments over the Norfolk & Western Ry. during November, 1911:

From	Commercial	Company	W. Va. Mines
Pocahontas field...	1,148,135	98,951	1,189,478
Tug River field....	141,914	42,320	184,234
Thacker field......	160,690	57,058	217,748
Kenova field......	70,439	11,587	82,026
Clinch Valley field.	96,198	8,023	......
Total..........	1,617,376	217,939	1,673,486

Coke shipments from the Pocahontas field were 99,339 tons.

Foreign Markets

Great Britain

The inquiry is not so active, but this is probably due to the fact that most buyers have completed their arrangements for loading before Christmas. For forward shipment the market displays a firm tone for all descriptions.

Shanghai, China

As was only to be expected under the circumstances there has been hardly any business done on this market owing to the revolution and the difficulties which have arisen on account of the inability to complete satisfactory banking and financing arrangements while the uncertainty lasts in the diplomatic situation. Prices have risen sharply in some cases.

Austria

Coal production in Austria for the first 9 months of the years 1910 and 1911 is as follows:

	1910	1911
Coal.................	10,323,734	11,008,690
Brown coal...........	18,398,089	18,710,953
Total mined........	28,721,823	29,719,643
Coke................	1,486,091	1,543,800
Briquets.............	244,408	254,882

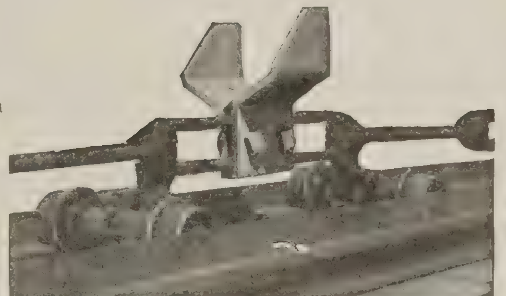
"Link-Belt" Car Hauls

Built for any capacity or to suit any conditions

"Link-Belt" Car Haul, 750-feet Centers
La Salle County Carbon Coal Company, Oglesby, Ill.

IN the installation shown the cars are automatically engaged by spring tilting hooks at shaft, carried up grade for a short distance, and then down grade to tipple. On changing from up to down grade the cars move by gravity from the tilting hooks to stationary retarding hooks placed slightly in advance. After dumping, the empty cars are automatically engaged and returned in the same manner. A single continuous moving chain, traveling in opposite directions on the same levels, handles both the loaded and empty cars. Capacity of haul, three cars per minute.

Dodge Chain
Employed for car hauls requiring both vertical and horizontal deflections.



Stationary Retarding Hook

We also Design and Build Machinery of every description for the efficient and economical handling of coal at the mine.

Write for Book No. 111 CA.

Tilting Hook for Up Hauls

SITUATIONS WANTED

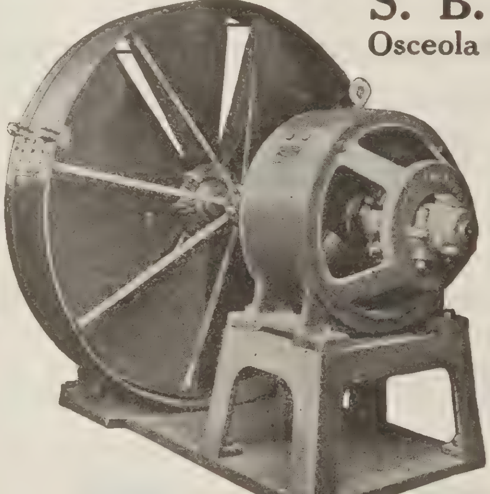
Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Position wanted as superintendent, mine foreman or engineer; 16 years' experience in mining; eight years at mining, eight years at engineering and assistant management; have Pennsylvania mine foreman's certificate; good surveyor and draftsman; knowledge of chemistry; age 30 years; uptodate and can get results. Address Box 4, care COAL AGE. Dec. 23.

Ever Hear of the Stine "Mountain" Type Fan?

It's a special fan we build for use in very inaccessible places. It's built in one man pieces throughout. The supporting boxes are made extra large so it can easily be mounted on timbers. It is a fan of excellent efficiency, splendidly adapted to its particular work. *Write. We'll gladly send full details.*

S. B. Stine
Osceola Mills, Pa.



A Man Can Ride All Day Without Getting Anywhere

A man can be mounted on the finest steed in the country.

Yet he can keep on riding around and around the block and never arrive anywhere.

An advertiser can buy space in the best technical paper in the United States.

Yet use that space to such little purpose that it will leave him with a big doubt in his mind as to the value of any advertising.

The thing that gets the advertiser *something*, however—that brings him *results*—is very simple.

It's copy.

It's what goes into the space the advertiser buys.

It's to the advertisement as a whole what the brain is to a man.

Coal Age has a corps of trained advertising men maintained for the sole purpose of helping advertisers in its columns to get *value* from their space.

They are here solely for the advertisers' use.

When in doubt write to

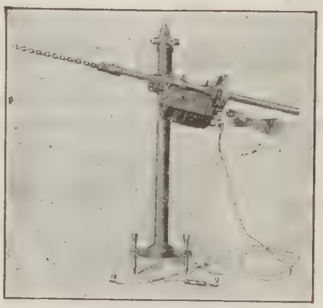
Howells Drills Bore The World's Coal



Our equipment has set the standard for 33 years. Thousands of "Howells" drills are in use throughout the World drilling into the hardest coal at the rate of seven feet per minute.

The Spry Type B Electric Drill

This drill is for circuits between 220 and 500 volts direct current. Consumes from 8 to 10 amperes and developes from 2 to 3 H.P. Weight, without post, clamp or augers, 100 lbs. Send for Catalog No. 28 showing complete line of hand and air drills.

COAL AGE

Vol. 1 NEW YORK, DECEMBER 30, 1911 No. 12

THE season of goodwill, kindly deeds, and new resolutions is with us. After months of strenuous endeavor, the world is weary and we all are glad that the machinery of life is momentarily stopped and the oil of charity applied.

It gives a chance to catch our breath, and besides, we can always jump farther, if we'll only stop, draw back and get a fresh start. The principal part of the balance most of us will strike when we close our ledger of accounts for the year, is experience; and if we have learned that sound discretion is not so much indicated by never making mistakes as by never repeating them, then we've capital a-plenty to start the New Year.

If any of us believe that during past months we've been dogmatic in our utterances, then let's hope kind Providence has taught us that it's possible for each one to be mistaken, and therefore how necessary is kindly consideration of views that differ from ours.

But you say,—in what way does the Yuletide directly affect coal men, and how does it concern us, aside from its strong appeal to our sentimental nature? The reply is, that this period of the year is characterized by a universal "stock-taking"; 'tis a time for making detailed inventories of goods on hand.

As foreman, superintendent, or manager of a mine, you haven't a store with merchandise on the shelves, but each of us does own and run a little shop, located just under our hair, and it's here we manufacture and sell a product known as ideas. The income and prosperity of each individual depend largely on the quality and character of the wares he peddles, although superior salesmanship will sometimes dispose of goods that are a bit shopworn.

However, since most of us are fortunate to get par for any article we sell, isn't it wise to start right now, clean off the counters, get rid of obsolete ideas and see that the stock remaining on the shelves of our shop is of modern design and recent manufacture?

Of course, there is more than one accepted style for some particular article, and it will frequently occur that two purchasers of equal intelligence will differ in their likes, but this only proves how necessary it is for the owner of the shop to be familiar with the history and development of the goods he deals in; otherwise he may sell an antiquated useless idea to a good customer, and as a result, be condemned ever after as a dispenser of ancient, impracticable information.

Therefore, in starting the New Year, let's not adhere too closely to the belief that because some one man successfully worked a particular mine by a certain method ten years ago, we can attain as favorable results today by following in his footsteps. Machines and motors have supplanted picks and mules; overcasts have been substituted for doors; steel is taking the place of wood in props and cars, and telephone connections underground are essential to modern practice.

Can't we resolve, then, at the beginning of this, another year, to hand out six-cylinder ideas instead of the two-cylinder type we've been supplying. It's also well to recognize that when we drive the same old mule down the same old furrow, day in and day out, the brain is taught to think one way, do one thing only, and even if we do that one thing well, the other powers of mind are in danger of atrophy.

No matter how great is the positive force that rests in us, complete results cannot be achieved unless some of the Christmas-spirit is carried through the year—the mantle of charity must be thrown around the faults of our fellow-beings. Too often we limit ourselves to a strictly business view of all matters, and strive for reputation rather than character. In this connection it is well to recall that character is what we really are, while reputation is only what we are thought to be. Nothing is so easy to attain, so hard to maintain, and of such all-around danger as reputation.

Electrical Symbols for Mine Maps

By H. H. Clark *

The Pennsylvania mining code requires maps showing the location of all electrical equipment in mines. These electric symbols are proposed for the consideration of electrical engineers and for the purpose of promoting uniformity of expression. Conductors are represented by a broken line with appropriate symbols showing their number and nature.

Some time ago the Bureau of Mines began the preparation of a list of symbols to be used in reporting mine examinations. This list was designed to cover electrical apparatus, and many other things as well. When the new Pennsylvania mine law went into effect, the list of electrical symbols was revised and enlarged with the idea that it might, at some future time, be of use to those interested in the preparation of mine maps for showing the location and character of electrical apparatus, as required by paragraph 14, section 1, article XI, of the new code.

Advantage of Symbols

If those interested in this matter should adopt one set of symbols for the purpose, at least two advantages would be gained: First, the advantages resulting from uniformity of practice which are too obvious to require discussion, and, second, every individual desiring to use symbols would not have to spend the time and thought necessary to develop a system of his own.

There is also another probable advantage. A system of symbols, to be of general application, must be considered from so many viewpoints and by so many different people that the resulting plan would be more complete, more flexible and more satisfactory than a list prepared under other conditions.

There is nothing absolute about a list of symbols; the characters are all arbitrary, although it is best to interrelate them when this does not involve complication. The main thing is to select characters that are distinctive, easily made and duplicated and not used for other purposes in the same field. Electrical apparatus is frequently represented by symbols in engineering work above ground, but, so far as I am aware, there is no published list of such symbols which has been formally approved by any organization, with the exception of one which has been prepared by the National Electrical Contractors' Association and approved by the American Institute of Architects. In preparing the list of symbols which is used by the bureau, certain characters were included which, in the past, have been quite generally used in electrical diagrams. As many of the National Electrical Contractors' symbols were used as seemed applicable, and the rest of the list consists of more or less arbitrary forms.

Symbolic Representation of Conductors

In making up the list of symbols it was comparatively simple to select characters for apparatus and machines, but the representation of conductors was not so easy. If there are only one or two conductors in an entry, they may be easily shown by lines of different colors or by lines made up of different arrangements of dots and dashes. If there are many conductors and the scale of the map is 200 ft. to the inch, this method is not so satisfactory.

The following method, which the bureau plans to try out, is general in its application. Although it will hardly be as clear as the line method when only one or two conductors are involved, it will probably be less confusing where several different circuits are to be shown on small-scale maps. A description of the method is as follows: Letters are used to indicate conductors; thus "T" denotes a trolley wire, "B" a bare, low-voltage conductor, etc. Figures are used in conjunction with the letters to denote the number of conductors of any kind. Thus "2 T" denotes two trolley wires and "3B" denotes three bare conductors. Other kinds of circuits are denoted by other letters. These letters are placed on the map along the side of an entry, to show what circuits are passing through that entry. Whenever a conductor is added or dropped, a new symbol is put on the map at the proper place, showing one more or one less letter, as the case may be.

Symbols for Machinery

The first figure shows the list of symbols covering machines and miscellaneous apparatus. This list shows some apparatus which is not used in every mine, while much of it is used in only a few mines. It is included, however, because it was the intention to make the list as complete as possible. The machine symbols are based upon past practice, which has become more or less standard by continued use. Explosion-proof motors are represented by inclosing in a square the symbol for the open motor. The transformer symbol is that used by the National Electrical Contractors' Association.

As to the miscellaneous list, the telephone symbol was selected as being distinctive and easily made and duplicated. The National Electrical Contractors' Association's symbol for a telephone is the outline of a telephone mouth-piece. This is suggestive, but it is not so easy to make and duplicate as the one finally selected. The old conventional symbol has

Note—Paper read, Dec. 20, before winter session of Coal Mining Institute of America, Pittsburg, Penn.

been used for ground connections with the addition of letters to show the character of the ground.

The second figure shows the symbols for conductors and switches. The application of the conductor symbols will be explained more fully on the third figure. The National Electrical Contractors' Association symbol, somewhat modified, has been used to represent switches. The inclosing square is used to designate explosion-proof construction.

An Elementary Example

The third figure shows in the simplest form the method of applying the conductor symbols. Only one entry is shown, the parallel entry being omitted for the sake of clearness. It has been suggested that the use of letters to indicate conductors be supplemented by a single colored or dotted line, which should extend as far as the electric wiring. The presence and extent of electrification would then be shown by this line and the specific character and number of the circuits could be learned from the symbols.

This plan appeals to me as having decided advantages. In Fig. 3 the presence shows that two bare wires run up the crosscut.

Returning to the main entry again, the symbol "TP" shows that the signal line is dropped just beyond the first face entry, but that the trolley and telephone lines continue as far as the symbol "T," which shows that beyond this point on the main entry there is no wiring except for motors. The symbol "TP" on the first left-face entry shows that both the trolley and the telephone lines run up this heading.

Another Installation

From Fig. 5 the appearance of the symbols can be judged, as applied to an actual mine map. The layout of the mine and the installment of electrical apparatus have been prepared merely to provide a framework for showing the symbols, and not for exemplification of correct mining methods. Only the outlines of the entries are shown as it is not necessary to show the complete map in order to indicate the location of the electrical apparatus. This mine does not have much electrical development and yet may be regarded as typical of many mines in the Pittsburg district. The rep- to the various butt entries as shown. From the junction of No. 1 North with the main entry a circuit of two bare conductors and also a telephone circuit run along the main entry to the pump room. The circuit is controlled at its starting point by a double-pole switch and the return circuit is grounded to the rail at this same point. In the pump room is located a 50-hp. direct-current motor of the open type, a switchboard, a telephone, and four incandescent lamps. The circuits running up the butt entries consist of two bare conductors controlled by a double-pole switch at the mouth of the entry, at which point the return circuit is grounded to the rail. This applies to entries Nos. 6, 8, 10, 12 and 14 West and to No. 8 East. The symbol "2TP" at the beginning of the parting shows where the double trolley begins.

An Elaborate Installation

Fig. 4 represents a mine using a great deal more electrical apparatus than the mine just discussed. In this case it is necessary to use about 30 of the symbols. The arrangement of the apparatus in this mine is slightly different from that in Fig. 5. It is assumed for the purpose of illustration that the power is taken from an underground substation at which point is installed a 300-kw. rotary converter fed by transformers having an aggregate capacity of 350 kw. The symbols show that there is a high-voltage lead-covered cable going down a bore-hole to the substation. This cable receives its power from an overhead transmission line and is protected by a lightning arrester. Marginal note No. 3 gives some additional information about this cable. In the underground substation, besides the transformer and the rotary converter,

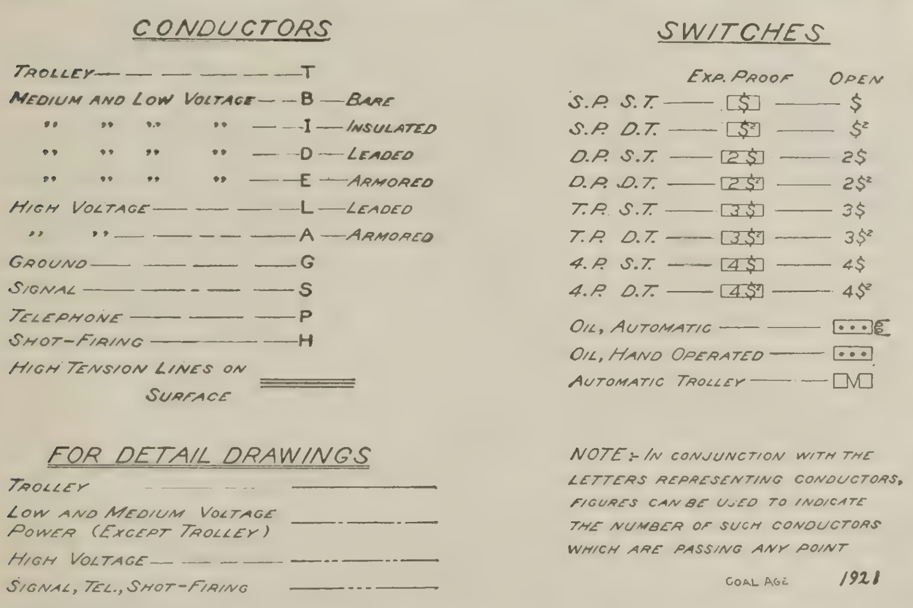

Fig. 2. Symbols for Conductors and Switches

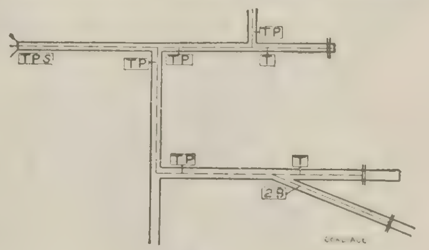

Fig. 3. Simple Electrical Equipment

of electric conductors of any sort is indicated by a dotted line, and the specific character of the conductors is shown by the letters in the rectangles alongside the entry. The letters show that a trolley wire, a telephone line and a signal wire all enter the drift mouth. All these lines run down the main entry as far as the first right face. The trolley and telephone lines run down the first right face entry as far as the first left butt entry. They turn in there and continue as far as the crosscut entry, where the telephone line is dropped, the trolley line continuing down the butt entry. The symbol "2B"

resentation of the electrical apparatus in this case requires the use of but nine of the symbols shown on the first two figures.
